Cimicifuga racemosa is a tall, stately plant, having a subterranean knotty rhizome, and a simple herbaceous stem, which rises from below to eight feet in height. The leaves are large, and ternately decompound, having oblong-ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, ward-like raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval ovary and sessile stigma. The fruit is an ovoid capsule containing numerous flat seeds. The plant grows in shady or rocky woods from southern New England to Wisconsin and southward, flowering in June and July. The drug is gathered for the market in Michigan, Indiana, Illinois, and the southern Applachians.

Description and Physical Properties.—"*Unground Cimicifuga.*—Rhizome more or less branching, from 2 to 15 cm. in length and from 1 to 2.5 cm. in thickness; externally dark brown, slightly annulate, the upper surface with numerous hard, erect, somewhat curved branches having deep, cup-shaped, radiating scars; lower and lateral surfaces marked by numerous root scars and occasional short roots; fracture horny; internally dark brown and waxy or whitish and mealy; bark thin, wood distinctly radiate and about the same thickness as the pith; odor slight; taste bitter and acrid. Roots nearly cylindrical or obtusely quadrangular from 3 to 12 cm. in length and from 1 to 3 mm. in thickness, externally dark brown and longitudinally wrinkled; fracture short; internally, cortex thin and dark brown, wood yellowish or light-brown, 4- to 6-rayed.

"*Structure.*—Rhizome with a yellowish-brown epidermal layer; cortex of starch-bearing parenchyma cells; tracheæ with bordered pores; wood-fibers numerous, thin-walled and strongly lignified; the vascular bundles separated by starch-bearing parenchyma; pith cells resembling those of the cortex. Roots with thin epidermis; endodermis distinct; fibro-vascular bundles 4 to 6, developed in older roots as separate collateral bundles.

"*Powdered Cimicifuga.*—Light to dark brown; starch grains numerous, single or compound, the individual grains spherical or more or less polygonal, each with a somewhat central cleft, from 0.003 to 0.015 mm. in diameter; fragments of tracheæ and of wood-fibers; irregular, yellowish-brown fragments of suberized epidermis made up of more or less tabular cells, which are sometimes elongated and considerably thickened." *U. S.*

For a detailed description of the microscopic character of the root, see *A. J. P.,* 1884, 460; also 1895, 121; Holm, *M. R.,* 1911, p. 6.

The roots "exhibit in transverse section from three to five wedge-shaped wood-bundles, separated by as many broad medullary rays. Both rhizome and roots are blackened by *test-solution of ferric chloride* (presence of tannic acid)." *Br.,* 1898.

The odor, though not strong, is peculiar and rather disagreeable, and is gradually lost with age. The drug of commerce is likely to be unintentionally admixed with other species of *Cimicifuga* and *Actæa.*

Cimicifuga yields some 15 to 20 per cent. of resin. The substance known as *cimicifugin,* or *macrotin,* is made by pouring a concentrated tincture of the drug into a large volume of water whereby a mixture of resinous and other bodies is precipitated. Finnemore has made a systematic examination (*P. J.,* 1910, lxxxv, p. 142, 178) of this rhizome. He found besides palmitic, oleic, also isoferulic acid, 3 crystalline bodies apparently alcohols, phytosterol, and indications of alkaloid. There appears to be present also a crystallizable bitter principle to which the name *racemosin* has been applied. There is no evidence that any of these substances are physiologically important. The principle reported many years ago by Conarb (*A. J. P.,* 1871) was probably an artefact as subsequent investigators have been unable to confirm his results.

Uses.—In 1831 cimicifuga was introduced to the notice of the profession by Young. In overdoses it is said to cause general relaxation, vertigo, tremors, decided reduction of the pulse; occasionally it causes vomiting, but its emetic action is never violent, and is probably simply the result of a mild gastric irritation. In large doses it produces giddiness, with intense headache and prostration. It has been found by R. Hutchinson to cause in frogs complete anesthesia by a direct action upon the sensory side of the spinal cord. The same observer noted that toxic doses produce in mammals slowing of the pulse and fall of the arterial pressure, results which appear to be due in part to a direct depressant action upon the heart muscle or its ganglia, in part to a paralysis of the vasomotor center. Clinical experience has shown this drug to be a useful remedy in the treatment of *chorea.* It has also been employed, though with less certainty of benefit, in *chronic rheumatism, urticaria, neuralgia,* and *dysmenorrhea.* It is also asserted to act as a specific in *tinnitus aurium.*

In *chorea* it is necessary to give large doses. The proper method of administration is to start with about fifteen minims of the fluidextract three times a day, increasing one minim daily until the occurrence of frontal headache or improvement in the condition. The practitioners calling themselves eclectics use, under the name of *cimicifugin,* or *macrotin,* an impure resin obtained by precipitating a saturated tincture of the root with water; dose, a grain or two (0.065–0.13 Gm.). (See *N. J. Med Rep.,* viii, 247.)

Dose, of powdered cimicifuga, five to thirty grains (0.3–2.0 Gm.).

Off. Prep.—Fluidextractum Cimicifugæ, *U. S.;* Elixir Tongæ et Salicylatis Compositum (from Fluidextract), *N. F.;* Syrupus Cimicifugæ Compositus (from Fluidextract), *N. F.;* Tinctura Cimicifugæ, *N. F.*

CINCHONA. U. S. (Br.)

CINCHONA Cinch. [Peruvian Bark]

"Cinchona is the dried bark of *Cinchona succirubra* Pavon or of its hybrids, known in commerce as Red Cinchona or of *Cinchona Ledgeriana* Moens, *Cinchona Calisaya* Weddell and of hybrids of these with other species of *Cinchona,* known in commerce as Calisaya Bark or Yellow Cinchona (Fam. *Rubiaceæ*). Cinchona yields not less than 5 per cent. of the alkaloids of Cinchona." *U. S.*

"Red Cinchona Bark is the dried bark of the Cinchona succirubra, *Pav.*" *Br.*

Cinchonæ Rubræ Cortex, *Br.;* Red Cinchona Bark; Cortex Chinæ Ruber, Quinquina, *Fr.;* Cortex Chinæ, *P. G.;* Chinarinde, Rothe Chinarinde, *G.;* China, *It.;* Quina, *Sp.*

The U. S. recognizes under the name of cinchona any one of three species of bark, but the Br. recognizes only the *C. succiruba.* Formerly the U. S. recognized this under a distinct title of *Cinchona rubra.*

History.

There is no certain evidence that the medicinal properties of cinchona bark were known to the natives. The first authentic record of its use was in 1630 when Francisco Lopez de Canizares, Corregidor of the province of Loxa in southern Peru, was cured of a malarial fever. One tradition ascribes his treatment to an old Indian medicine-man, while according to others the original prescriber of the bark was a Jesuit priest. A few years later the wife of the Viceroy of Peru—Ana de Osorio, Countess of Chinchon—being seized with the same malady, Canizares sent to her physician, Dr. Juan del Vega, a package of the bark which was used upon her with the same gratifying results. In 1639 the Countess of Chinchon returning to Spain carried some of this wonderful remedy to Europe, where she distributed it among the afflicted in her extensive domain. Dr. del Vega also took some of the bark back to Europe with him, but the first general introduction of the drug into Europe was by the Order of Jesuits who for many years had a monopoly of the distribution, hence the popular mediæval name of *Pulvis Jesuiticus.* The remedy rapidly attracted tremendous attention and was sold in the 17th century at fabulous prices. In 1679 the English physician Sir Robert Talbot (or Talbor) cured the Dauphin of France of a malarial fever and sold his secret to Louis XIV for 2000 Louis d'or and a title of nobility.

For nearly a hundred years the source of the bark was entirely unknown to Europeans, but in 1735 Charles Marie de la Condamine, the commander of a scientific expedition sent out by the French government, collected a number of young plants which he transported down the Amazon River for 2000 miles, but all of them were lost in a storm which overtook his fleet in the mouth of the river. He, however, succeeded in bringing back specimens of the tree, the description of which he published in 1738.

Linné, from La Condamine's specimens, established a new genus which he named, in honor of the Countess of Chinchon, cinchona. The botanist of this expedition, Joseph de Jussieu, remained for 15 years in South America studying the sources of the drug, but on the eve of sailing for France, was robbed of his fine collection of young cinchona plants. The loss of the rewards of his long labor drove him insane. In 1846 Dr. Weddell succeeded in bringing back to Paris some seeds from which a few cinchona trees were grown in the Jardin des Plantes in Paris. The first considerable exportation of cinchona trees were brought back by the Dutch botanist Hasskarl in 1854 and afforded the beginning of the cinchona plantation in the Island of Java. This plantation, however, did not flourish at first. In 1859 the English government sent out an expedition under Clements R. Markham who succeeded in establishing a plantation in the Neilgherry hills of India. Among other botanists who contributed to the early knowledge of this species may be mentioned especially Ruiz and Pavon, Ledger, Karsten, etc. At the present time there are recognized more than 30 species of the genus, many of which, however, are medicinally unimportant.

The word quinine is derived from the Indian word "quina" or "kina," which means a bark.

Geographical Distribution.

The Cinchona trees are natives exclusively of South America. In that continent, however, they are widely diffused, extending from the 19th degree of south latitude, to about the 10th degree of north latitude. They follow, in this distance, the circuitous course of the great mountain ranges, and for the most part occupy the eastern slope of the second range of the Cordilleras. They require a moderate and equable temperature and an abundant and fairly constant supply of water. Irrigation cannot supply the place of a humid climate, for the atmosphere as well as the soil must be well charged with moisture. A certain amount of dry weather is, however, required for the ripening of the capsules. Free drainage is an important condition. In their natural habitat the temperature rarely goes below 2° C. or above 21° C.

The limits of altitude and climatic conditions are closely drawn. In the most southern districts, the trees descend to about 2500 feet, while in the warmest regions they scarcely ascend to the 10,000-foot level. The individual species are for the most part rigidly restricted as to altitude and latitude, and, indeed, it has not always been found easy to detect the climatic conditions which would cause one species or variety to thrive while another very near it would languish. This is especially true of the more valuable forms.

The ever increasing demand for cinchona and the wanton carelessness in methods of collecting the bark, made such terrible inroads on the natural supplies that as early as the beginning of the 19th century the necessity of cinchona culture was universally recognized. It was this solicitude for a future source of a substance that had become almost essential for human civilization, that led to the repeated efforts of various governments to establish plantations in other parts of the tropics.

The earliest cinchona plantation was in Java, there being in that island in the year 1860, 947,000 young cinchona plants, most of them, however, being of species worthless as medicine. The second plantation was that started in India by Markham in 1861. In 1865 Chas. Ledger obtained some seeds of the superior species of cinchona known today by his name, which he sold to the Dutch government from which they grow what is generally regarded as the finest variety of bark. There are at present large plantations in Java, Southern India, in Sikkim, Darjeeling, Bengal, Lingmulla, in Bombay, in the Valley of Kangra and in the Punjab. The plantations which were established in Ceylon have been in recent years largely abandoned in favor of tea culture. The Portuguese have established plantations on the West Coast of Africa which are now yielding commercial quantities. A small amount of wild cinchona still appears in the market and the tree is being cultivated artificially in South America. The most important plantations are in the head-water districts of the Beni affluents of the Amazon in Bolivia; a large plantation in the United States of Colombia is also commercially productive and a smaller one in Ecuador. In 1918 the Igorot Exchange, a missionary institution at Sagada on the Island of Luzon, obtained seeds of the *C. Ledgeriana* from the plantation at Ootacamund, Madras, and this species is now growing in the mountains around Sagada in the Philippines. Successful plantings have also been made in East Africa of *C. ledgeriana, C. succiruba, C. robusta* and hybrids. In 1918, an examination of these barks indicated as high as 8.41 per cent. of quinine.

The history of cinchona cultivation affords a striking illustration of the importance of government aid in the establishment of a new industry of this kind. The early and repeated disappointments and failures, owing to the natural obstacles in the way of securing stocks, and to an almost total ignorance of the conditions determining the successful propagation and growth of the plant, and the composition of its bark, were such as to have discouraged the most hopeful of private enterprises. Repeated and expensive expeditions were necessary before the first transplantings were accomplished, and these stocks were preserved and propagated only through the instrumentality of well appointed public gardens and plantations. In Java, after these early difficulties had been surmounted and success apparently attained, it was found that owing to cross fertilization much of the progeny was entirely worthless, and the work of propagation had to be begun anew. The same difficulty was encountered elsewhere, and the slow and expensive method of propagation by cuttings was largely resorted to. In Ceylon the public was slow to become interested, and the officials were obliged not only to give away the young plants, but to solicit experiments with them as a personal favor. In Jamaica a hurricane visited the young and flourishing plantations and almost completely destroyed them. But at length, in spite of all, not only were thriving and permanent government plantations established, but private capital and enterprise upon a vast scale were enlisted. The question of commercial success is dominated not simply by climatological surroundings, but also by the price of labor.

The total world production of cinchona bark is today probably over 25 million pounds of which nearly 90 per cent. is produced in the Island of Java.

For detailed accounts of the Javanese cinchona industry see Howard (*J. Soc. Chem. Ind.*, 1906, p. 97) and Blokzeyl (*Ph. Era*, 1920, p. 69).

Description of Plants.

As the result of much experimentation, practical growers of cinchona have limited their efforts to the cultivation of the four species described below.

C. Calisaya Weddell yields the *Calisaya bark* or *Yellow Cinchona.* It is a tall tree, usually surpassing those about it, the trunk often more than two feet in diameter. Leaves petiolate, the blade ovate-oblong to slightly obovate, 7 to 17.5 cm. long by 2.5 to 7 cm. broad, obtuse, the base acute or slightly attenuated, very thin, smooth, and, especially below, with a satiny luster, above dark green, below emerald-green or deep purple-green, scrobiculate, the glands scarcely visible above. Stipules oblong, about equalling the petioles, very smooth, very obtuse. Panicles ovate to subcorymbose. Calyx pubescent, with a cup-shaped limb and short triangular teeth. Corolla rose-colored (in cultivation often white or nearly so), the tube cylindrical and about 8 mm. long, the laciniæ more deeply colored, the edges white-hairy. Stamens included. Capsule ovate, scarcely as long as the flowers. Seeds elliptical lanceolate, the margin irregularly fimbriate-toothed. The species presents many forms, and two varieties are recognized.

C. Ledgeriana Moens., formerly recognized as a variety of *C. Calisaya,* differs from the type chiefly in its thicker, narrower, oblong leaves, with attenuate base, often bluish-green below. It yields a thick and remarkably rich bark, and is probably the most valued of all the cinchonas. This species was named in honor of Ledger, who first brought seed of this species from Bolivia.

C. succirubra Pavon, from which comes the *Red cinchona,* has an extreme size even greater than that of the last. Branches silvery. Petiole pubescent, leaf ovate to oval, acute with a very short point, the base more or less narrowing, often 6 to 9 inches, dark green and smooth above, below paler and pubescent to a variable degree, especially on the veins, not scrobiculate, the margin slightly revolute. Stipules entire, oblong, obtuse subamplexicaul. Flowers much as in the last, but rather smaller. Fruit lanceolate.

C. officinalis Hooker fil.—Petioles smooth, cylindrical, and, like the veins, reddish; blade 10 to 12.5 cm. long, varying from broadly oval to lanceolate, acute at both ends, the margins usually recurved, smooth and deep green above, paler, but bright green below, scrobiculate, the principal veins pubescent. Stipules equalling the petioles, ovate, acute, entire, pubescent. Flowers and fruit much as in *C. Calisaya.* Widely distributed in the equatorial Andes, at an elevation of from 5000 to 7500 feet. The source of the barks known as Pale, Crown, Loxa, Cuenca, and Huanuco. This is the original species, upon which the genus *Cinchona* was founded.

The specific variations produced by hybridization in the above characters may not be here considered, though it may be stated that they are entirely characteristic. The parentage of a hybrid is ordinarily fully and strongly indicated in its appearance. As a rule, also, the alkaloidal yield takes a mean between that of the parents, but sometimes this is conspicuously not the case. Goris and Reimers (*Trav. Lab. Nat. méd. Ecol. supe. Pharm.*, in *Bot. Centralbl.*, 1906, p. 462) pointed out the use of *Cinchona robusta* Trimen as a collective name for all hybrids of *C. succirubra* and *C. officinalis.* Rosenthaler gives an account of the structural characteristics and alkaloidal content of *C. robusta* and other cinchona hybrids produced by grafting. (*B. P. G.*, 1908, p. 126.)

Methods of Cultivation and Collection of Bark.

The history of Cinchona cultivation teems with evidence as to the difficulty of obtaining pure seeds, owing to the tendency of the plants towards cross-pollination. In every locality where the industry has been established has the disgust of the gardener been excited by the discovery that the plants which he had reared with great care, and upon which he had based great expectations, were contaminated by the admixture of foreign pollen. This was especially true in case of the earlier attempts, before this tendency had become known. Experience at length established the fact that absolute isolation of the seed-trees was essential. One of the curious developments of these experiments was the fact, already referred to, that the value of the progeny was not always assured by the value of its parentage. Some of the hybrids, even when least expected, would develop a surprisingly rich yield; and this tendency has been utilized to develop the most valuable stocks in existence. Propagation by cuttings, extensively practised in some localities, has been found too slow and expensive to become general. A thorough preparation of the soil is as beneficial in the case of cinchona as in that of other crops. Thorough tillage after transplantation is also essential, a free growth of weeds meaning destruction to a large number of the young trees. The cultivation of a secondary crop between the rows of trees is, however, practicable. A large percentage of profit depends upon the selection of a suitable age for collecting the bark. There comes a time when the use of the ground for starting a new crop is more valuable than the gain by permitting the present crop to remain, and after some years an actual deterioration of the bark sets in. This age is not the same for all the trees in the plantation. Several years' difference may occur in the maturing of trees germinated at the same time. In the case of calisaya it occurs at from six to nine years from seed, and its indication is the "chicken-leg" scaliness of the bark. The "officinalis" matures somewhat less early.

Four methods of collecting the bark are in vogue, these being variously modified in different sections. The first is *uprooting,* the most primitive, by which the trees are simply uprooted at the proper age, and the ground replanted. The barks of root, stem, and branches are preserved and marketed separately. The second method is *coppicing,* by which, after peeling a quill from the lower portion of the trunk, the latter is cut a few inches from the ground and the remainder of the stem bark and the branch bark is removed. The "coppice" is formed by a second growth of two shoots from each of the stumps. A second coppice is commonly grown, and this is harvested by uprooting. By the third method, *scraping,* the outer bark is scraped off, leaving the liber untouched. This has been found especially applicable to young trees, in which the second growth of bark is rapidly formed and contains 20 to 30 per cent. more alkaloid than that which has been taken off. It seems to be a general opinion among the planters that scraping checks the growth of the tree after it is five years old, so that from three to five years is the age at which it is best practised. The fourth method is known as *mossing.* It having been noticed that the cinchona alkaloids, especially in any other form than that of sulphate, were apt, on exposure to the direct light of the sun, to become reddened by the generation of coloring matter, at the expense of the alkaloid, it was a very natural inference that a similar change might take place in the living plant, as a consequence of which the proportion of alkaloids they were capable of producing might be greatly diminished. It was also observed that the bark upon that side of the tree where the sun struck it was less rich than that upon the shady side. To obviate this presumed effect, MacIvor was induced to make the experiment of covering the stems of the growing trees with a layer of moss, so as to completely protect the bark against the influence of sunlight. The result was favorable beyond all expectation, and the yield of alkaloids in the bark thus protected is said to be doubled, tripled, or increased even in larger proportion. A tree can thus be made continuously productive; for if a slip is removed longitudinally from the trunk, from top to bottom, by covering the decorticated portion with moss, the bark is renewed at least as rich as previously in the alkaloids, while from time to time other strips may be taken, until the whole of the old bark is removed, and the new ready for removal by a repetition of the same process; and the tree is thus preserved indefinitely, probably for the whole normal length of its life. Hooper says that renewed bark is always of greater value than the mossed, and mossed than the natural, so long as the trees are under twenty years old, for it has been found that after that time the bark ceases to thicken, and the alkaloids remain stationary or even decrease. Perhaps twenty years is even too old. The practical difficulty with the process is that it requires skilled workmen, not always attainable, and hence the "coppicing system" still largely prevails in India.

The bark which is stripped from the trunk of the tree is known as "quina tabla" and that which is stripped from the branches is called "quina canuto" or "quill." The quills, after thoroughly drying, are carefuly packed in bales, or preferably in boxes, to avoid breakage, and are marketed in packages of from 100 to 250 pounds. Large quantities of cultivated bark are still marketed in this way, but, increasing competition having lowered prices so that the economy in freight has become a very important item, most of the bark is now broken up, and its bulk even reduced by high pressure.

By scientific methods of arboriculture the quality of bark produced has been greatly improved. This is well shown by the facts that in 1889 the average percentage of quinine (calculated as sulphate) in Java bark was 4; in 1893 it has risin to 4.6; while in the five years, from 1900 to 1904 inclusive, the average quinine percentage of all the Java barks sold in the Amsterdam market was 5.37; in 1924 it was 6 per cent.

For some years, in India, the attempt was made largely to increase the general average in total alkaloids rather than in quinine, so as to increase the production of the impure alkaloids which are so largely used as febrifuges in the British East Indies. Of recent years, however, even in India, efforts have been directed to the obtaining of quinine rather than of inferior alkaloids.

One of the most important developments of the modern bark trade is the fixing of the price in accordance with the quality as determined by assay. The most accurate method of selecting a characteristic sample for assay is a subject which has received much study, without the discovery of any method which does not depend for its value upon the discrimination and care exercised in its employment. The plan which is regarded as the safest, is to take a given weight, say eight ounces, from the inner portion of each package constituting the lot, mix and powder the whole of it, and furnish to applicants the required amount of the resulting powder. If any portion of any bale or bales is damaged, care is taken to add a proportionately large fragment of such portion. The bark is then recorded as containing so many units, a "unit" being each per cent. of quinine contained in a pound of bark. In rich bark the units are of course worth more than in poor, owing to the increased yield of alkaloid for the same cost of manufacture.

The finer appearing packages of unbroken bark, having been marketed at greater cost, are necessarily held at higher prices. Possessing no special value for manufacturing purposes, these fall to the share of the druggist, but at higher prices than broken bark of the same richness. This fact has led to the recognition of two distinct classes, known as *manufacturers' bark* and *druggists' bark*. Druggists' bark, though in quills or unbroken pieces, and of a much finer appearance than manufacturers' bark, is, on the average, inferior in quinine percentage. The druggists' bark finds its entrance into commerce through various channels but the bulk of the cinchona trade, including practically all that is known as manufacturers' bark, centers in Amsterdam and London; of these marts that at Amsterdam is much the more important. The bark which is sold in Amsterdam comes almost exclusively from Java; that in London from India and South America. Manufacturers' bark is sold, without respect to its physical characters or place of origin, entirely by its chemical analysis, the buyer in London being furnished with samples of the different lots of the bark sufficient time before the sale to enable him to make his own analysis, while in Amsterdam the percentage of quinine sulphate in any lot is given in the catalogue and often tagged upon the bale.

At present the commercial cinchona barks entering the United States come from plants cultivated in Java and India and from trees growing wild in South America. Java cinchona either comes direct or through London or Amsterdam. Indian cinchona comes through London or direct from India. South American cinchona comes direct from Cartagena, Colombia, from La Paz, Bolivia and from Guayaquil, Ecuador.

Cinchona barks have been divided according to their external form as follows: (1) the small chips or broken bark, referring in large part to the root bark, and to other bark broken for close packing; (2) the shaved bark, referring to some root bark and to stem bark taken from dry stems, but chiefly to branch bark; (3) the quill bark, referring to natural bark taken from the stem and root in quill form, this including the uncultivated pale bark and all the varieties of cultivated bark; and (4) the renewed and mossed bark, which may be of any cultivated variety.

In structure the root barks correspond very closely to the stem barks of the same variety. They can be readily distinguished from the latter by being thinner, having lighter external and darker inner color, greater softness, and twisted or contorted shape. They occur in short, irregular quills or chips, or sometimes as shavings, and contain very much more dust than any other form. Except partly as regards structure, the description of stem barks will not apply to branch barks of the same variety, for the characteristic markings do not appear in the young condition. The branch bark appears in shavings, to the inner surfaces of many of which more or less wood adheres. If the branches were shaved while yet fresh, these shavings will be more or less rolled up and curled; but if dry before being removed, this rolling and curling will not occur. Shaved bark taken from living trees is thin, soft, and brittle, consisting of the outer bark only. The large quills are of uniform length from the same plantation, but not necessarily so from different plantation or different sections. They are commonly from two to three feet in length, but some have been marketed having a length of five feet. Usually they represent the entire circumference of the stem, but occasionally only half of it. In drying they roll up very tightly from one or both edges, and rarely one will be wholly or partly involved in another. The periderm, with all its markings, remains intact, and no other form so well displays the natural appearance as this. Mossed bark differs from natural stem bark in its great thickness and weight, less breadth of the quills, freedom from lichens, very dark color, and rough, corrugated or warty surface. The outer bark or cellular portion bears a greater ratio to the inner or fibrous portion than in natural bark. Renewed bark is lighter, both in color and weight, thinner, soft and brittle, and marked by a very peculiar external smoothness, sometimes very marked indeed. In its general appearance it is strikingly like a root bark, except for the relative straightness of its fibers. Like the mossed bark, it is in narrow, only partly rolled quills or bands, and is entirely free from lichens.

As they differ so greatly among themselves in coloration, lichen-growth, degree and form of exfoliation, structure and consequent fracture, there are but few characters which can be combined in a general description of the Cinchona barks which we consider. The external color varies from light ashy gray to nearly black, the inner varies less in its shades of yellow-brown and red-brown. All are more or less bitter, and most are astringent, but only Loxa bark has a distinctive odor. The fracture is never very long-splintery and never tough. As to structure, the bast fibers are loosely arranged, the radial rows being neither continuous nor very long. The fibers themselves are always unbranched, which distinguishes the true from the false barks, are rather short and obtuse, brittle, and usually easily detached from the bark. Laticiferous ducts and stone-cells may or may not be present. The former become less conspicuous as the bark grows older, so that their relative absence becomes indicative of a stage in which the due proportion of alkaloid should have been acquired.

It may be noted here that by far the greater portion of the alkaloid, particularly quinine, is stored in the outer bark, though that in the inner bark is in a purer state. The latter is not stored in the fibers, but in the cellular tissue between them.

The classification of barks by color refers chiefly to the powder. These colors, never regarded as absolutely characteristic as the three barks, yellow, red and pale, exhibit gradations by which they mingled at their extremes, have become even more indistinct, because of hybridization. The U. S. Pharmacopœia classifies as *Yellow Cinchona* either the *C. Ledgeriana* or *C. Calisaya* and as *Red Cinchona* the *C. Succirubra,* and their respective hybrids.

Description and Physical Properties.—"*Unground Cinchona.*—In quills or curved pieces or in broken fragments; bark from 2 to 8 mm. in thickness; externally brown or reddish-brown, usually with white or gray lichens, more or less roughened with corky ridges or protuberances, and with transverse fissures, rarely numerous or much intersected and having their sides sloping (Red Cinchona), or with numerous intersecting transverse and longitudinal fissures having nearly vertical sides (Yellow Cinchona); inner surface brown or reddish-brown and striate; fracture short and granular in the outer bark, rather splintery in the inner bark; odor faintly aromatic; taste astringent and very bitter.

"*Structure.*—Cork, frequently bearing dense masses of lichen tissues on its outer surface, conissts of rectangular, thin-walled cells with brown contents; parenchyma brown-walled, containing starch grains, or in some widely scattered cells microcrystals; laticiferous ducts widely separated in a single row near the inner edge of the primary cortex, circular or oval in transverse section, up to 0.120 mm. in diameter; medullary rays usually 1 to 3 cells wide with rectangular thin-walled cells, frequently tangentially elongated in the outer part of the ray; bast-fibers numerous, isolated or in small groups between the medullary rays.

"*Powdered Cinchona.*—Brown; bast-fibers, frequently whole, spindle-shaped, from 0.30 to 1.35 mm. in length, and from 0.050 to 0.135 mm. in width, with thick, strongly lignified, lamellated walls having numerous simple or branched pores; parenchyma and cork fragments brown; starch grains inconspicuous, single or 2- to 5-compound, up to 0.020 mm. in diameter; sphenoidal microcrystals very minute." *U. S.*

In the British Pharmacopœia it is described as: "In quilled or curved pieces, length varying from 5 to 30 cm. or more; usually from about 2.5 to 6 mm. thick; cork brownish or reddish-brown, with longitudinal ridges which are most apparent in the branch bark, and sometimes with reddish warts; inner surface brick-red or deep reddish-brown, irregularly and coarsely striated; fracture shortly fibrous in the smaller, and finely fibrous in the larger, pieces. In transverse section in the cortex, cells filled with minute crystals of calcium oxalate, and also large secretion tubes; in the bast numerous, large strongly-thickened fibers usually 0.050 to 0.070 mm. wide and about 1 mm. long, isolated or in small groups. The powdered Bark is brownish or reddish-brown, exhibits abundant parenchymatous tissue with brownish cell-walls, and often with brownish contents, small starch grains, and large isolated bast fibers about 0.060 mm. in diameter, with distinctly striated walls. No marked odor; taste bitter and somewhat astringent." *Br.*

Yellow bark, or *calisaya,* has lichens thin and closely adherent, not rendering it shaggy. External markings very characteristic, consisting of a very light longitudinal ridging or none at all, but of numerous transverse and longitudinal fissures or cracks, the presence and arrangement of which constitute the chief characteristics of Calisaya. Upon the young stems and branches they do not appear. The first to appear are the usually large primary fissures, which encircle the stem at the nodes, or points where pairs of leaves once stood. Subsequently, numerous smaller secondary transverse fissures appear upon the internodes, and these quickly become connected and crossed by longitudinal cracks, thus dividing the periderm up into more or less quadrangular checks, which may remain attached or fall away. This gives to mature Calisaya bark an appearance of scaliness like that upon the tarsus of a fowl, and this is known to the South American collectors by a term which signifies the "chicken-leg appearance." It has also been spoken of as a "carving-like" marking. Like the roughness upon a musk-melon, its great development is regarded as an indication of high quality, and especially is this true of a close proximity of the primary fissures. This roughness is also regarded as a sure indication of maturity. There are excellent distinctions between these and the somewhat similar fissures upon the bark of *C. officinalis.* In the latter they are coarser and more gaping. Even more important is the absence from Pale Bark of most of the longitudinal cracks, so that it does not become "chicken-legged," or at most only very slightly so. The external color of Yellow Bark is lighter than that of the Pale Bark. Longitudinal ridges are few if any, short, irregular, and inconspicuous. In fine South American bark some very small bright-red spots can be detected upon the periderm. East Indian Calisaya can commonly be recognized by its somewhat dingy or brownish shade of gray, the gray of the South American bark being bright and somewhat bluish-steel-colored.

In structure, the zone of large, rather numerous laticiterous ducts just outside the bast is conspicuous in young, and therefore inferior, samples. The rather small bast fibers are loosely scattered, almost uniformly single or a radial arrangement being apparent. The fracture is rough-splintery, though not coarse. Stone cells few or none. Odorless, more bitter, and less astringent than the Pale Bark. Ledger Bark is the same as Calisaya in all its essential characters, but does not reach so great a size. In hybrids of Calisaya with succirubra the characters and quality of the latter appear to predominate.

Yellow Cinchona is scarcely collected in a wild state, but is cultivated in all plantations. It is the largest quinine yielder, its amount being 70 to 80 per cent. of the total alkaloids contained in the bark. The var. *Ledgeriana* yields a very valuable hybrid bark with *C. succirubra*. *C. Calisaya* also hybridizes with the latter species. Hartwich describes the microscopical characteristics of Cinchona and related barks in *S. W. P.*, 1909, p. 249. Grutterink discusses the microchemistry of Cinchona alkaloids, with illustrations in *Zeit. anal. Chem.*, 1912, p. 215. Rosenthaler reviews the pyro-analytical results that have been obtained with Cinchona Bark and describes the crystals found in the tar. (*B. P. G.*, 1911, p. 203.)

The quills of *Red Bark* are similar to those of Calisaya, though running somewhat broader and thicker. Externally of a dingy brown gray, less lichen-bearing than either of the others. Inner surface of a more reddish cinnamon-brown than in calisaya. Powder reddish-brown. The important characteristic of red bark is the prominent longitudinal ridges, many of them short and confluent, with intervening furrows or elongated meshes. The ridges are suberous, bear numerous small warty protuberances, and may be traversed by faint fissures. Transverse fissures may or may not be present in Red Bark. If so, they are few, short, and irregularly disposed, and not connected by longitudinal cracks to give the checkered appearance of Calisaya. Hybrids with "officinalis" display numerous transverse fissures, and the external color is lighter and more dingy. Fracture short-splintery, not coarse. Odor none. Taste bitter and astringent.

It is scarcely collected in a wild state, but cultivated in all plantations except those of South America. Demand and production are rapidly decreasing. A large alkaloid yielder, but of this only about 20 per cent. is quinine. Largely hybridized with *C. officinalis*. Also hybridized with *C. Calisaya* and its var. *Ledgeriana*.

Under the titles of *Pale Bark, Crown Bark, Loxa* or *Loja Bark, Cuenca Bark, Huanuco Bark,* the bark of *C. officinalis,* while not official, is important as a source of quinine. It occurs above Loxa and other parts of Ecuador, and is cultivated in all plantations except the South American, especially in India. Quinine constitutes 60 to 70 per cent. of the total alkaloids. Largely hybridized with *C. succirubra.*

The quills of Pale Bark are single or double, irregularly broken or entire, attaining a length of nearly 2 dm., a width of nearly 2.5 cm., and having a very wide range in thickness, the natural mostly 2 to 4 mm. thick. Shaggy, with more abundant lichens than in any other species, the abundance of these having been considered, not entirely without reason, as an indication of the relative quality. Color of periderm darker than in the other species, but varying much from a brown gray to nearly black. Inner surface of a paler brown than in the other species, finely striate. Color of powder pale brown. The external markings consist of transverse fissures and longitudinal ridges, some of them wart-bearing. It is only in the thinner samples, in which the warts and fissures scarcely appear, that the ridges are continuous and conspicuous. In the prominence and breadth of its fissures and the inconspicuousness of its ridges, this bark is most distinct from the Red Bark. These characters are yet sufficiently distinct from the somewhat similar ones of Calisaya, as noted in describing that bark. Fracture short, the inner fibrous zone sharp and narrow. Taste not so bitter as in the others. Odor of the genuine Loxa variety peculiar and characteristic. Its structure shows the rather short and not numerous bast fibers in short interrupted single or double radial rows, and much disposed to occur in bundles of three to six or more. Stone cells rarely seen, and laticiferous ducts conspicuous only when young.

Description of various other species as the *C. Pelletierana* (*Cusco Bark*), the *C. cordifolia* (*Maracaibo Bark*), the *C. lancifolia* Mutis (*Cartagena Bark*) which were at one time of some commercial importance but have entirely disappeared from our markets can be found in the *U. S. D.*, 16th edition.

Constituents.—Deschamps, an apothecary of Lyons, obtained from the bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid* (*quinic acid*). The latter chemist also arrived at the conclusion that those barks were most efficient which gave precipitates with tannin or the infusion of galls. Ruess, of Moscow, succeeded in isolating a peculiar coloring matter from red bark, which he designated by the name of *cinchonic red,* and obtained a bitter substance which probably consisted in part of the peculiar alkaline principles subsequently discovered. The first step, however, towards the discovery of the true active principle appears to have been taken by Duncan of Edinburgh, so early as 1803. He believed the precipitate afforded by the infusion of cinchona with that of galls to be a peculiar vegetable principle, and accordingly denominated it *cinchonin.* Gomez (1816), a Portuguese physician, obtained, by the action of potassium hydroxide upon an aqueous infusion of the alcoholic extract of the bark, what he believed to be a pure form of the same principle found by Duncan and which was probably the principle now known by the name of *cinchonine.* But Gomez was ignorant of its precise nature, considering it to be analogous to resin. To Pelletier and Caventou was reserved the honor of crowning all these experiments, and applying the results which they obtained to important practical purposes. In 1820 they demonstrated the alkaline character of the principle discovered by Gomez, and gave it definitively the name of *cinchonine.* They discovered in the yellow or Calisaya bark another alkaline principle, which they denominated *quinine.* Both these bases they proved to exist in the bark, combined with *quinic* or *kinic acid.* It was, moreover, established by their labors that the febrifuge property of bark depends upon the presence of these two principles.

Subsequent investigators have isolated some twenty or more alkaloids from various species of cinchona. Of these, four—quinine, quinidine, cinchonine and cinchonidine—afford salts which are officially recognized and are discussed under their respective titles. The others are briefly described immediately below. Wherry and Yanobsky (*J. Am. C. S.,* 1918, xl, 1063) have studied the refractive indices, optical activities and crystal measurements of quinine, cinchonine, quinidine and cinchonidine and demonstrate the possibility of detecting any of these alkoloids in a mixture.

In a very careful series of experiments made at the Java governmental cinchona plantations, Lotsy (*Bull. Inst. Botanique Buitenzorg,* 3, 1900) found that the seeds of *C. succirubra* and *C. Ledgeriana* contain no alkaloids, but that these alkaloids appear in the cotyledons shortly after they become green. They exist chiefly in the bark in combination with a tannic acid. Lotsy found that the percentage of alkaloids is ten times greater in young than in old leaves; also that the petioles are richer in alkaloids than is the blade, and that the branch bark contains more than the trunk bark, and that the root bark is practically free from alkaloids. During the active life of the parenchymatous cells of the leaves, wood, and cortex, the alkaloids can always be found in the active protoplasmic contents, but when these cells pass into the inactive condition, are deposited in the cell-walls. The alkaloids found in the leaves are, however, never crystalline, hence it would appear that these organs produce by direct synthesis, probably as the result of the action of cinchonic acid with ammonia, a fundamental alkaloidal base, which, probably in the cambium layer of the tree during its deposition in the growing bark, is elaborated into the true cinchona alkaloids.

The total amount of alkaloids, as well as the relative proportions of different ones, varies greatly in individual samples of bark. In a general way it may be said that the Red Bark contains from 5 to 7 per cent. (occasionally more) of which about one-fifth two two-fifths is quinine; Calisaya runs about 6 to 8 per cent. of which approximately one-half is quinine; Ledger Bark averages from 6 to 10 per cent. with usually three-fourths of this quinine. The richest specimen of which we know was a sample of Ledger containing 14.5 per cent. of alkaloids. Generally speaking, the root barks contain more than the stem barks.

Under the name of *quinetum* or *febrifuge* a compound is produced in India and other Eastern countries, which consists of the mixed alkaloids of Red Bark, the object being to produce a cheap febrifuge which will answer all practical purposes and save the cost of refining. It is largely produced at Sikkim, India, by a modification of Dubreuil's process, which consists in extracting the powdered mixed barks with hydrochloric acid, precipitating the alkaloids by the addition of solution of sodium hydroxide, and shaking out with petroleum, adding to the petroleum solution a calculated quantity of diluted sulphuric acid, evaporating and crystallizing.

Besides the natural bases we have a number of alkaloids formed by the alteration or treatment of these natural bases, or in some cases molecular compounds of two of the natural bases.

Chinoidine or *Quinoidine* is a term now applied to the resinous substance consisting not only of the *amorphous* natural alkaloids, but of those which are produced artificially through the action of the heat and acids upon the crystalline alkaloids. (See Part II.)

The following list of bases from Cinchona or allied sources is arranged alphabetically.

ARICINE or *quinovatine,* $C_{23}H_{26}O_4N_2$, found in the *C. cordifolia* var. *Pelletieriana,* melting point 188° C., optical rotation —58° 18′ (see Hesse, *Ann. Chem.,* 1873, clxvi, 1877, clxxxv; Moissan and Landrin, *Bull. Soc. Chim.,* 1890, iv).

CINCHOTINE, $C_{19}H_{24}ON_2$, also known as *hydrocinchonine* and *cinchonifine,* found in many species of cinchona, usually a constituent of commercial cinchonine and also prepared by the catalytic hydrogenation of cinchonine. (Heidelberger and Jacobs, *J. Am. C. S.,* 1919, xli.) Crystallizes in prisms, melting point of 268° to 269° C. Optical rotation + 204.5, in alcohol, is diacidic.

CUSCONINE and *concusconine,* isomeric with aricine, like it occur in the cusco bark. This bark also contains, according to Hesse (*Ann. Chem.,* 1880, cc), *cuscamine, cuscamidine* and *cusconidine,* the composition of which are unknown.

DICINCHONINE, $C_{38}H_{44}O_2N_4$ found in the *C. rosulenta* and *C. succirubra,* also known as *dicinchonicine* and as *apodicinchonine.* It is amorphous and dextrorotary (Hesse, *Ann. Chem.,* 1885, ccxxvii).

DICONQUININE, $C_{40}H_{46}O_4N_4$, also known as *diquinicine* or *apodiquinidine,* forms the chief ingredient of the mixture known commercially as *quinoidine.* It is amorphous and dextrorotary. (Hesse, *B. Chem. G.,* 1877, x.)

HOMOCINCHONIDINE, $C_{19}H_{22}ON_2$, isomeric with cinchonidine, occurs in several barks but especially in the *C. rosulenta.* It is also produced by the action of hydrochloric acid on cinchonidine. It does not give the thalleioquin reaction. Its physical constants are so close to those of cinchonidine that its separate identity has been denied.

HYDROCINCHONIDINE, $C_{19}H_{24}ON_2$, also known as *cinchamidine,* first isolated by Forst and Börhinger (*B. Chem. G.,* 1881, xiv) from *C. Ledgeriana,* but also occurs in other species. Is best prepared by hydrogenation of cinchonidine. Its crystals have a melting point of 229° C. and an optical rotation of -98.4 in alcohol, the salts exhibit no fluorescence nor thalleioquin reaction (Heidelberger and Jacobs, *J. Am. Chem. S.,* 1919, xli).

HYDROQUINIDINE (*hydroconquinine*), $C_{20}H_{26}O_2N_2 + 2\frac{1}{2}H_2O$, is found in commercial quinidine and may be separated by potassium permanganate treatment. It is crystalline, dissolving freely in hot alcohol and in chloroform, but less freely in ether. It gives the thalleioquin reaction like quinine. (Forst and Böhringer, *B. Chem. G.,* 1882, xv; Heidelberger and Jacobs, *J. Am. C. S.,* 1919, xli.)

HYDROQUININE (*methyl-hydrocupreine*), $C_{20}H_{26}O_2N_2$, was discovered by Hesse in the mother liquors from *C. Ledgeriana* after quinine sulphate has been crystallized (*B. Chem. G.,* 1882, xv). It is a frequent constituent of the commercial quinine sulphate. Its crystals melt at 172.3° C. and show an optical rotation of -142.2 in alcohol. It shows the thalleioquin reaction and is a diacidic base. Quinine cannot be perfectly freed from hydroquinine even by repeated crystallization of the neutral sulphates, but the hydroquinine can be completely separated by converting the alkaloid into the acid sulphate and recrystallizing this from water or alcohol, when the hydroquinine remains in the mother liquor. (Allen.) The hydrochloride, $C_{20}H_{26}O_2N_2HCl.2H_2O$, forms crystals which are readily soluble in water and alcohol. Morganroth and Hallberstadter (*B. K. W.,* 1911) assert that this agent will cause a disappearance of trypanosomes from infected animals, which quinine will not do. Giemsa and Werner (*Cb. G. T.,* 1912, p. 492) assert that *hydroquinine* is more efficacious in *malaria* than quinine. It has also been commended by Lenzmann (*M. M. W.,* 1912, p. 2193) as a local application in *whooping cough.* The *dose* used by Giemsa and Werner was three grains (0.2 Gm.) three or four times a day. It is of commercial importance as a material for the manufacture of *hydrocupreine* (see *Optochine,* Part II).

JAVANINE.—Found in the *C. Calisaya* var. *Javanica,* composition unknown. (Hesse, *B. Chem. G.,* 1877, x.)

PARICINE, $C_{16}H_{18}ON_2$, optically inactive, melting point 130°, forms amorphous salts, found in the *C. succirubra.* (Hesse, *Ann. Chem.,* 1873, clxvi.)

QUINAMIDINE (*Conquinamine* of Hesse), $C_{19}H_{24}O_2N_2$, is found in *C. rosulenta* and *C succirubra,* and probably exists in other species of Red Bark. It crystallizes in long, brilliant prisms, which melt at 123° C. It may be formed in acid solutions of quinamine through decomposition. (Hesse, *Ann. Chem.,* 1881, ccix.)

QUINAMINE, *Quinamia,* $C_{19}H_{24}O_2N_2$.—Hesse discovered this cinchona alkaloid in the bark of *C. succirubra.* He has since found it in several other species, and particularly *C. Ledgeriana.* Melting point 172° C.; optical activity, $+104.5$ in alcohol. Quinamine is almost tasteless, but its solutions in acids are very bitter. Its sulphuric acid solution is not fluorescent.

QUINICINE, $C_{20}H_{24}O_2N_2$, was first formed by Pasteur, 1853, by heating quinine bisulphate and subsequently by Hesse in a similar manner from quinidine; the latter named it *quinotoxine.* It also occurs naturally in cinchona bark. (Howard and Chick, *J. P.,* 1917, xcix, p. 143.)

Besides the genus *Cinchona* certain of the allied genus *Remijia* contain quinine or related alkaloids and have been used in medicine. Of these the *R. pedunculata* Triana (*Cinchona pedunculata* Karsten) formerly appeared in commerce under the name of *cuprea bark* and the *R. Purdieana* Weddell as *false cuprea.* In these barks are found the following alkaloids in addition to some of those which occur in the cinchona barks.

CINCHONAMINE, isomeric with cinchotine, occurs in the *R. Purdieana.* It is said to be a more potent antipyretic than quinine and also poisonous. Melting point 194° C., optical rotation, $+121.1$ in alcohol. It does not respond to the thalleioquin test. See Howard (*J. Soc. Chem. Ind.,* 1905, xxiv, 1909, xxviii.) Physiologically, cinchonamine, according to the experiments of Sée and Bochefontaine, has six times the toxic power of quinine, and has decided sialagogue properties. (*P. J.,* 1885, p. 761.)

CHAIRAMINE and *Chairamidine, Conchairamine* and *Conchairamidine;* these isomers have the formula $C_{22}H_{26}O_4N_2$ and are found in the *R. Purdieana.* For method of separating them see Hesse (*Ann. Chem.,* 1884, ccxxv, p. 211).

CUPREINE.—This is the chief alkaloid of the *R. pedunculata.* The anhydrous crystals melt at 198° C. and have an optical activity of -175.5 in dehydrated alcohol. It gives the thalleioquin reaction. The substance known as *homoquinine* is probably a molecular combination of quinine and cupreine. The anhydrous crystals melt at 177° C. Cupreine is a diacidic base which on methylation is converted into quinine. (Howard, *Tr. Chem. Soc.,* 1882, xli; *J. Soc. Chem. Ind.,* 1909, xxviii; Paul and Cownley, *P. J.,* 1881, xii, 1884, xv.)

In addition to the numerous alkaloids, several other more or less interesting substances have been found in cinchona barks. The most important of these are as follows:

TSCHIRCHIN is a green coloring matter, not identical with chlorophyll, which has been extracted from *Cinchona Succirubra* by Glücksmann.

Cinchocerotin, $C_{27}H_{48}O_2$.—This substance was discovered by Kerner in flat Calisaya bark from South America. He obtained it in white, very light, crystalline scales. It is not soluble in boiling water, nor in hydrochloric, diluted sulphuric, or glacial acetic acid, but dissolves readily in ether, chloroform, and alcohol. (See Helms, *A. J. P.*, 1883, p. 357.)

Cinchofulvic Acid.—The *cinchonic red* of Reuss, identical with the *insoluble red coloring matter* of Pelletier and Caventou, $C_{12}H_{14}O_7$, is reddish brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but if treated with a cold solution of potassium or sodium hydroxide, or with ammonia, lime, or baryta with heat, and then precipitated by an acid, it acquires the property of forming an insoluble compound with gelatin. It yields protocatechuic acid, $C_7H_6O_4$, when fused with potassium hydroxide. It is most abundant in the red bark (over 10 per cent.), and least so in the pale.

Cinchotannic Acid. *Cinchotannin*, $C_{14}H_{16}O_9$.—Is present as a glucoside in cinchona barks in the proportion of 3 to 4 per cent. It has a brownish-red color and an austere taste, is soluble in water and alcohol, and produces precipitates with the salts of iron, which vary in color according to the variety of bark, being deep green with the pale bark, blackish-brown with the yellow, and reddish-brown with the red. Rembold has shown that when cinchotannic acid is boiled with diluted sulphuric acid, cinchonic red is produced, sugar being formed at the same time.

Quinic Acid (*Hexahydrotetraoxybenzoic Acid*), $C_7H_{12}O_6$.—This acid was isolated as early as 1790 by Hofmann, an apothecary of Leer, who obtained it from the calcium salt from cinchona. It exists in a number of important plants—ivy, oak, elm, ash, coffee, etc. It is usually prepared from calcium quinate, the residue obtained in the manufacture of quinine sulphate (see *Quininæ Sulphas*) by decomposing an aqueous solution of calcium quinate with oxalic acid, filtering out the precipitated calcium oxalate, and evaporating the filtrate to the crystallizing point. The crystals are transparent and colorless, sour to the taste, soluble in 2 parts of water, but less soluble in alcohol, and almost insoluble in ether. By heating quinic acid or a quinate with manganese dioxide and sulphuric acid, we get yellow crystals of *kinone*, better known as *quinone*, $C_6H_4O_2$, a reaction which may be used for ascertaining the presence of quinic acid. It is non-toxic and seems, like other vegetable acids, to be decomposed in the system, forming, when taken in the state of an alkaline salt, a carbonate of the alkali in the blood, and rendering that fluid alkaline. Several esters of quinic acid and compounds with synthetic bases have been introduced into medicine, viz.—*chinotropin, sidonal, new sidonal, urosin,* and *ural.* (See Part II.)

Quinovin, *Kinovin,* or *Chinovin,* $C_{38}H_{62}O_{11}$.—This bitter glucoside probably exists, in greater or less proportion, in all the Cinchona barks. It is white, uncrystallizable, almost insoluble in water, but readily dissolved by alcohol and ether. Winckler gives, as a certain test of its presence in any bark, copper sulphate, which indifferent to infusion of bark containing none of this principle, produces a dirty-green color, soon followed by the deposition of a fine similarly colored powder. This salt of copper, has a bitter and metallic taste. (See *A. J. P.*, xxv, 343.) Quinovin in alcoholic solution under the influence of hydrochloric acid hydrolyzes into *quinovic acid,* $C_{24}H_{38}O_4$, and an uncrystallizable sugar, *mannitan,* $C_6H_{12}O_5$, by assimilation of H_2O.

Liebermann and Giesel (*B. Chem. G.*, xvi, 987) believe that two modifications exist, *α-quinovin* and *β-quinovin,* the former in Cinchona, the latter in Cuprea bark: α-quinovin is a white crystalline powder, nearly insoluble in cold and hot water, but soluble in caustic alkalies, lime water, ammonia water, and glacial acetic acid, soluble with difficulty in chloroform, ether, and petroleum benzin; it dissolves in 57 parts of nearly absolute alcohol. β-quinovin closely resembles α-quinovin, but is not soluble in ether, and crystallizes readily from diluted alcohol.

Quinovic Acid (*Kinovic Acid*), $C_{32}H_{48}O_6$, occurs as white, rhomboidal crystals, insoluble in water, slightly soluble in ether or alcohol, but very soluble in ammonia and the fixed alkalies, the solutions frothing like soap water. On adding an acid to an alkaline solution of quinovic acid, a hydrate of quinovic acid is thrown down as a very voluminous jelly, the whole contents of the vessel gelatinizing.

The odor of bark appears to depend on a *volatile oil,* which Fabroni and Trommsdorff obtained by distillation with water. The oil floated on the surface of the water, was of a thick consistence, and had a bitterish, acrid taste, with the odor of bark.

Scoville (*J. A. Ph. A.*, 1921, x, 844) has reported on experiments in the extraction of cinchona, from which he concludes that hydrochloric acid is of material aid both in extraction of the alkaloids and in reducing precipitaton from the fluidextract. He recommends as the most favorable proportion a menstruum containing 1.6 per cent. of the acid. The complete extraction is slow and tedious and necessitates the use of a large quantity of menstruum.

Assay.—The U. S. assay for cinchona is as follows: "Heat 5 Gm. of Cinchona, in fine powder, for one hour, in a 500 cc. flask on a water bath, with 5 cc. of diluted hydrochloric acid and 10 cc. of distilled water. Cool, add 200 cc. of ether-chloroform mixture, and 10 cc.

of strong ammonia T.S. Proceed by Type Process A, decanting an aliquot portion of 160 cc., representing 4 Gm. of Cinchona, and determine the alkaloids gravimetrically. Use chloroform for the final extraction (Proximate Assays)." *U. S.*

The British directions are as follows:

Test.—"Red Cinchona Bark when used for official purposes other than the preparation of alkaloids or their salts, is required to yield from 5 to 6 per cent. of total alkaloids, of which not less than one-half consists of quinine and cinchonidine, as determined by the following process: Mix 10 grammes of Red Cinchona Bark, in No. 60 powder, with 6 grammes of *calcium hydroxide;* add 22 millilitres of *water,* mix intimately in a small porcelain dish or mortar, and set aside for an hour or two. Transfer this mixture to a suitable flask fitted with a reflux condenser, add 130 millilitres of *benzolated amylic alcohol,* boil for about half an hour, and then decant the liquid on to a filter, leaving the sediment in the flask; add more of the *benzolated amylic alcohol* to the sediment, and boil and decant as before; repeat this operation a third time; then transfer the contents of the flask to the filter, and wash by percolation with more of the *benzolated amylic alcohol* until the Bark is exhausted. Introduce the collected filtrate, while still warm, into a stoppered glass separator; add to it 2 millilitres of *diluted hydrochloric acid,* mixed with 12 millilitres of *water;* shake well together, and allow the liquids to separate; draw off the acid liquid, and repeat the process with *water* slightly acidified with *hydrochloric acid,* until the alkaloids have been completely removed. Carefully and exactly neutralise the acid liquid, while warm, with *solution of ammonia,* and concentrate by evaporation to the bulk of 16 millilitres. To the concentrated solution add about 1.5 grammes of *sodium potassium tartrate,* dissolved in twice its weight of *water,* stirring with a glass rod; after about one hour collect the precipitate, wash dry at 100° C. and weigh; the weight in grammes multiplied by 8 gives the percentage of quinine and cinchonidine in the Bark. To the mother-liquor and washings from the preceding process add *solution of ammonia* in slight excess and shake with three successive portions of 10 millilitres of *chloroform;* evaporate the mixed chloroformic solutions to dryness, dry the residue at 110° C and weigh. The weight in grammes multiplied by 10 and added to the percentage of the quinine and cinchonidine, gives the percentage of total alkaloids." *Br.*

The German Pharmacopœia gives the following method: "The powdered bark is assayed as follows: Shake 20 Gm. of it strongly and repeatedly with a mixture of 10 Gm. of water of ammonia, 20 Gm. of alcohol, and 170 Gm. of ether, and, after a day, decant 120 Gm. of the clear liquid. To this liquid add 3 cc. of volumetric hydrochloric acid, remove the ether by distillation or evaporation, and again add, if necessary, enough hydrochloric acid to render the solution acid. Then filter, and mix the cold filtrate with 3.5 cc. of volumetric solution of potassa. When the alkaloids have subsided, drop more of the solution of potassa into the clear supernatant liquid, until nothing more is thrown down. Finally, collect the whole of the precipitate on a filter, and wash it repeatedly with small portions of water, until drops of the wash water allowed to come in contact with the surface of a cold, aqueous, neutral, saturated solution of sulphate of quinine no longer produce a turbidity. When the alkaloids have drained, press them gently between bibulous paper, and, having dried them sufficiently in the air to permit their being removed to a watch-glass, dry them completely, first over sulphuric acid, and, finally, by means of a water-bath. The weight of alkaloids procured by this method should not be less than 0.42 Gm. When a small portion of the same is boiled with 300 parts of water, the filtrate, after cooling, should yield flakes of quinine. When to 5 parts of this solution, after being cooled and decanted, 1 part of chlorine water is added, and water of ammonia immediately dropped in, the liquid should acquire a beautiful green color." For E. R. Squibb's method of assay, see *U. S. D.,* 18th ed., p. 412.

It is sometimes desirable to ascertain not only the quantity of total alkaloids but also the proportion of quinine. For the latter purpose the total alkaloids extracted by the U. S P. method may be exactly neutralized N/10 sulphuric acid, the resulting liquid then diluted with sufficient water that it contains one part of total alkaloid in 70 parts of solution by weight. This is then heated to 90° for 5 minutes and cooled to 15° and set aside at this temperature for 30 minutes when crystals of quinine sulphate will separate out. These crystals are collected on a tared filter and washed with water at 15° until the filtrate weighs 90 Gm. for each Gm. of total alkaloid taken, then dried and weighed. A correction representing the solubility of quinine sulphate in water at 15° is required and for this purpose 0.00817 Gm. should be added for each gramme of filtrate and washings. The sum divided by 0.855 gives the yield of crystallized quinine sulphate (Henry, *Plant Alkaloids,* 1924). For another method of separating the cinchona bases see Leger (*J. P. C.,* 1904, xix, 427).

Uses.—When taken into the stomach, the bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state; and its action is not unfrequently accompanied by purging. If the dose of the cinchona bark has been large enough, the symptoms of cinchonism may result. (See *Quinina.*) At one time cinchona bark and its preparations were used as antiperiodics, but at present for such purpose one or another of its alkaloids is always selected. MacGilchrist (*Indian Journ. Med. Res.,* 1915, iii, p. 1) arranges the chief alkaloids in the following order of efficacy in malarial fevers: hydroquinine, cinchonine, quinine, quinidine, optochin, cinchonidine, and quinoidine. The best preparation for use as a tonic is the compound tincture.

Dose, ten grains to one drachm (0.65–3.9 Gm.).

CINCHONIDINÆ SULPHAS. U. S.

CINCHONIDINE SULPHATE Cinchonid. Sulph.

"The sulphate [$(C_{19}H_{22}ON_2)_2H_2SO_4.3H_2O$] of an alkaloid obtained from cinchona bark." *U. S.*

Cinchonidinum Subsulfuricum; Sulphate of Cinchonidine; Schwefelsaures Cinchonidin, Cinchonidinsulfat, *G.;* Sulfate de Cinchonidine basique, *Fr.;* Solfato di cinconidina, *It.*

This salt is prepared from the mother liquors obtained in the manufacture of quinine sulphate, and is separated from the sulphates of the other alkaloids by fractional crystallization.

Owing to some confusion in naming cinchonidine and quinidine, this alkaloid is sometimes incorrectly called in Germany *chinidine.* Skraup's researches on the composition of cinchonine and cinchonidine (1879) established the correctness of the formula $C_{19}H_{22}ON_2$, instead of the long-accepted formula of Pasteur (1853), $C_{20}H_{24}ON_2$. Skraup's formula has been confirmed by Hesse, and is generally accepted by chemists.

Basic *cinchonidine* is not official. It crystallizes in large trimetric prisms with a melting point of 207.2° C. (Lenz), or 202.4° C. (Hesse), and an optical activity of -111 in alcohol. It is practically insoluble in cold water, soluble in about 20 parts of alcohol, requires about a thousand parts of dry ether to dissolve it but is somewhat more soluble in the official ether.

Cinchonidine is found in most varieties of cinchona bark, but is especially abundant in the *C. succirubra.* It is a diacidic base and may be readily distinguished from quinine and quinidine by the absence of fluorescence in the solutions of its salt and by not giving the thalleioquin reaction.

Description and Physical Properties.—"White, glistening, silky needles or prisms. It is odorless, and has a very bitter taste. One Gm. of Cinchonidine Sulphate is soluble in 65 cc. of water, 90 cc. of alcohol, and in 620 cc. of chloroform, at 25° C. One Gm. is soluble in 22 cc. of water at 80° C. and in 41 cc. of alcohol at 60° C. It is nearly insoluble in ether.

"An aqueous solution of Cinchonidine Sulphate is lævorotatory. The addition of ammonia T.S. to an aqueous solution of Cinchonidine Sulphate (1 in 100) produces a white precipitate of cinchonidine, which is but slightly soluble in ammonia T.S. or in ether. Sodium tartrate T.S. produces in an aqueous solution (1 in 100) a white precipitate of cinchonidine tartrate (*difference from cinchonine*). An aqueous solution of Cinchonidine Sulphate yields with barium chloride T.S. a white precipitate, insoluble in hydrochloric acid.

"A saturated aqueous solution of Cinchonidine Sulphate is neutral or faintly alkaline to litmus paper. Dried to constant weight at 100° C., Cinchonidine Sulphate loses not more than 12 per cent. (*water*). Ash: not more than 0.1 per cent. A solution of 0.1 Gm. of Cinchonidine Sulphate in 2 cc. of sulphuric acid is not darker than faint yellow (*readily carbonizable substances*). A 10 cc. portion of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a faint, blue fluorescence (*quinine or quinidine*). Macerate 0.5 Gm. of Cinchonidine Sulphate, with frequent agitation, at room temperature, with 20 cc. of distilled water, then add 0.5 Gm. of potassium and sodium tartrate, and continue the maceration with repeated agitation for one hour at 15° C., and filter the mixture. The addition of 1 drop of ammonia T.S. to the filtrate produces not more than a slight turbidity (*cinchonine or quinidine sulphate*).

"Preserve in well-closed containers, protected from light." *U. S.*

The *acid sulphate* (sometimes called *bisulphate*) is much more soluble in water than the official sulphate. *Cinchonidine salicylate* is neutral and crystalline, insoluble in cold water, sparingly in hot water, easily soluble in alcohol and diluted alcohol. It may be prepared by the direct combination of salicylic acid with the alkaloid. The *hydrobromide* has been employed by Gubler hypodermically. Königs and Husmann having claimed to have converted cinchonine into cinchonidine by the long-continued action of boiling amyl alcohol and solution of potassium hydroxide, Paul and Cownley have investigated this treatment. They failed to get such conversion, and consider that the cinchonine used by Königs and Husmann must have been impure. (*P. J.,* Feb. 20, 1897.)

Uses.—So far as our knowledge goes, this alkaloid influences the system similarly to quinine, the only difference being that it is less powerful. It may be given in doses one-third greater than those of quinine, but should not be relied on in severe cases.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Elixir Cinchonæ Alkaloidorum and in other Elixirs containing Cinchona Alkaloids in combination with Iron, Bismuth, etc., *N. F.*

CINCHONINÆ SULPHAS. N. F.

CINCHONINE SULPHATE Cinchonin. Sulph.

"The sulphate [$(C_{19}H_{22}ON_2)_2.H_2SO_4.2H_2O =$ 722.68] of an alkaloid obtained from the bark of several species of cinchona." *N. F.*

Cinchoniæ Sulphas, *U. S.* 1870; Sulfate de Cinchonine basique, *Fr.* Schwefelsaures Cinchonin, Cinchoninum Sulfuricum, Cinchoninsulfat, *G.;* Solfato Cinchonico, *It.;* Sulfato de cinconina, *Sp.*

Cinchonine is present in nearly all species of cinchona bark; it is especially evident in the *C. micrantha.* Commercially it is obtained from the mother liquors after separation of quinine. The addition of sodium hydroxide to this liquor causes the precipitation of the remaining alkaloids, chiefly quinidine, cinchonidine and cinchonine. Because of the sparing solubility of cinchonine in ether, this precipitate is first shaken out with ether to remove the two other alkaloids, and the insoluble residue extracted with successive portions of boiling alcohol from which the cinchonine crystallizes out on cooling.

Its formula is now generally accepted as $C_{19}H_{22}ON_2$, the molecular weight of which is 292.03. It is, therefore, isomeric with cinchonidine. The base occurs in "white, lustrous prisms or needles, without odor, at first almost tasteless, but soon developing a bitter aftertaste; permanent in the air. Soluble, at 15° C., in 3760 parts of water, and in 116 parts of alcohol; in 3500 parts of boiling water, and in 26.5 parts of boiling alcohol. Also soluble in 526 parts of ether, and in 163 parts of chloroform. At 240° C. the crystals fuse together, and at 258° C. they melt, forming a brown liquid. When ignited, they are consumed without leaving a residue." *U. S.,* 1890. The optical rotation is $+229°$ C. in dry alcohol. It is a strongly alkaline, diacidic base, forming two series of salts, neutral and acid.

It differs from quinine by its rotating the plane of polarization to the right, by the want of fluorescence in its solutions, and by its failing to respond to the thalleioquin test. Chlorine water dissolves it or any of its salts without change; but if ammonia be now added, a white precipitate is produced. It is thus distinguishable from quinine. (See *Quinina.*) J. W. Bill, proposed potassium ferrocyanide as a very delicate test of cinchonine. If added to the solution of a salt of this alkaloid, it produces a yellowish-white curdy precipitate, which is dissolved upon the application of a gentle heat, but is again deposited, when the liquid cools, as an abundant crop of golden-yellow crystals. No other alkaloid exhibits the same reaction. A cloudy precipitate is produced by the same reagent with a salt of quinine; but this does not happen when the ferro-cyanide is in excess; and, if the precipitate be dissolved by heat, no subsidence takes place on cooling. Hence, in the application of this test to cinchonine, a slight excess of the ferrocyanide should be added.

The substance known as *homocinchonine* is an impure form of cinchonine.

There are two cinchonine sulphates, the neutral and the acid sulphate. The official salt is the neutral sulphate.

Description and Physical Properties.—"Cinchonine Sulphate occurs as white, lustrous prismatic crystals; odorless and having a very bitter taste; permanent in the air. One Gm. of Cinchonine Sulphate dissolves in 60 cc. of water, 12.5 cc. of alcohol, 47 cc. of chloroform, and in 3230 cc., of ether at 25° C.; also in 33 cc. of water at 80° C. and in 7 cc. of alcohol at 60° C.

"A saturated aqueous solution of the salt is neutral or slightly alkaline to litmus and is dextrorotatory. An aqueous solution of Cinchonine Sulphate (1 in 100) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. Dried to constant weight at 100° C. Cinchonine Sulphate loses not more than 5 per cent. of its weight.

"Incinerate about 1 Gm. of Cinchonine Sulphate; not more than 0.1 per cent. of ash remains. Ten cc. of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a slight, blue fluorescene. One-tenth Gm. of the powdered salt dissolves completely or nearly so, when shaken with 10 cc. of chloroform at ordinary temperatures (*quinine* or *cinchonidine sulphate*). Add 0.1 Gm. of the salt to 2 cc. of sulphuric acid; it imparts not more than a faint yellow tinge to the acid (*readily carbonizable, organic impurities*)." *N. F.*

The *acid sulphate,* or *bisulphate,* $C_{19}H_{22}ON_2.H_2SO_4.3H_2O$, is prepared by adding sulphuric acid to the neutral sulphate. According to Baup, 100 parts are soluble in 45 parts of absolute alcohol; it is insoluble in ether. It crystallizes in rhombic octahedrons.

Uses.—Cinchonine undoubtedly possesses in marked degree the anti-malarial properties of quinine; indeed, MacGilchrist reaches the conclusion that the two alkaloids are of approximately equal powers but is inclined to the view that cinchonine is slightly superior. Rogers (*B. M. J.,* 1918, ii, 459) used a bi-hydrochloride of cinchonine by intramuscular injection with very satisfactory results in all forms of *malaria,* especially in the malignant tertian variety, he found experimentally that this salt was absorbed much more rapidly than the corresponding salt of quinine. As to whether it possesses the other therapeutic properties of quinine, we have no definite information.

Dose, tonic, a grain or two (0.065–0.13 Gm.) three or four times a day; antiperiodic dose, fifteen to forty grains (1.0–2.6 Gm.) between the paroxysms.

Off. Prep.—Elixir Cinchonæ Alkaloidorum and in other Elixirs containing Cinchona Alkaloids in combination with iron, bismuth, etc., *N. F.*

CINCHOPHENUM.

CINCHOPHEN Cinchophen. [Acidum Phenylcinchoninicum, U. S. P. IX, Phenyl-quinoline carboxylic Acid]

"Cinchophen, when dried to constant weight over sulphuric acid, contains not less than 99 per cent. of $C_6H_5.C_9H_5N.COOH$." *U. S.*

Cinchophen, Atophan, Phenylcinchoninic Acid.

Phenylcinchoninic acid is produced by a complicated process of manufacture in which pyruvic acid (prepared by the distillation of tartaric acid) is first heated with benzaldehyde, in molecular proportions, and a solution of one molecular equivalent of aniline in absolute alcohol then added. The reaction is completed by boiling under a reflux condenser for three hours. Upon cooling, crystals of the crude product separate. These may be purified by reprecipitation and recrystallization.

In another process, isatin, acetophenone, alcohol and an alkali are used in the initial stages.

For description of related compounds, see *Cinchophen Derivatives,* Part II.

Description and Physical Properties.—"Small, colorless, needle-like crystals, or a white to yellowish-white powder. It is odorless, has a slightly bitter taste, and is stable in the air. Cinchophen is almost insoluble in cold water. One Gm. is soluble in about 400 cc. of chloroform, 100 cc. of ether, and in 120 cc. of alcohol, at 25° C. It is more readily soluble in hot than in cold alcohol.

"Cinchophen melts at about 210° C. with partial decomposition. A saturated solution of Cinchophen in hot diluted hydrochloric acid yields with platinic chloride T.S. a precipitate of yellowish-brown crystals. Dissolve about 1 Gm. of Cinchophen in an excess of ammonia T.S., evaporate the solution to dryness on a water bath, or until free from the odor of ammonia, dilute to 20 cc. with distilled water, and filter: portions of the filtrate yield a white, flocculent precipitate with silver nitrate T.S., a yellowish, flocculent precipitate with lead acetate T.S., and a green, flocculent precipitate with copper sulphate T.S. The ash from 0.2 Gm. is negligible. A solution of 0.1 Gm. of Cinchophen in 5 cc. of sulphuric acid is not darker than yellow (*readily carbonizable substances*). On adding three drops of nitric acid to this solution, no reddish or brown color is produced.

"**Assay.**—Weigh accurately about 0.5 Gm. of Cinchophen, previously dried to constant weight over sulphuric acid, and dissolve it in 60 cc. of alcohol which has been neutralized with tenth-normal sodium hydroxide, using three drops of phenolphthalein T.S. as indicator, and warming gently to facilitate solution. Cool, and titrate the solution with tenth-normal sodium hydroxide until the pink color is restored. Each cc. of tenth-normal sodium hydroxide corresponds to 0.02492 Gm. of $C_6H_5.C_9H_5N.COOH$.

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—In 1908 Nicolaier and Dohrn (*D. K. M.,* 1908, xciii) showed that phenylcinchoninic acid caused an extraordinary increase in the excretion of uric acid; as this excretion was increased in persons upon a purin-free diet, they believed that it was due to increased output of the endogenous uric acid. That it produces a marked increase in the quantity of uric acid eliminated through the kidneys—in some cases amounting to as much as 100 or 200 per cent.—without a corresponding increase in the quantity of urea, seems to be established beyond question. Starkenstein (*A. E. P. P.,* 1911, lxv, p. 177) believes, however, that the increase in the uric acid is due to a diminished ability to oxidize the purin foods, but Folin and Lyman (*J. P. Ex. T.,* 1913, iv, p. 539) have shown that the increased elimination is accompanied by the diminution in the quantity of uric acid in the blood. It is generally accepted, therefore, that the increased elimination of uric acid is due to a greater capacity of the kidneys to excrete this substance, in other words, to a type of stimulation of kidney function. Myers and Killian (*J. P. Ex. T.,* 1921, xvi, 213) have shown that this stimulation of the kidney leads to a reduction not only of the amount of uric acid in the blood but also of the urea and that in cases of diseased kidneys its too free use may have an injurious effect upon the renal structure.

Phenylcinchoninic acid is a valuable remedy in the treatment of both acute and chronic *gout* and in those allied disorders generally spoken of as the *lithemic diathesis.* The improvement in these conditions is due probably in chief part to the increased output of the purin substances through the kidney, but in part, perhaps, also to its anodyne properties. Weintraud recommends that when using cinchophen in gouty disorders alkalies should be administered simultaneously in order to prevent the precipitation of uric acid in the kidney or bladder. Hanzlik and Scott (*J. A. M. A.,* 1921, lxxvi, 1728) have shown that large doses of cinchophen produce the same type of relief in *rheumatic* fever as is seen from the salicylates, that these quantities of cinchophen caused the characteristic ringing in the ears, nausea, etc., which are seen after full doses of the salicylates and also albuminuria and other evidences of renal irritation. From their observations they conclude that cinchophen is about equally efficient with the salicylates in acute rheumatism and that it is slightly less injurious to the kidney. Barron (*J. A. M. A.,* 1924, lxxxii, 2010) has reported severe circulatory collapse, which he believes an allergy, from a single dose of 15 grains. Mendel (*D. M. W.,* 1922, xlviii, 829) believes that cinchophen exerts an antiphlogistic action in all sorts of inflammatory conditions. This he attributes to an effect on the leucocytes.

In ordinary gouty or rheumatic conditions, phenylcinchoninic acid may be given in doses of from five to fifteen grains (0.3–1 Gm.) three times a day. In rheumatic fever Hanzlik and

Scott administered 1 Gm. (15 grains) every hour until there was evidence of its action, in improvement of the patient's condition or the occurrence of toxic symptoms. They found that partial relief occurred usually after about 4 or 5 such doses and that continued administration produced still more therapeutic effect so that most of their patients received eventually from 10 to 12 Gm. (2½ to 3 drachms). When given in small doses it may be administered in the form of tablet or enclosed in a capsule but when used freely the powder should be stirred up in the water as otherwise it is liable to cause considerable irritation of the stomach.

Dose, from eight to fifteen grains (0.5–1.0 Gm.) three times a day.

CINNAMOMUM. U. S. (Br.)

CINNAMON Cinnam. [Cinnamomum Saigonicum, U. S. P. IX]

" Cinnamon is the dried bark of *Cinnamomum Loureirii* Nees (Fam. *Lauraceæ*). Cinnamon yields not less than 2 per cent. of volatile ether-soluble extractive." *U. S.*

" Cinnamon Bark is the dried inner bark of shoots from the truncated stocks of Cinnamomum zeylanicum, *Breyn.* Obtained from cultivated trees. Imported from Ceylon, and distinguished in commerce as Ceylon cinnamon." *Br.*

Cinnamomi Cortex, *Br.;* Cinnamon Bark; Cortex Cinnamomi; Cannelle, *Fr.;* Zimmt, *G.;* Cannella, *It.;* Canela, *Sp.;* Kurundu, *Cingalese;* Karua Puttay, *Tamil.*

Both *cinnamonum* and *cassia* were terms employed by the ancients, but whether exactly as now understood it is impossible to determine.

From what source the ancients derived their cinnamon and cassia is not certainly known. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is probable that the Arabian navigators at a very early period conveyed this spice within the limits of the Phœnician and Grecian and subsequently of the Roman commerce.

The three principal varieties of cinnamon are known as Saigon Cinnamon, Ceylon Cinnamon and Cassia Cinnamon. Of these the U. S. P. has favored various ones in its previous editions. At present the U. S. P. recognizes only the Saigon variety and the Br. Ph. only the Ceylon. The genus Cinnamomum is a group of evergreen trees with mostly three-nerved leaves. The flowers which are either perfect or polygamous are of a pale yellow color and borne in panicles.

Cinnamomum Loureirii (Nees), the botanical source of Saigon Cinnamon, is of medium height, native to China and Japan. Its branches are glabrous and bear opposite and alternate, rigid, entire, elliptic to oblong, attenuate-acuminate leaves having a coriaceous texture. The petioles of these are one-half inch or less in length, the blades three to five inches long. The flowers are very small; they were, in the dried state, formerly an article of commerce under the name of *Flores Cassiæ.* The fruit is a berry which adheres to the receptacle.

The *Saigon cinnamon* is collected chiefly from wild trees especially in the mountainous districts of Annam, in French Indo-China. The greater portion of it is from branches and small stems and of good quality, although sometimes chips of the thick trunk bark are mixed with the quills. This variety is called Saigon because it is exported from the city of that name in the southern part of Cochin-China.

Cinnamomum zeylanicum (Nees) is a native of Ceylon and the neighboring Malabar coast. In the wild state it is a tree about 20 or 30 feet high, covered with a thick, scabrous bark. The branches are numerous, strong, horizontal, and declining, and the young shoots are beautifully speckled with dark green and light orange colors. The leaves are 4 to 7 inches long, petiolate, opposite for the most part, coriaceous, entire, ovate or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. In one variety the leaves are very broad and somewhat cordate. When mature, they are of a shining green upon their upper surface, and lighter-colored beneath. The tree emits no odor perceptible at any distance. The bark of the root has the odor of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odor when rubbed, and a hot taste. A volatile oil has been distilled from them. The petiole has the flavor of cinnamon. The flowers have a disagreeable, fetid odor. The fruit has a terebinthinate odor when opened, and a taste in some degree like that of juniper berries. A fatty substance, called *cinnamon-suet,* is obtained from it when ripe, by bruising it and then boiling it in water, and removing the oleaginous matter which rises to the surface and concretes upon cooling.

The *Ceylon cinnamon* is produced chiefly from cultivated plants, the principal gardens being in the vicinity of Colombo. Here the plant is never allowed to become a tree but by vigorous cutting back is forced to produce a bushy growth of slender stems. The seeds are planted four or five in a hill and the first five or six years the stems are pruned to be straight, then cut down and by coppicing produce a new crop of shoots. The cinnamon harvest commences in May and continues until late in October.

Before decortication the shoots are trimmed up, and the small pieces, when dried, constitute *cinnamon chips.* The bark is divided by longitudinal incisions, of which two are made in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation, which facilitates the separation of the epidermis. This, with the green matter beneath it, is removed by placing the strip of bark upon a convex piece of wood and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, and connects them also endwise, thus forming a congeries of quills which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds and bound together by pieces of split bamboo.

The *C. zeylanicum* is also cultivated to a limited extent in some of the West India islands—especially Martinique and Cayenne—and in Brazil. The bark from this source is generally regarded as inferior to that from Ceylon; it is known commercially as *Cayenne cinnamon.* The commercial supplies are imported from Colombo (Ceylon) and Calcutta (India).

Cinnamomum cassia (Nees) Blume is cultivated for the bark, buds and oil of cassia in the southeastern provinces of China. The bark after collection is scraped and dried. It is then made into bundles weighing from ½ to 1 kilo. which are tied with split bamboo, packed into bamboo cases which are then covered with bamboo mats. Very frequently these bundles contain chips and dirt in the center which are obscured from view by long quills on the outside. The commercial supplies of Cassia Cinnamon bark come from China and Calcutta, India. The poorer grades are known as "*Cassia lignea.*" From this tree is derived the spice known as *Cassia buds.* This consists of the calyx surrounding the young ovary. Cassia buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed ovary is sometimes removed, and they are then cup-shaped at top. They have a brown color, and the flavor of cinnamon.

C. iners Reinw. is distinguished from *C. zeylanicum* by the nervation of its leaves, which are also paler and thinner. It is probably only a variety, not a distinct species. It yields the so-called *wild cinnamon* of Japan. *C. obtusifolium* Nees, growing in Ceylon, Java, and on the mainland of India, is said to have been the chief source of the drug known formerly by the name of *Folia Malabathri* and consisting of the leaves of different species of Cinnamomum mixed together. *C. Culilawan* Blume of the Moluccas yields the aromatic bark called culilawan, noticed in Part II of this work; and similar barks are obtained from *C. Sintoc* of Java. *Massoy bark,* from which an aromatic volatile oil is obtained called *oil of massoy,* is the product of *Sassafras Goesianum* Leijom. In the mountains of Eastern Bengal, at a height of 1000 to 4000 feet, flourish *C. obtusifolium* Nees, *C. pauciflorum* Nees, and *C. Tamala* Nees et Ebern., and these, with other unknown species, afford quantities of bark which are shipped from Calcutta, Java, Timor, etc., to Europe under the name of *wild cassia.* The bark of the *C. pedatinervium* Meissn., a tree indigenous to Fiji, yields nearly one per cent. of a white aromatic volatile oil, with a pungent spicy taste. For constitution, etc., see *Proc. Chem. Soc.,* xix. These barks are mostly highly aromatic, resembling cinnamon more or less closely in flavor, and are distinguished by yielding to cold water an abundant mucilage. Holmes described the bark of *C. pedativum* Meis., and concludes that it might be of value as a source of safrol and linalool in *P. J.,* 1904, p. 892.

Description and Physical Properties.—"*Unground Cinnamon.*—In quills up to 30 cm. long and 4 cm. in diameter, the bark from 0.5 to 3.0 mm. in thickness, or in broken irregular pieces or in flattened slabs up to 8 mm. in thickness; the outer surface light brown to dark purplish-brown, with grayish patches of crustose lichens and numerous bud-scars, finely wrinkled when from young twigs, otherwise, more or less rough from corky patches surrounding the lenticels; inner surface reddish-brown to dark brown, granular and slightly striate; fracture short; odor characteristic and aromatic; taste sweetish, aromatic and pungent.

"*Structure.*—A narrow outer layer of more or less lignified cork cells followed by a layer of starch-bearing parenchyma with scattered stone cells and a nearly continuous zone of stone cells among which are small groups of bast-fibers with thickened and slightly lignified walls; inner bark with medullary rays 1 to 3 cells wide, inconspicuous sieve tissue, bast-fibers in groups of 2 to 20, mucilage and oil cells numerous and about the size of the parenchyma cells; parenchyma cells usually filled with starch or containing very small raphides of calcium oxalate; the lumina of parenchyma cells, stone cells and bast-fibers frequently filled with an amorphous reddish-brown substance, which is for the most part insoluble in the ordinary reagents. In the bark of the young twigs there is an epidermal layer with a thick, yellowish cuticle, fewer stone cells in the zone associated with bast-fibers, the inner bark narrower and with fewer secretion cells than in the older bark.

"*Powdered Cinnamon.*—Yellowish- or reddish-brown; starch grains numerous; single and 2- to 4-compound, the single grains from 0.005 to 0.025 mm. in diameter; stone cells irregular in shape, occasionally with one wall much thinner than the other walls, sometimes containing starch; bast-fibers from 0.3 to 1.5 mm. in length, with very thick and slightly lignified walls; parenchyma cells with reddish-brown walls; oil cells and mucilage cells not readily distinguishable.

"**Assay.**—Proceed as directed under volatile ether-soluble extractive.

"Preserve in tightly-closed containers." *U. S.*

According to Siebold, the bark of the large branches is of inferior quality and is rejected;

that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and odor, and is little esteemed, while the intermediate branches yield an excellent bark, about 2 mm. in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields a sweeter and less pungent oil.

Ceylon cinnamon occurs "in closely rolled quills, each about nine millimetres in diameter, and containing numerous smaller quills or channelled pieces. Dull, pale yellowish-brown, darker on the inner surface; thin, brittle and splintery; entirely free from cork; marked with small scars or holes and with faint, shining, wavy longitudinal lines. The powdered Bark exhibits abundant parenchymatous tissue with brown cell-walls, isolated bast-fibers not more than 30 microns in diameter, small simple or compound starch grains and thick-walled sclerenchymatous cells, but no cork or fragments of wood. Fragrant odor; taste warm, sweet and aromatic. Ash not more than 5 per cent." *Br.*

"Under the microscope, sections of Ceylon Cinnamon usually show no cork but an almost continuous outer layer of stone cells, among which are small groups of bast-fibers resembling those found in *Saigon Cinnamon;* in the inner bark occur numerous bast-fibers singly or in small groups, medullary rays 1 to 2 cells in width, usually with raphides of calcium oxalate; parenchyma with either reddish-brown contents or more or less filled with starch grains; scattered throughout the parenchyma occur oil secretion cells and mucilage cells. The powder is light brown or yellowish-brown; starch grains numerous, varying from spherical to polygonal, from 0.003 to 0.02 mm. in diameter, frequently in small aggregates; bast-fibers from 0.3 to 0.8 mm. in length, usually single, spindle-shaped, with attenuated ends, the walls being very thick and but slightly lignified; colorless stone cells resembling those of *Saigon Cinnamon;* numerous cellular fragments with yellowish-brown walls or contents; cork cells few or none; calcium oxalate in raphides, from 0.005 to 0.008 mm. in length. Ceylon Cinnamon yields not less than 0.5 per cent. of volatile extractive soluble in ether." *U. S. IX.*

When distilled Ceylon Cinnamon affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavor. It is brought to this country from England, but it is costly. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavor, and are little if at all superior to the best Chinese. The finer variety of *Cayenne cinnamon* approaches in character that above described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young is scarcely distinguishable from the cinnamon of Ceylon.

Chinese cinnamon, or *Cassia* (*Cinnamomum Cassia,* U. S., 1890), occurs in quills, usually single, sometimes double, very rarely more than double, from 30 to 60 cm. long, 2 to 5 cm. wide, and 0.2 to 3 mm. thick. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker color than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent but less sweet and grateful taste, and though of a similar odor, is less agreeably fragrant. It is the kind almost universally kept in our shops. Under the name of cassia have also been brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, or perhaps derived from inferior species. It is said that cinnamon from which the oil has been distilled is sometimes fraudulently mixed with the genuine. These inferior kinds are detected, independently of their greater thickness and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice. Chinese cinnamon is "in quills of varying length and about 1 mm. or more in thickness; nearly deprived of the corky layer, yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic." *U. S.* 1890. Cassia is no longer official in the U. S. P., it having been dropped at the 8th Revision.

Powdered cinnamon is often grossly adulterated with sugar, ground walnut shells, galanga rhizome and various other substances. Galanga, according to Schmitz-Dumont, may be detected by the presence of small club-shaped, rod-shaped, partly bent, microscopic pieces of resinotannol. (*Zeit. oeff. Chem.*, 1903, No. 2.) Powdered cassia buds are frequently added to the inferior cinnamon powders, but can hardly be looked upon as an adulterant, as they contain a larger proportion of volatile oil than the lower grades of cinnamon.

The *Pharmacographia* gives the following tests for distinguishing powdered cassia from powdered cinnamon, and for recognizing the inferior varieties of cassia. Make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected powder; when cool and strained, test a fluidounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately produced. The cheap kinds of cassia known as *cassia vera* may be distinguished from the more valuable Chinese cassia as well as from cinnamon by their richness in mucilage; this can be extracted by cold water; it is a thick glairy liquid, giving dense ropy precipitates with corrosive sublimate or neutral lead acetate, but not with alcohol.

The coarser cassia bark, or *cassia lignea,* usually has some of the external or corky layer adherent to it, and always the parenchymatous mesophlœum or middle bark, but the inner bark constitutes the chief mass. Isolated bast fibers and thick-walled stone cells are scattered even through the outer layers of a transverse section. In the middle zone they are numerous, but do not form a coherent sclerenchymatous ring as in Ceylon cinnamon. The innermost part of the bast shares the structural character of cinnamon, with differences due to age, as, for instance, the greater development of the medullary rays. Oil cells and mucilage cells are likewise distributed among the parenchyma of the former. The finest cassia or Chinese cinnamon has the three layers described in Ceylon cinnamon, but is distinguished by the adherent outer parenchymatous and suberous layer. For an excellent description of the microscopical structure of the commercial cinnamon see Winton and Moeller, "*The Microscopy of Vegetable Foods.*" Spaeth gives the microscopical characteristics of the several kinds of cinnamon, discusses the adulterants of powdered cinnamon and the means of detection in *Ph. Centralh.*, 1908, pp. 724, 729. Rosenthaler and Reis give an excellent pharmacognostical study of Seychelles Cinnamon in *B. P. G.*, 1909, p. 490.

The chief substitute and adulterant for both Saigon and Cassia barks within recent years has been the *Fagot* or *Batavia cassia.* This bark is obtained from *Cinnamomum Burmanni* Blume, a tree native to Java and probably other East India islands. It occurs mostly in double quills that are scraped, up to 3 mm. thick, light-brown to reddish externally, extremely mucilaginous and less aromatic than the other 3 main varieties. The powdered bark, unlike the other cinnamon barks described, forms a shiny mass in water and may also be distinguished from these by the presence therein of tabular and prismatic crystals of calcium oxalate.

R. Windisch reports that in the case of nine samples of cinnamon bark, which he examined four yielded an ash, dark-brown in color, which was shown to contain considerable iron. The ash in these samples varied from 6 to 10 per cent. as compared with 2.11 per cent. in normal samples. The addition was found to consist of iron ochre, from 6 to 10 per cent. of this material having been added. (*Ztsch. Unters. Nahr.-u. Gennssm.*, 41, 1921, p. 78.)

Constituents.—Cinnamon bark contains from 0.5 to 1.0 per cent. of a peculiar essential oil (see *Oleum Cinnamomi*), some gum, a coloring matter and a tannin of the variety which gives blue-black precipitate with ferric salts. Thornton (*A. J. P.*, 1895, 400) has examined the tannin of *C. Cassia.* He found it to amount to about 3.90 per cent., as an average of three different determinations on different samples. He found it impossible to extract the tannin by any one of several methods tried, and concludes that it either has the phlobophene (anhydride) character as it exists in the drug or acquires such character when brought into contact with water. Bucholz found in 100 parts of *cassia lignea* 0.8 of volatile oil, 4.0 of resin, 14.6 of gummy extractive (probably including tannin), 64.3 of lignin and bassorin, and 16.3 of water, including loss.

Assay.—As the therapeutic value of cinnamon depends upon the volatile oil, of which the most important ingredient is cinnamic aldehyde, Fellenberg (*D. C.*, 1916, lx, 755) has suggested the *assay* of cinnamon for this aldehyde by the following process: 1 Gm. of the powdered bark is heated with 40 cc. of alcohol for ten minutes in a flask provided with a reflux condenser. The alcohol is then distilled until about 30 cc. is obtained, when 100 cc. of water is added to the flask and distillation continued until the distillate measures 100 cc.; 5 cc. of this distillate are mixed with 2 cc. of a 5 per cent. alcoholic solution of isobutyl alcohol and 3 cc. of 38 per cent. alcohol. To this is added 20 cc. of concentrated sulphuric acid and allowed to stand for forty-five minutes. The color produced is compared with that of a 2 per cent. solution of cinnamic aldehyde in 38 per cent. alcohol produced by the same method. He found the proportion of cinnamic aldehyde in Ceylon cinnamon to be from 1.3 to 1.8 per cent. and in Chinese cinnamon from 1.25 to 2.77 per cent. (For another method of assaying cinnamon see Lanten Schläger, *A. Pharm.*, 1918, cclvi, 87.)

Uses.—Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, distinctly astringent, and, like most other substances of this class, more powerful as a local than as a general stimulant. It is seldom prescribed alone, though, when given in powder or infusion, it will sometimes allay *nausea,* check *vomiting,* and relieve *flatulence.* It is chiefly used as an adjuvant, and enters into a great number of official preparations. It is often employed in *diarrhea,* in connection with chalk and astringents.

Dose, of powder, ten to twenty grains (0.65 to 1.3 Gm.).

COCAINA. U. S., Br.

COCAINE Cocain.

"An alkaloid [$C_{17}H_{21}O_4N$] obtained from the leaves of *Erythroxylon Coca* Lamarck and other species of *Erythroxylon* (Fam. *Erythroxylaceæ*)." *U. S.* "Cocaine, $C_{17}H_{21}NO_4$, is an alkaloid obtained from the leaves of Erythroxylum Coca, *Lam.*, and its varieties." *Br.*

Benzoyl-ecgonine-methyl-ester; Benzol-methyl-ecgonine; Cocainum; Cocaine, *Fr. Cod.;* Cocain, Kokain, *G.*

For description of Coca, from which this alkaloid is obtained, see Part II.

Squibb's process for cocaine and its hydrochloride is as follows: Coarsely ground coca leaves are repercolated with an aqueous five per cent. solution of sulphuric acid, and a very dense, slightly acid percolate is obtained; this is thoroughly agitated with pure coal oil and an excess of sodium carbonate; the liberated alkaloid is retained by the coal oil, and is nearly free from coloring matter; the oily solution is then agitated with acidulated water, and again precipitated by sodium carbonate in the presence of ether. The ethereal solution of cocaine is treated with diluted hydrochloric acid fractionally, and the nearly colorless solutions of cocaine hydrochloride are cautiously evaporated in shallow porcelain pans almost to dryness. The product is in the form of a white, crystalline, granular powder, and is a nearly pure anhydrous salt. (*Ephem.*, 1887, 906.) For Henrique's process see *Proc. A. Ph. A.*, 1895, 999.

Owing to the small yield, it is found more profitable to manufacture cocaine in South America and export it, thus saving the expense of transporting the bulky coca leaves.

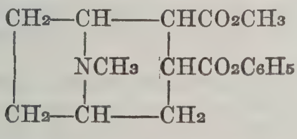
The cocas contain a number of alkaloids which Henry (*Plant Alkaloids*, 1924, p. 95) divides into four groups; (1) the cocaines, (2) pseudotropeines, (3) acylecgonines, (4) hygrines. In the first group is cocaine (methyl benzoyl ecgonine), *cinnamyl-cocaine* (methyl-cinnamoylecgonine), and alpha- and beta-*truxilline*, $C_{38}H_{46}O_8N_2$. Alphatruxilline is also known as *cocamine* and *isatropyl-cocaine.*

The second group comprises one alkaloid, tropacocaine, which is a benzoyl-pseudotropein. This alkaloid is important not merely because of its use in medicine but also because the base *pseudotropine* is isomeric with the base tropine found in atropine. Tropacocaine is described in Part II.

In the fourth group are *hygrine,* $C_8H_{15}ON$, *cuscohygrine,* $C_{13}H_{24}ON_2$ and *betahygrine,* $C_{14}H_{24}ON_2$. These are comparatively simple compounds and are liquid at ordinary temperatures.

With the exception of ecgonine and anhydroecgonine, all of the bodies in the foregoing list are easily decomposable, splitting up when heated to from 80° to 100° C. with hydrochloric acid, or when boiled with alcoholic potassium hydroxide.

Cocaine has the following structural formula:



The characteristic group conferring the anesthetic properties is the benzoyl group.

It may be identified by treatment with strong acids and heating, the decomposition into methyl alcohol and benzoic acid being followed by the production of methyl benzoate with its very characteristic odor. It is easily decomposed by heat in the presence of moisture on solutions of its salts may not be sterilized by heat.

Much of the cocaine used in this country is prepared from the crude alkaloid which is manufactured in the countries where the plant grows. The alkaloids are extracted from the leaves by kerosene or some other cheap immiscible solvent in the presence of an alkali, the alkaloids being separated from the solvent with dilute sulphuric acid from which cocaine is precipitated by sodium carbonate. This crude substance represents about 90 per cent. of cocaine. A good deal of cocaine is manufactured in Germany from the Java coca leaves which contain chiefly cinnamyl cocaine. This alkaloid is hydrolized by boiling with diluted hydrochloric acid and the ecgonine so obtained treated with benzoic anhydride and methyl iodide. The other coca bases may also be converted into cocaine by a similar process as suggested by Liebermann (*B. Chem. G.*, 1888, xxi, 3196).

Description and Physical Properties.—"Colorless crystals, or a white, crystalline powder. It is odorless, and is stable in the air. One Gm. of Cocaine is soluble in about 600 cc. of water, 6.5 cc. of alcohol, 0.7 cc. of chloroform, 3.5 cc. of ether, 12 cc. of olive oil, and in 30 to 50 cc. of liquid petrolatum, at 25° C. One Gm. is soluble in 270 cc. of water at 80° C. It is very soluble in warm alcohol.

"Cocaine melts between 96° an 98° C. Its saturated aqueous solution is alkaline to litmus paper. Its solution in diluted acids is lævorotatory. Heat about 0.1 Gm. of powdered Cocaine with 1 cc. of sulphuric acid for five minutes at 100° C., then cautiously mix with 2 cc. of distilled water: the aromatic odor of methyl benzoate is noticeable and on cooling crystals of benzoic acid separate.

"The ash from 0.5 Gm. is negligible. Dissolve 0.1 Gm. of finely powdered Cocaine in 1 cc. of sulphuric acid: not more than a slightly yellow tint is produced (*readily carbonizable substances*). Dissolve 0.3 Gm. of finely powdered Cocaine in 1 cc. of normal hydrochloric acid, gently warming, if necessary, to aid solution, and dilute with distilled water to 15 cc.: 5 cc. portions of this solution do not respond to the tests for *cinnamyl-cocaine* and for *isoatropyl-cocaine* under *Cocainæ Hydrochloridum.*" *U. S.*

The British Pharmacopœia gives the following description: "In colorless monoclinic prisms. No odor; taste bitter, followed by a sensation of tingling and numbness. Soluble in 10 parts of *alcohol* (90 per cent.), in 4 parts of *ether,* in 0.5 part of *chloroform,* and in 24 parts of *olive oil;* almost insoluble in *water.* Melting point 98° C. The dry salt obtained by dissolving Cocaine in *water* acidified, with *hydrochloric acid,* and evaporating the solution, responds to the tests described under 'Cocainæ Hydrochloridum.'" *Br.*

Uses.—For most purposes cocaine hydrochloride is preferred to the base, but the latter is used in ointments and oily solution because of its greater solubility in fatty substances. Other salts of cocaine have been used in medicine. *Cocaine borate* has been recommended for ophthalmological uses. *Cocaine hydriodide* which occurs in colorless crystals moderately soluble in water, has been recommended by R. Marcus as being especially suitable for use by cataphoresis for the production of anesthesia. For medicinal uses, see *Cocaine Hydrochloride.*

Dose, one-eighth to one-fourth grain (0.008–0.016 Gm.).

Off. Prep.—Oleatum Cocainæ, *N. F.;* Unguentum Cocainæ, *Br.*

COCAINÆ HYDROCHLORIDUM. U. S., Br.

COCAINE HYDROCHLORIDE Cocain. Hydrochl. [Cocainum Hydrochloricum P. I.]

"[$C_{17}H_{21}O_4N.HCl$]." *U. S.* "Cocaine Hydrochloride, $C_{17}H_{21}NO_4,HCl$, is the hydrochloride of the alkaloid cocaine." *Br.*

Cocainæ Hydrochloras, *U. S.* 1890; Cocaine Chloride; Hydrochlorate of Cocaine; Cocainæ Chlorhydricum; Chlorhydrate de Cocaine, *Fr. Cod.;* Cocainum hydrochloricum, *P. G.;* Cocainhydrochlorid, *G.;* Cloridrato di Cocaina, *It.;* Cloruro de Cocaina, *Sp.*

For account of sources and chemical structure see under *Cocainæ.*

Description and Physical Properties.—"Colorless, transparent crystals, lustrous leaflets, or a white, crystalline powder. It is odorless and is stable in the air. One Gm. of Cocaine Hydrochloride is soluble in 0.4 cc. of water, 3.2 cc. of alcohol, and in 12.5 cc. of chloroform, at 25° C. One Gm. is soluble in 2 cc. of alcohol at 60° C. It is soluble in glycerin and insoluble in ether.

"Melting point not below 183° C. Add five drops of a solution of chromium trioxide (1 in 20) to 5 cc. of a solution of Cocaine Hydrochloride (1 in 50): a yellow precipitate is produced which redissolves on shaking the mixture. On the addition of 1 cc. of hydrochloric acid, a permanent, orange-colored, crystalline precipitate is formed. A solution of about 0.01 Gm. of Cocaine Hydrochloride in 1 cc. of distilled water yields on the addition of 2 cc. of tenth-normal potassium permanganate a violet, crystalline precipitate which appears brownish-violet when collected on a filter, and shows characteristic, crystalline aggregates under the low power of a microscope. Heat about 0.1 Gm. of powdered Cocaine Hydrochloride with 1 cc. of sulphuric acid for five minutes, then cautiously mix with 2 cc. of distilled water: the aromatic odor of methyl benzoate is noticeable and on cooling crystals of benzoic acid separate. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid.

"The ash from 0.5 Gm. is negligible. Dissolve 0.5 Gm. of Cocaine Hydrochloride in 1 cc. of sulphuric acid: not more than a slightly yellow tint is produced (*readily carbonizable substances*). A solution of 0.5 Gm. of Cocaine Hydrochloride in 10 cc. of distilled water requires for neutralization not more than 0.5 cc. of fiftieth-normal sodium hydroxide, using one drop of methyl red T.S. as indicator. Mix 5 cc. of an aqueous solution of the salt (1 in 50) with 0.3 cc. of normal sulphuric acid and 0.1 cc. of tenth-normal potassium permanganate: the violet color does not disappear entirely within a half hour (*cinnamyl-cocaine*). Dilute 5 cc. of an aqueous solution of the salt (1 in 50) in a beaker with 80 cc. of distilled water, add 0.2 cc. of ammonia T.S., and stir the solution vigorously during five minutes, occasionally rubbing the sides of the beaker with a stirring rod: a crystalline precipitate of cocaine is formed and the supernatant liquid is clear (*isoatropyl-cocaine*). The presence of 0.5 per cent. of isoatropyl-cocaine will prevent the formation of nearly all of the precipitate, and will cause the supernatant liquid to be milky." *U. S.*

"In colorless prismatic crystals, or a crystalline powder. No odor; taste bitter, followed by a sensation of tingling and numbness. Soluble in 0.5 part of *water,* and in 3 parts of *alcohol* (90 per cent.); insoluble in *olive oil.* Melting point 182° to 186° C. Yields the *reactions* characteristic of chlorides. An aqueous solution is neutral to *litmus,* and when applied to the eye dilates the pupil. When moistened with *nitric acid,* the mixture evaporated to dryness, and 1 millilitre of *alcoholic solution of potassium hydroxide* added, a characteristic odor is evolved, recalling peppermint. The addition of 3 drops of *N/10 solution of potassium permanganate* to a solution of 0.1 gramme of the salt in 5 millilitres of *water* to which 3 drops of *diluted sulphuric acid* have been added, gives a violet color, which, if dust is excluded, does not fade in half an hour (absence of cinnamyl-cocaine and certain other coca alkaloids). If 0.1 gramme is dissolved in 100 millilitres of water in a glass beaker, 0.25 millilitre of *solution of ammonia* stirred in, and the mixture set aside for fifteen minutes, the sides of the beaker being occasionally and not too vigorously rubbed with a glass rod, a crystalline deposit separates, leaving the supernatant liquid clear (limit of amorphous alkaloid). 0.05 gramme dissolves in 1 millilitre of cold *sulphuric acid* or cold *nitric acid* without coloration, but with hot *sulphuric acid* the salt chars, evolving an agreeable odor and yielding a sublimate of benzoic acid. Loses not more than 1 per cent. of its weight when dried at 100° C. No appreciable ash." *Br.*

D. Scherbatschew recommends for differentiating cocaine and several of its commoner substitutes placing three drops of the aqueous solution of the suspected substance on a glass slide and adding one drop, respectively, of each of the following reagents: (1) Ten per cent. solution of NH_3. (2) Ten per cent. solution of KOH. (3) A saturated solution of $NaHCO_3$. Stovaine and holocaine give precipitates with all three reagents; betaeucaine gives only a slight precipitate with KOH and none with the other two; nirvanine gives a precipitate with NH_3 and a slight one with KOH but none with $NaHCO_3$; alypine precipitates decidedly with NH_3 and KOH, but not with $NaHCO_3$; novocaine precipitates with KOH but not with the other two. Cocaine and tropacocaine are identified by Hankin's $KMnO_4$ test.

Alphaeucaine hydrochloride gives a yellow precipitate when 5 cc. of a 1 per cent. solution are treated with three drops of a 5 per cent. solution of chromic acid. Cocaine hydrochloride does not. Betaeucaine hydrochloride when rubbed with dry mercurous chloride and then moistened with alcohol yields no color, cocaine hydrochloride when similarly treated turns grayish black. Holocaine hydrochloride gives in aqueous solution a violet precipitate with calcium hypochlorite, cocaine hydrochloride does not. Cocaine and procaine are distinguished by the potassium permanganate test (see *Procainæ Hydrochloridum*).

Batta and Jenot describe in detail (*Chem. News.*, 1921, cxxiii, 65) a number of tests for distinguishing between cocaine, stovaine and procaine.

Uses.—It is necessary to distinguish clearly between the local and systemic effects of cocaine. When locally applied cocaine is a paralyzant to the peripheral ends of the sensory nerves, and to a lesser degree to the motor nerves, and stimulating to the muscular coats of the blood vessels. As a result of these actions when painted over mucous membranes it causes a blanching of the part and diminished sensation. It produces not only lessened sensibility to pain and touch but also of the acuity of the special senses, thus it diminishes in the mouth the power of taste and in the nose that of smell.

Systemically it is a stimulant to all parts of the central nervous system including the brain, the spinal cord, and the medulla. Its effects upon the brain are shown by an exaltation of the intellectual faculties similar to that which is produced by caffeine. In overdose it produces a delirium somewhat suggesting that of atropine, to which it is chemically related. Its action upon the spinal cord is shown by increased activity of the reflexes but the convulsions which are seen in cocaine poisoning both in the lower animals and in man seem to be due to an action upon the motor area of the brain, rather than to its effect on the cord. The effects on the medullary centers are shown by an increase of the rapidity of the respiration and sometimes also of its depth. After toxic doses the primary stimulation is followed by a depression of the respiratory center. The blood pressure is elevated chiefly through an action upon the vasomotor center, although there is some evidence that it also stimulates the heart. Concerning the changes in the pulse rate there is difference of opinion. According to Reichert (*P. M. J.*, 1902) small doses slow the pulse rate by stimulating the cardio-inhibitory center, moderate quantities increase the rate by depressing the inhibitory mechanism, while after large toxic doses there may be a second slowing of the heart through depression of its motor ganglia. Cocaine in moderate quantities also stimulates both the voluntary and involuntary muscle fibers. It appears also to have some effect upon the nutritive processes since it causes a marked rise in the bodily temperature. Whether this increase in temperature is due to a direct action upon the thermogenic centers or is simply the result of muscular activity, is as yet not definitely settled. When instilled into the eye it causes dilatation of the pupil, usually without paralysis of accommodation. The widening of the pupil seems to be the result of an action upon the peripheral ends of the sympathetic nerve and can be further increased by the instillation of atropine.

Cocaine is used in medicine both as a local and a systemic remedy. Internally it is of value as a circulatory and respiratory stimulant and is occasionally of use as a cerebral stimulant or as a tonic. Its employment, however, in any condition which requires prolonged administration of the drug is fraught with so great danger of formation of a habit that it is rarely justifiable. In *narcotic poisonings* the simultaneous stimulation of the respiration, circulation, and cerebrum makes it a remedy of particular value.

The most important use of cocaine is as a local application to mucous membranes either for the purpose of contracting the blood vessels or of lessening sensation. For the former action it is useful to relieve congestions such as *hay fever, coryza,* or *laryngitis,* and to control or prevent *hemorrhage* from the nose and throat. There are two great drawbacks to cocaine in this use, the first that the primary contraction of the blood vessels is liable to be followed by a reactive relaxation, and the second is the ever present peril of habit-formation. As a local anesthetic it is useful in operations on the eye, nose, throat, etc., in painful *hemorrhoids, fissure in ano, vomiting, gastralgia,* and other painful diseases of the mucous membranes. While cocaine passes through all mucous membranes with greater or less ease, the unbroken skin offers a practically impassable barrier. Nevertheless, the drug is often used as a local anesthetic, especially for operative purposes, in all parts of the body. To obtain its action it is necessary that the drug be introduced beneath the skin in some manner; it may be either simply injected hypodermically or introduced into the vicinity of the large nerve trunks, or even injected into the spinal canal. The methods of using cocaine as a local anesthetic are too numerous and complex for consideration in this work and the reader is referred to treatises on Surgery. There is a widespread belief among both pharmacists and physicians that solutions of cocaine cannot be sterilized by heat without danger of decomposition, but a number of chemists have shown that if the solution is not allowed to become alkaline the degree of hydrolysis is insignificant.

Cocaine is also useful for the purpose of dilating the pupil, where paralysis of accommodation is not desired, as for example in ophthalmoscopy.

For local application to mucous membranes an aqueous solution of one of the salts of cocaine, ordinarily the hydrochloride, is usually preferred; Gross, however (*A. E. P. P.*, 1910, lxiii, p. 80) presents evidence that the basic cocaine is a much more powerful anesthetic than its salt and some authorities give preference to oily solutions of basic cocaine.

TOXICOLOGY.—As has been pointed out by Kamenzove (*A. I. P. T.*, 1911, xxi, p. 5) there are two distinct types of cocaine poisoning, one characterized by circulatory failure and the other by neurotoxic symptoms. The first type is usually seen after relatively small doses of the drug in persons who possess an idiosyncrasy against it. The prominent symptoms are pallor of the face, vertigo, nausea, failure of the pulse, and usually more or less complete loss of consciousness. The treatment of this type of poisoning is to place the patient in a horizontal position, give rapidly acting stimulants such as hypodermic injections of ammonia or camphor. Kamenzove believes that these symptoms are due to arterial spasm causing anemia of the brain.

The other group of cocaine poisonings is characterized by delirium, increased reflexes, more or less violent convulsions, the pulse usually being rapid and fairly strong but later may become weak, and syncope and cyanosis may intervene. The delirium is frequently associated with hallucinations and at times the patient may develop a violent mania of even homicidal character, as in a case reported by Mattison. In fatal cases death is usually due to respiratory failure although the circulation is also depressed.

In the treatment of cocaine poisoning, as the alkaloid rarely enters the system through the alimentary canal, emptying the stomach and the use of chemical antidotes is generally not indicated. Eggleston and Hatcher (*J. P. Ex. T.*, 1919, xiii, p. 433) from an experimental study highly recommend, in the treatment of cocaine poisoning, the intravenous injection of epinephrin combined with artificial respiration. Nielsen and Higgins (*J. Lab. Clin. M.*, 1923, viii, 440) finds that pituitary solution exercises both a preventive and curative effect. In the convulsive type of poisoning, Tatum (*J. A. M. A.*, 1925, lxxxiv, 1177) finds that the intravenous injection of barbital sodium is of much value provided it is administered promptly. The assertion that calcium chloride is antidotal to cocaine has been shown erroneous by Weiss (*J. A. M. A.*, 1923, lxxxi, 1282).

The habitual use of cocaine as a narcotic stimulant has reached an extent of sociological importance. In the United States the conditions under which it may be prescribed or dispensed are strictly limited both by Federal and, in many states, by state laws. (See *U. S. Pub. Health Rep.*, 1916, xxxi, and 1924, xxxix.) The cocaine habit is not only one of the most seductive but also one of the most rapidly injurious and difficult of eradication of all drug habits. The characteristic symptoms are changes in the mental and moral qualities, especially characterized by alternate periods of exaltation and depression, loss of appetite and of weight, peculiar pallor of the skin, insomnia, and general failure of health. A symptom which is seen in many cases and is said to be characteristic of chronic cocaine poisoning, is a sensory hallucination, as of some foreign body under the skin or of insects crawling over the person.

Dose, of the salts of cocaine, from one-fourth to one-half grain (0.016–0.03 Gm.).

Fish Berry, Indian Berry, Levant Berries; Coque du Levant, *Fr.*; Kokkelskörner, Fischkörner, Tollkörner, *G.*; Oriental Berries.

Anamirta Cocculus (L.) Wight et Arnott is a perennial woody climber with alternate pinnate-reticulate, cordate leaves, axillary panicles of small flowers and red kidney-shaped drupaceous fruits, each containing an urn-shaped seed. It is indigenous to mountainous districts of Southern Asia and the East Indies and particularly abundant along the Malabar coast.

The natives collect the fruits (drupes) from wild plants and dry them in the sun. Most of the drug is sent to Calcutta and Bombay whence it is shipped to London and the United States.

The fruit bears some resemblance to the bay laurel berry, but is not quite so large, and may be distinguished by the fact that in the *Cocculus Indicus* the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directed that "the kernels should fill at least two-thirds of the fruit."

Description and Physical Properties.—"*Unground Cocculus.*—Reniform, 8 to 13.5 mm. long, 7 to 11 mm. wide and 7 to 10 mm. thick, blackish brown or reddish brown, wrinkled; hilum and micropyle close together; separated by a shallow sinus and connected by an obscure ridge running around the convex side; distinct circular stalk-scar. Pericarp tough, about 1 mm. thick, outer layer brownish, inner layer light yellow enclosing a single seed. Seed whitish yellow, urn-shaped, its longitudinal and transverse sections crescent-shaped, taste bitter, the seed intensely bitter.

"*Powdered Cocculus.*—Brown; numerous fragments of epicarp which become reddish brown on the addition of alkalies; endosperm parenchyma containing many fixed oil globules, aleurone grains up to 0.050 mm. in length, and acicular crystals, the latter soluble in dilute hydrochloric acid and insoluble in water, alcohol, and potassium hydroxide T.S.; numerous thick-walled, mostly non-lignified fibers; tracheæ, spiral." *N. F.*

According to Merck its main constituents are *menispermine, paramenispermine, picrotoxin,* $C_{30}H_{34}O_{13}$, *picrotoxic acid* and *cocculin.*

Picrotoxin, a neutral principle, is found in the seed portion, while the alkaloids menispermine and paramenispermine are found in the fruit wall. According to Tunmann, picrotoxin sublimes mostly at 215° to 225° C. without forming crystals. Heating the sublimate with 5 per cent. ferric chloride solution under the cover glass until bubbles appear, yields, upon cooling, typical pentagonal crystals. For further description of these principles see *Picrotoxin,* Part II.

Uses.—*Cocculus Indicus* is used in India to stupefy fishes. Both its poisonous properties and any therapeutic virtues it may contain depend upon picrotoxin (see Part II). It has been used in medicine for the purpose of destroying vermin in the hair, but it is an extremely dangerous drug. For cases of poisoning see Sozinsky (*M. News,* 1883, xliii, p. 485), Swift (*N. Y. M. J.,* 1897, lxvi, p. 664), and Haines (*P. M. T.,* 1884, xiv, p. 748).

Off. Prep.—Tinctura Cocculi, *N. F.*

COCCUS. U. S., Br.

COCHINEAL

"Cochineal consists of the dried female of the insect *Coccus cacti* Linné (Fam. *Coccidæ*), enclosing the young larvæ." *U. S.* "Cochineal is the dried fecundated insect, Coccus cacti, *Linn.*" *Br.*

Coccionella; Cochenille, *Fr. Cod.;* Scharlachwurm, *G.;* Cochinilla, *Sp.*

The cochineal insect is indigenous to Mexico, Peru and Central America and in general appearance resembles a wood louse. It is usually found upon certain flat-stemmed forms of the Cactus family, chiefly species of *Nopalea.* The red dye found in the remains of the female insect has been long esteemed by the old races in these subtropical countries. Indeed, not only did they appreciate its value, but in order to increase the supplies, the cacti with the insects were successfully cultivated many years before even Cortez landed in Mexico in the early part of the sixteenth century.

The cochineal insect belongs to the order *Hemiptera,* suborder *Homoptera,* family *Coccidæ.* The latter includes the scale-like insects which are characterized by the fact that the wingless female dies shortly after producing her eggs, the latter being covered up by her dead scale-like body. In the case of the cochineal insect the larvæ are found, as will be shown later on, within her inflated body. In the group of the *Coccidæ* we find a number of interesting scale insects. Here we find the lac insect from which stick-lac of commerce is produced, the latter being a resinous substance excreted by the *Coccus* (*Carteria*) *lacca* which inhabit the branches of several tropical trees. From the bodies of these insects also certain coloring agents known as "lac dyes" are produced. China wax, the excretion of an insect known as "Pela" (*Ericerus pela*) is also the product of a scale insect belonging to this family. Comstock states that there are many species of the *Coccidæ* which excrete wax in considerable quantity.

The cochineal insect was first described by Hernandez in 1651. It is ordinarily in scientific works referred to as *Coccus Cacti* Linné. In the eighth edition of the U. S. Pharmacopœia the name was changed to *Pseudococcus Cacti* (Linné) Burmeister. In a "Catalogue of The Coccidæ of the World," Maria E. Fernaldo gives preference to the name *Dactylopius Coccus* Costa. In Pharmacopœial work we are justified, however, in using the Latin title that has been given precedent by usage, namely *Coccus Cacti,* as otherwise we might change the name with each revision as our knowledge of these insects is extended.

The cochineal insect feeds upon various species of the *Cactaceæ,* more especially the Nopal plant, *Nopalea* (*Opuntia*) *coccinellifera* (Mill.) S.-Dyck, a native of Mexico and Peru. It has spread into other parts of South and Central America and has been introduced into the West Indies, East Indies, Canary Islands, Southern Spain, Algeria, and is said to be found in Florida and California.

The cultivation of cochineal is rather simple in a tropical climate, all that is necessary is to have the cochineal insects and the proper cacti. During the rainy season the insects are protected by spreading shelters over the plants on which they are propagated. When the weather conditions have become favorable the insects are "sown" on the cacti in the open fields, where fecundation takes place. After this the females attach themselves to the plant and when their bodies have become swollen from the development of the enormous number of eggs, they are scraped off and killed either by boiling water or by the fumes of burning sulphur. Some of the insects are left behind and deposit their eggs, the female dying after the eggs are laid; these furnish a seed for a new crop.

Kraemer has written an extended monograph on the nature and structure of cochineal (*A. J. P.,* 1913, p. 444), and gives the following facts concerning the life history of the cochineal insect. The female insect is without wings, about 2 mm. in length and consists of from 9 to 12 segments. It is somewhat globular, becoming later distinctly ovoid. In general appearance, as it creeps over the cactus stems, it is convex on the upper, that is the dorsal surface, and somewhat flattened or concave below, that is, on the ventral surface. It is covered with glaucous dust formed of wax. This wax is a protective secretion and is formed as a glandular secretion by the "wax pores" and wax hairs, the anatomy of which has been worked out by Mayer. The antennæ are rather short, consisting of 8 parts. The threadlike beak or proboscis, forming a sucking apparatus, is a very fully developed. There are 3 pairs of legs which in the commercial article do not show more than 3 joints. Projecting from the posterior portion of the abdomen there are 2 short hairs or bristles, which are wanting in the commercial article.

The male is more elongated and ellipsoidal in outline and is provided with 2 transparent wings which reach beyond the extremity of the abdomen and cross each other longitudinally on the back. The head is distinguished from that of the female in being furnished with a rudimentary beak and with 2 long feathery antennæ. It is said that the male insect is reproduced in large numbers; the larvæ in the commercial cochineal does not show this to be the case. As a matter of fact, actually only one male is necessary for about 300 females. Upon performing their functions the male insects die and are blown away. They are therefore never seen in the commercial article.

The female insect after fecundation grows larger as the young larvæ develop, becoming eventually about twice her original size. She meanwhile attaches herself to the surface of the stems of the cacti, her body penetrating into the upper layer of cells. The upper dorsal surface becomes more or less cartilaginous in structure and more or less convex in shape. The lower surface is drawn toward the upper surface and in this membranous cradle the larvæ are developed. It requires about eight days for the larvæ to become full grown, when they are said to resemble the parents with the exception that they are covered with a short hairy coating. In another week they attain maturity and the females of the new generation are ready to form broods in their turn. The life history of the cochineal insect is completed in about six weeks, two weeks being required for the development of the mature insect from the egg; during the next two weeks the female crawls over the fleshy stems of the cacti, the male in the meanwhile being able to fly about; then the female attaches herself to the tissues of the Nopal plants, her body becoming a membranous cradle for the larvæ of the next generation, and after which she dies. From three to five generations of the cochineal insect may be produced in a single year. The first generation usually is richer in coloring matter and is considered the most valuable. It is estimated that from an area of about an acre of Nopal plants approximately 100 kilos of cochineal may be gathered; this would represent about 14,000,000 of the membranous cradles with larvæ, or the dried insects of commerce.

Description and Physical Properties.—"*Unground Cochineal.*—Somewhat ovate in outline, convex above, concave beneath, from 3.5 to 5 mm. in length, consisting of from 9 to 12 segments; externally grayish-purple or grayish; in the shell-like, somewhat horny abdomen lie numerous larvæ less than 1 mm. in diameter; the mature larvæ with 8-jointed antennæ, 3 pairs of legs, the lower having from 6 to 8 segments, and a characteristic beak or rostrum composed of 4 thread-like parts which pair off into 2 coils; easily pulverizable; odor characteristic; taste slightly bitter.

"*Powdered Cochineal.*—Dark red; odor, taste, and structure resembling the unground drug.

"The red color of dilute aqueous solutions of Cochineal is changed to purple with alkalies and to light orange with acids. When whole Cochineal is macerated in water, no insoluble powder separates." *U. S.*

"About five millimetres long; somewhat oval in outline, flat or concave beneath, convex above, transversely wrinkled, purplish-black or purplish-grey; easily reduced to powder, which is dark-red or puce-colored. Macerated in *water*, no insoluble powder is separated. Ash not more than 6 per cent." *Br.*

As found in commerce, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval, somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggist, distinguished by their external appearance. One is of a reddish-gray color, formed by an intermixture of the dark color of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada.* It is the variety commonly found in commerce. The other, *cochinilla renegrida,* or *grana nigra,* is dark-colored, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the names of *silver grains* and *black grains.* Some suppose the difference to arise from the mode of preparation, the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by hot water, which removes the external whitish powder; it is also said that cochineal is blackened by placing the insects with black sand in a bag and swinging backward and forward until some of the juice exudes. According to Faber, who derived his information from a merchant residing in the neighborhood where the cochineal is collected, the silver grains consist of the impregnated female just before she has laid her eggs; the black, of the female after the eggs have been laid and hatched. (*A. J. P.*, xviii, 47.) There is little or no difference in their quality. *Cake cochineal* and *grana sylvestra* are forms which have entirely disappeared from commerce, see *U. S. D.*, 20th ed., p. 365.

Composition.—Cochineal has a faint, heavy odor and a bitter, slightly acidulous taste. Its powder is of a purplish-carmine color, tingeing the saliva intensely red. According to Pelletier and Caventou, it consists of a peculiar coloring principle, a peculiar animal matter constituting the skeleton of the insect, stearin, olein, an odorous fatty acid, and various salts. Tyrosin has also been found by De la Rue, and its presence in cochineal confirmed later on by von Miller and Rohde. (*B. Chem. G.*, xxvi, 2660.) It was also analyzed by John, who called the coloring principle *cochinilin.* It is, however, universally known now as *carminic acid.* Hlasiwetz and Grabowski (*Ann. Ch. Ph.*, cxli, 329) gave it the formula $C_{17}H_{18}O_{10}$, and considered it to be a glucoside, which was decomposed by boiling with diluted sulphuric acid into a non-fermentable sugar and *carmine red,* $C_{11}H_{12}O_7$. The incorrectness of this view has, however, been demonstrated by von Miller and Rohde, who have shown that the purified carminic acid is a dioxymethyl-α-naphthoquinone of the formula $C_{12}H_{11}O_7$, or the double formula $C_{24}H_{22}O_{14}$, and that the carmine red is identical with it. Schunk and Marchlewski (*B. Chem. G.*, xxvii, 2979) have shown that the reason that the carminic acid as freshly extracted from the cochineal gave the apparent glucoside reaction was that it is impure. They prepared the pure crystallized carminic acid, its anilide, and identified its character as a naphthoquinone derivative. Their analysis indicated a composition of $C_{11}H_{12}O_6$. Still more recent work by Liebermann, Höring and Wiedermann (*B. Chem. G.*, 1900, xxxiii, 149) and indicates a formula of $C_{22}H_{22}O_{13}$. Dimroth and Karumerer believe carminic acid to be a derivative of oxyanthra-purpurin and assign the formula $C_{18}H_{20}O_{13}$. It shows no sharp melting point, beginning to decompose at 130° C. Carminic acid is of a brilliant purple-red color, unalterable in dry air, is very soluble in water, soluble in cold and more so in boiling alcohol, insoluble in ether. It may be obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposits a part of the carminic acid, and yields the remainder by spontaneous evaporation. It may be freed from a small proportion of adhering fatty matter by dissolving it in official alcohol and then adding an equal quantity of ether. The pure carminic acid is deposited in the course of a few days. Chlorine readily destroys the carminic acid, and nascent hydrogen reduces it to a leuco body, which again becomes red on exposure to the air.

The aqueous infusion of cochineal is of a violet-crimson color, which is brightened by the acids and deepened by the alkalies. The coloring matter is readily precipitated. The salts of zinc, bismuth, and nickel produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and the chloride, precipitate the coloring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes which have rendered cochineal so valuable in the arts. With alumina the coloring matter forms the pigment called *lake* (see *Carmina*).

Cochineal-carmine requires for its production a decoction of cochineal itself, and not of carminic acid, the nitrogenized matters being essential to its formation. Liebermann (*B. Chem. G.*, xviii, p. 1971) considers cochineal-carmine to be no ordinary compound of a coloring matter with alumina, but to be an alumina albuminate of the carmine coloring matter comparable in some respects to the product from alizarin and alumina with "Turkey-red oil." (See also *C. D.*, 1893, 199.)

Liebermann found that the coating of the silver cochineal consisted of a peculiar wax, which he named *coccerin,* $C_{30}H_{60}(C_{31}H_{61}O_3)_2$; this is soluble in benzene, but nearly insoluble in ether. (*P. J.*, 1885, 186.) J. J. Hess proved that if fatty matters found in cochineal were removed by treatment with alcohol, a much more brilliant carmine could be produced. (Dingler, *P. J.*, lxxxviii, 235.) The degree of coloring power in cochineal may be approximately measured by the decolorizing effect produced by solution of potassium permanganate. For a method of applying this process, the reader is referred to a paper by J. M. Merrick, of Boston, in *A. J. P.*, 1871, 263. The Pharmacopœias require that when cochineal is macerated in water no insoluble powder shall be separated, and that when incinerated with free access of air it shall yield not more than 6 per cent. of ash.

Cochineal may be detected when used as a coloring reagent by acidulating the suspected solution with hydrochloric acid, agitating with amyl alcohol, separating the latter solvent and shaking it with an aqueous solution of uranium acetate. Cochineal shows a violet color in the aqueous layer and carmine a green color.

Cochineal has been adulterated by causing certain heavy substances, such as powdered talc, lead carbonate, and barium sulphate, by shaking in a bag or otherwise, to adhere, by means of some glutinous material, to the surface of the insects, and thus increase their weight. This fraud is detectable either by a high percentage of ash or by microscopic examination which shows the absence of a woolly appearance which characterizes the white powder upon the surface of the unadulterated insect. (For other adulterants formerly encountered see *U. S. D.*, 20th ed., p. 366.)

The importations of cochineal have diminished, owing to the gradual replacement of this dye by the newer coal-tar colors.

The commercial supplies used in the United States come chiefly from Teneriffe, an island of the Canaries, and from Mexico.

Uses.—Cochineal was at one time supposed by some to possess anodyne properties, and used in *whooping-cough* and *neuralgia*. At present it is employed only as a coloring agent.

COCILLANA. N. F.

COCILLANA Cocillan. [Guapi Bark]

"Cocillana is the dried bark of *Guarea Rusbyi* (Britton) Rusby (Fam. *Meliaceæ*). Cocillana contains not more than 5 per cent. of wood or other foreign organic matter." *N. F.*

Cocillana Bark, Huapi Bark, Trompillo.

The plant yielding Cocillana is a tree indigenous to the upper slopes of the eastern Andes in Bolivia. It possesses leaves which are paripinnate with a bud at the top of the rachis between the last pair of leaflets. Its fruits are pear-shaped when young, becoming nearly spherical when ripe. The bark of this tree was long used by the aborigines of the Andes as an emetico-cathartic. Its use in this country is largely due to its introduction by Dr. H. H. Rusby who, in 1886, first collected it at Guanai, a town on the Mapiri River and for a number of years thereafter was the sole importer in the United States. Since 1908 a substitute Cocillana bark has frequently appeared on the market. The tree yielding this bark is *Guarea Bangii* Rusby as determined by H. H. Rusby who collected specimens in October, 1921, from trees growing at Rurrenabaque, Bolivia. (For description of trees yielding this substitute bark and possible future substitutes see *Bull. Torrey Bot. Club,* 1922, xlix, p. 262.) This substitute may be distinguished from the genuine article by the more reddish cast of its cork, its tougher and more fibrous fracture, the fibers projecting throughout the middle and inner bark, by its smaller stone cells and less numerous crystals. The powdered bark is light chocolate brown whereas that of the genuine article is grayish-brown. (Ballard, *A. Ph. A.,* 1922, xi, p. 781–787.)

Description and Physical Properties.—"*Unground Cocillana.*—In flat or curved pieces of variable length and width up to about 2 cm. thick; outer surface shallowly or deeply fissured, according to age and thickness; gray-brown, often ashy-gray from lichen growths, or of an orange-brown where the cork has been removed; inner surface of medium brown color, strongly and coarsely longitudinally striate, the striæ straight or wavy; inner bark usually much thicker than the outer, its fracture coarsely splintery-fibrous and soft. Odor characteristic; taste slightly astringent, peculiar and slightly nauseous.

"*Structure.*—Outer bark composed of one or more zones of cork alternating with layers composed of parenchyma and isolated stone cells; middle bark composed of starch-containing parenchyma, groups of thick-walled stone cells, and a few bundles of fibers; inner bark with large groups of yellow fibers, surrounded by crystal fibers and separated tangentially by parenchyma and sieve tissue, and radially by wavy medullary rays 1 to 3 cells in width, the latter with porous walls and frequently lignified; many of the medullary ray cells contain reddish amorphous masses, and occasionally starch grains; secretory cells in the middle and inner bark containing a yellowish white granular substance.

"*Powdered Cocillana.*—Light brown; numerous groups of lignified fibers, the individual fibers up to 0.800 mm. in length with nearly straight walls and attenuated ends; crystal fibers, showing prisms of calcium oxalate mostly from 0.010 to 0.025 mm. in length; parenchyma and medullary ray cells with reddish brown contents or starch grains, the latter single and spheroidal, or 2-4 compound, the individual grains measuring from 0.005 to 0.020 mm. in length; stone cells abundant, yellowish, with thick porous walls, angular to irregular in shape, up to 0.150 mm. in length. Many fragments of dark brownish cork tissue." *N. F.*

Cocillana contains a small quantity of an alkaloid, about 2.5 per cent. of resin, 2.5 per cent. of fixed oil and a white crystalline hydrocarbon, melting at 80° C., sublimable with a peculiar aromatic odor.

Uses.—In *doses* of from twenty to fifty grains (1.3–3.2 Gm.) the bark causes vomiting, with prostration and some purging; also, it is said, much sneezing, dull frontal headache, and discharge from the nasal mucous membrane. The therapeutic action of the drug resembles that of ipecac, although as an expectorant it is somewhat more stimulant. (See *N. Y. M. J.,* Dec., 1889, and April, 1890). It has been used in various forms of *bronchitis* with asserted success.

Dose, eight to fifteen grains (0.5–1.0 Gm.).

Off. Prep.—Fluidextractum Cocillanæ, *N. F.*

CODEINA. U. S., Br.

CODEINE Codein. [Methylmorphine]

"An alkaloid [$C_{17}H_{18}(CH_3)O_3N.H_2O$ = 317.19] obtained from opium, or prepared from morphine by methylation." *U. S.* "Codeine, $C_{18}H_{21}NO_3,H_2O$, is an alkaloid obtained from opium or prepared from morphine." *Br.*

Codeia, Methylmorphine; Codeinum, Codéine, *Fr. Cod.;* Codein, Kodein, *G.;* Codeina, *It., Sp.*

Preparation.—*Codeine* was discovered in 1832 by Robiquet in morphine hydrochloride prepared according to the process of Gregory. It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochloride. (See *Morphina.*) When the solution of the mixed morphine and codeine hydrochlorides is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeine in colorless crystals on spontaneous evaporation. Codeine is the methyl derivative of morphine, as shown in the formula $C_{17}H_{18}(CH_3)O_3N$. It may be formed artificially from morphine by treating this latter successively with methyl iodide and fixed alkali. (Grimaux, 1881, *J. Chem. S.*, xliv, 358.) Codeine may be made also by the following process: Morphine, 285 Gm., and nitrosomethylurethane, 132 Gm., are dissolved in 1 kilo. of methyl alcohol. With the solution is mixed, constantly stirring, a solution made by mixing 50 Gm. of potassium hydroxide in 800 Gm. of methyl alcohol. When the reaction is complete, the methyl alcohol is distilled off, and codeine is extracted from the residue with benzene, from which it afterwards separates in characteristic crystals. (*C. D.*, 1898, 237.)

Description and Physical Properties.—"Colorless, translucent crystals, or a white, crystalline powder. It is odorless, and is slightly efflorescent in warm air. One Gm. of Codeine is soluble in 120 cc. of water, 2 cc. of alcohol, 0.5 cc. of chloroform, 18 cc. of ether, and in 13 cc. of benzene, at 25° C. One Gm. is soluble in 1.2 cc. of alcohol at 60° C.

"When heated in an amount of water insufficient for complete solution, Codeine melts to oily drops, which crystallize on cooling. Codeine rendered anhydrous by drying at 80° C. melts between 154° and 156° C. A saturated, aqueous solution of Codeine is alkaline to litmus paper, and is lævorotatory. Sulphuric acid, containiny 0.005 Gm. of selenous acid in each cc. produces with Codeine a green color, which changes rapidly to blue, then slowly back to green. Dissolve about 0.01 Gm. of Codeine in 5 cc. of sulphuric acid, add a drop of ferric chloride T.S., and warm: the solution becomes blue, changing to red on the addition of a drop of nitric acid.

"When dried to constant weight at 80° C., Codeine loses not more than 6 per cent. of its weight (*water*). The ash from 0.5 Gm. is negligible. About 0.01 Gm. of Codeine dissolves in 5 cc. of sulphuric acid (free from nitrous compounds without producing other than a transient, pinkish tint (*readily carbonizable substances*). Dissolve about 0.05 Gm. of potassium ferricyanide in 10 cc. of distilled water, add 1 drop of ferric chloride T.S. and 1 cc. of a neutral or slightly acid, aqueous solution of Codeine (1 in 100) made with the aid of sulphuric acid: no blue color is produced at once (*morphine*).

"Preserve in well-closed containers, protected from light." *U. S.*

"Colorless or nearly colorless crystals. Soluble in 80 parts of *water,* and in 80 parts of *solution of ammonia,* readily soluble in *alcohol* (90 per cent.), and in *chloroform.* The aqueous solution has a bitter taste and an alkaline reaction. Melting point 155° to 156° C. 0.1 gramme dissolves in 1 millilitre of cold *sulphuric acid* without coloration or with the production at most of a faint pink tinge; but when the solution is gently warmed with a trace of *ammonium molybdate* or of *ferric chloride* a deep bluish-violet color is developed which, on the addition of a drop of *diluted nitric acid,* changes to scarlet and finally orange. When a little of the powdered alkaloid is sprinkled on *nitric acid* the liquid becomes yellow but not red (distinction from morphine). A saturated aqueous solution, acidified with *hydrochloric acid,* gives no blue color, but only gradually a dull green, on the addition of diluted *T. Sol. of ferric chloride* and very dilute *solution of potassium ferricyanide* (absence of morphine). A solution (1 in 50) in *water* acidified with *hydrochloric acid* yields a white precipitate with *solution of sodium hydroxide* but not with *solution of ammonia.*" *Br.*

When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It may be separated from morphine by a solution of potassium or sodium hydroxide, which dissolves the morphine and leaves the codeine. It has an alkaline reaction on test paper, and combines with acids to form salts, some of which are crystallizable. Its capacity of saturation is almost identical with that of morphine. According to Robiquet, 1 part of hydrochloric acid is saturated by 7.837 of codeine, and by 7.88 of morphine. It is distinguishable, however, from the latter principle by the different form of the crystals, which are octahedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red color with nitric acid, or a blue one with ferric salts. Tincture of galls precipitates from its solutions a codeine tannate. Crystallized from an aqueous solution, it contains about 6 per cent. of water, which is driven off at 100° C. The crystals obtained from a solution in ether contain no water.

Uses.—Codeine resembles morphine in its general physiological action. Von Schroeder (*A. E. P. P.*, 1883, xvii) has shown that it heightens the reflex activity of the spinal cord. It also exerts a depressant effect on the higher cerebral centers; Macht (*J. P. Ex. T.*, 1916, viii, p. 1) has shown that it lowers the threshold of pain perception, the efficient dose being approximately 3 or 4 times as large as that of morphine. Its sedative action upon the respiratory center is similar in type to that of morphine, although it requires, according to the observations of Macht (*J. P. Ex. T.*, 1915, viii, 339), almost ten times as much codeine as it does morphine to produce a corresponding effect.

Like morphine it also tends to increase the tone of unstriped muscle tissue (Macht, *J. P. Ex. T.*, 1918, xi, 389). Its narcotic action differs in type from that of morphine, especially in the fact that it is much less likely to give rise to habit.

It has been highly lauded in the treatment of *diabetes mellitus,* and cases of recovery under its use reported. In the grave form of this disorder we have seen it fail to exert any perceptible influence, but the evidence is sufficient to demand a fair trial of the remedy in any individual case. Medical practitioners often use it to quiet *cough,* to allay *intestinal pain,* and to fulfil various other of the minor narcotic indications for which opium is commonly administered. Although less efficient than morphine it has the advantage of being less constipating and less liable to habit formation. On account of its frequent contamination with morphine, care should be exercised as to the commencing dose, but no marked effect is to be expected, if the alkaloid be pure, from less than one grain (0.065 Gm.), and this dose may be rapidly increased until some symptoms are produced. It may be given in pill or in syrupy solution.

The symptoms of codeine *poisoning* in man differ considerably from those of morphine. There is usually narcosis, sometimes preceded by a feeling of exhilaration and followed by convulsions. In most of the reported cases nausea and vomiting have been prominent symptoms and there has also been evidence of circulatory depression. The pupils are contracted, the pulse rate usually increased. We are not familiar with any case of fatal codeine poisoning, but alarming symptoms have followed the ingestion of 4 grains (Myrtle, *B. M. J.*, 1874), and Boissonnas (*R. M. S. R.*, 1919, xxxix, 581) reports a case of violent poisoning in a child of 3 years from 0.04 Gm. ($\frac{3}{5}$ of a grain). The treatment of codeine poisoning should be along the same lines as that of morphine poisoning.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

Off. Prep.—Elixir Terpini Hydratis et Codeinæ, *N. F.*

CODEINÆ PHOSPHAS. U. S., Br.

CODEINE PHOSPHATE Codein. Phos.

"Codeine Phosphate [$C_{17}H_{18}(CH_3)O_3N.H_3PO_4.2H_2O$] contains not less than 67 per cent of anhydrous codeine ($C_{17}H_{18}(CH)_3O_3N$)." *U. S.* "Codeine Phosphate, $C_{16}H_{21}NO_3,H_3PO_4,2H_2O$, is the phosphate of the alkaloid codeine." *Br.*

Phosphate de Codéine, *Fr.;* Codeïnum phosphoricum, *P. G.;* Kodeinphosphat, Phosphorsaures Kodein, *G.*

This salt has been introduced because of its easy solubility and stability; it may be made by dissolving 1 part of codeine in 1.25 parts of 25 per cent. phosphoric acid (the solution should be slightly acid in reaction); sufficient alcohol is added to precipitate the codeine phosphate. On account of its large percentage of codeine (about 70 per cent.) it is well fitted for hypodermic injections.

Description and Physical Properties.—"Fine, white, needle-shaped crystals, or a white, crystalline powder. It is odorless. Codeine Phosphate readily loses water on exposure to air. One Gm. of Codeine Phosphate is soluble in 2.3 cc. of water, 325 cc. of alcohol, 4500 cc. of chloroform, and in 1875 cc. of ether, at 25° C. One Gm. is soluble in 0.5 cc. of water at 80° C., and in 125 cc. of boiling alcohol.

"An aqueous solution of Codeine Phosphate (1 in 20) is acid to litmus paper. It responds to the identity tests with selenous acid, ferric chloride and nitric acid under *Codeina.* In an aqueous solution of Codeine Phosphate neutralized with ammonia water, silver nitrate T.S. produces a yellow precipitate, which is soluble in diluted nitric acid and in ammonia water.

"Separate portions of 10 cc. each of an aqueous solution of Codeine Phosphate (1 in 100) show no turbidity at once on the addition of a few drops of barium chloride T.S. (*sulphate*), and no opalescence with a few drops of silver nitrate T.S. (*chloride*). Codeine Phosphate complies with the test for *morphine* under *Codeina.*

"**Assay.**—Dissolve about 0.5 Gm. of Codeine Phosphate, accurately weighed, in 10 cc. of distilled water, in a separator, add 10 cc. of sodium hydroxide T.S., and extract the codeine by shaking with four successive portions of 15 cc., 10 cc., 10 cc., and 5 cc. of chloroform, or a sufficient quantity to complete the extraction. Shake the combined chloroform solutions with 5 cc. of distilled water, and completely separate the chloroform from the aqueous layer. Evaporate the chloroform almost to dryness on a water bath, dissolve the residue by warming with 15 cc. of tenth-normal sulphuric acid, heat the solution on the water bath until the odor of chloroform is no longer evolved, cool, dilute with about 10 cc. of distilled water, and titrate the excess of acid with tenth-normal sodium hydroxide, using 2 drops of methyl red T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.02993 Gm. of anhydrous codeine ($C_{18}H_{21}O_3N$).

"Preserve in well-closed containers, protected from light." *U. S.*

"White efflorescent crystals. Taste slightly bitter. Soluble in 3.5 parts of *water.* An aqueous solution (1 to 20) has a slightly acid reaction and yields a white precipitate with *solution of sodium hydroxide,* but not with *solution of ammonia.* Loses its water of crystallisation at 100° C. Yields the *reactions* characteristic of phosphates, and responds to the color-tests described under 'Codeina.'" *Br.*

Uses.—The medicinal properties of codeine phosphate are the same as those of codeine.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

Off. Prep.—Syrupus Codeinæ Phosphatis, *Br.*

CODEINÆ SULPHAS. U. S.

CODEINE SULPHATE Codein. Sulph.

"$[C_{17}H_{18}(CH_3)O_3N]_2H_2SO_4.5H_2O$." *U. S.*

Codeinum sulfuricum; Sulfate de Codéine, *Fr.;* Kodein ulfat, Schwefelsaures Kodein, *G.*

Preparation.—Codeine sulphate may be made by dissolving codeine in warm water, adding sufficient sulphuric acid to neutralize, evaporating and crystallizing; 16.71 Gm. of sulphuric acid of official strength will be required to neutralize 100 Gm. of codeine.

Description and Physical Properties.—"Long, glistening, white, needle-shaped crystals or rhombic prisms, or a crystalline powder. It is odorless, and is efflorescent in the air. One Gm. of Codeine Sulphate is soluble in 30 cc. of water and in 1280 cc. of alcohol, at 25° C. One Gm. is soluble in 6.5 cc. of water at 80° C. and in 440 cc. of alcohol at 60° C. It is insoluble in chloroform and in ether. It responds to the identity tests with selenous acid, ferric chloride and nitric acid under *Codeina.* Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate which is insoluble in hydrochloric acid.

"When dried to constant weight at 100° C., Codeine Sulphate loses not more than 12 per cent. of its weight (*water*). The ash from 0.5 Gm. is negligible. A solution of 0.5 Gm. of Codeine Sulphate in 15 cc. of distilled water requires not more than 0.3 cc. of fiftieth-normal sodium hydroxide for neutralization, using one drop of methyl red T.S. as indicator. Codeine Sulphate complies with the tests for *morphine* and *readily carbonizable substances* under *Codeina.*

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—The medicinal properties of this salt are those of the alkaloid codeine.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

COFFEA TOSTA. N. F.

COFFEE Coff. Tost. [Roasted Coffee]

"Coffee is the dried ripe seed of *Coffea arabica* Linné or *Coffea liberica* Bulliard (Fam. *Rubiaceæ*), deprived of most of the seed coat and roasted until a dark brown color and characteristic aroma are developed. Coffee yields not less than 1 per cent. of caffeine, not less than 3 per cent. and not more than 5 per cent. of total ash, and not less than 10 per cent. of fat." *N. F.*

Coffee, Semen Caffeæ; Kaffee, *G.;* Café, *Fr.;* Caffe, *It.;* Café, *Sp.;* Bun, *Ar.;* Copi Cotta, *Cingalese;* Kaeva, *Malay.*

Coffea arabica L. and *C. liberica* Bull. are small evergreen trees with opposite, oblong-ovate, acuminate leaves of leathery texture, axillary clusters of white, tubular flowers and globular, red to purplish, berry fruits. The coffee berries are about the size of a cherry. Each of these consists of a 2-celled pericarp surrounding 2 plano-convex seeds. The seeds are longitudinally grooved on their plane surfaces and enveloped by a thin membranous endocarp called "parchment." Between each seed and the parchment is a thin covering called "silver-skin." When divested of their coverings they constitute coffee. *Coffea arabica* is indigenous to Abyssinia, while *C. liberica* is native to Liberia. *C. robusta* has recently been cultivated in Java. For description see Vichoever and Lepper (*J. Assoc. Off. Agr. Chem.,* 1921, v, 274).

About the year 1690 coffee was introduced by the Dutch from Arabia into Java, and in 1718 into their colony of Surinam. Soon after this latter period the French succeeded in introducing it into their West India islands, Cayenne, and the Isles of France and Bourbon. Within a comparatively short time coffee cultivation was taken up by many other tropical countries of the western hemisphere.

To-day the coffee plants are extensively cultivated in Arabia, Java, South America, Central America, Mexico, West Indies, India and Hawaii. Brazil and Java are the largest producers, Brazil giving to the world about 80 per cent. of all the coffee produced.

The coffee trees are grown from seeds which, when sown in properly prepared soil, germinate in less than a month. Within a year the young plants are transplanted and set out at suitable distances. They yield mature fruits in two or three years but generally require five years before bearing a good crop and continue to be productive for thirty to thirty-five years. Two crops are generally harvested each year. The fruits are gathered when fully mature and prepared for the market by either the dry or wet methods.

The dry method is the more primitive and at present almost restricted to Arabia which yields much of the Mocha coffee. It consists of spreading the fruits out in a thin layer on a drying floor and exposing them to the drying action of the sun. Later the pulp and parchment are removed, liberating the two seeds contained in each fruit. In the wet or West Indian method which is the one now most generally employed, the fruits are placed in a tank of water. The mature fruits sink and are drawn through pipes to a pulping machine where the fleshy portion is reduced to a pulp, and the pulp and free seeds, enclosed in their membranes, conveyed to a second tank of water. Here they are stirred, the pulp being separated by washing and the seeds sinking to the bottom. The parchment membranes are removed by allowing them to slightly ferment and by washing, accompanied by trampling with bare feet and stirring. The seeds are then dried in trays, or barbecues, by natural or artificial heat. In this condition they constitute "raw coffee." They are subsequently graded by passing them through sieves having large, medium and small apertures. They are then garbled to remove split or otherwise defective seeds and foreign matter. They are usually packed in bags and imported in the unroasted condition.

The finest coffee grown is that commercially known as "Java coffee" from the East Indies, mostly from Sumatra. *Mocha* coffee is a sharp, aromatic type which is grown in Arabia; little of it comes to this country. The chief varieties or types of coffee grown in Brazil are those designated commercially as "Santos Rio," "Mocha Seed Santos" and "Victoria."

Raw coffee has a faint, peculiar odor and a slightly sweetish, somewhat harsh taste.

During the roasting process coffee swells to almost double its original volume, losing from 15 to 23 per cent. of its weight, and acquires a new, peculiar odor and a bitter taste. An active empyreumatic oil (*caffeol,* $C_8H_{10}O_2$) is developed during the process, probably at the expense of a portion of the caffeine. Much of the alkaloid, however, escapes change, and a portion of it is volatilized. The excellence of the flavor of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When they have acquired a chestnut-brown color, the process should cease. If too long continued, it renders the coffee bitter and acrid, or, by reducing it to charcoal, deprives it entirely of flavor. During a severe roasting the coffee loses a portion of caffeine, which sublimes, while in a slight roasting it loses none; yet ordinary coffee for drinking, prepared by percolation, contains rather more caffeine when prepared from strongly roasted than from slightly roasted coffee, because the caffeine is more easily extracted from the former. Paul and Cownley found in preparing "low and medium roasted" coffee no perceptible loss of alkaloid, while in "over-roasted" coffee the loss amounted to one-third. The average of caffeine in roasted coffee they give as at 1.3 per cent. (*P. J.*, 1887, 822.)

Parry (*Food and Drugs,* vol. i, 1911, p. 31) gives the following comparative figures for coffee before and after roasting:

	Raw (per cent.)	Roasted (per cent.)
Moisture	11.90 to 12.45	3.7 to 4.1
Ash	3.66 to 3.72	3.82 to 3.95
Cellulose	26.82 to 28.5	25.00 to 26.8
Caffeine	1.2 to 1.36	1.36 to 1.40
Sugar	3.2 to 4.0	1.1 to 1.5

Seissir has devised a method for removing the caffeine from coffee. About 5 kilos of unroasted coffee berries are placed in a closed centrifugal drum which is surrounded by a hot-water jacket. After the addition of about 15 kilos of ethyl acetate, the drum is set in motion, so that the solvent and berries are thoroughly mixed, the temperature being maintained at 68° C. At the end of three hours the solvent is drawn off, and replaced by a further quantity of about 10 kilos, and the mixing and extraction are continued for a further two hours. The ethyl acetate is then run off, the berries are heated to 100° C. to remove the last traces of solvent, and finally dried at 40° to 46° C., the drum being rotated meanwhile. The ethyl acetate may be recovered by distillation, and the caffeine separated from the residue. The method is the subject of a French patent. (*J. Soc. Chem. Ind.*, 1909, 622.)

Description and Physical Properties.—"*Unground Coffee.*—Oval, of variable size, having one side strongly convex, the other flat with a longitudinal groove, and showing traces of the papery seed coat in the cleft. It has a characteristic aroma and a pleasantly bitter taste.

"*Powdered Coffee.*—Numerous fragments of the seed coat made up of parenchyma and irregular stone cells, the latter up to 1.000 mm. long and up to 0.135 mm. wide, with walls having simple pores; numerous brownish endosperm cells having porous walls about 0.010 mm. thick and containing oil and aleurone grains; starch grains few or absent; reticulate tracheæ wanting.

"Percolate 1 Gm. of powdered Coffee with ether until exhausted and evaporate the percolate to dryness; the residue weighs not less than 0.1 Gm. (presence of at least 10 per cent. of fat). Boil 1 Gm. of powdered Coffee with 10 cc. of distilled water, filter and acidify the filtrate with 1 cc. of diluted sulphuric acid, and then decolorize it by the cautious addition of potassium permanganate T.S. This decolorized solution shows no blue or purple coloration upon the addition of iodine T.S. (*starch*) Shake 1 Gm. of Coffee with 20 cc. of water; the strained liquid shows no colored or heavy deposit. Shake 1 Gm. of Coffee with 20 cc. of alcohol; the strained liquid shows no colored or heavy deposit nor is any color imparted to the alcohol (*artificial colors or facings*).

"**Assay.**—Place 6 Gm. of Coffee, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see *Proximate Assays,* Type Process A) during two hours. Allow the mixture to stand over night, again shake intermittently during one-half hour, then allow the drug to settle. Decant or filter off through a pledget of purified cotton, 100 cc. of the chloroformic liquid, representing 5 Gm. of Coffee, and evaporate to dryness. Treat the residue with 10 cc. of weak (about 1 per cent.) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, and wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate strongly with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus, and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Coffee." *N. F.*

Adulterations.—Both whole and ground roasted coffee have been and still are adulterated by irresponsible dealers. The whole article has been adulterated with artificial coffee seeds made by moulding and roasting dough as well as masses of pea hulls, ground cereals and molasses. The ground article has been adulterated with the following ground roasted materials: chicory root, identified by its short, pitted and reticulate tracheæ from 25 to 50 μ in breadth and numerous laticiferous vessels; dandelion root, identified by its pitted and reticulate tracheæ up to 80 μ in width and numerous laticiferous vessels; cereals and cereal products, identified by their hairs, cross cells and starch grains; coffee hulls, characterized by a layer of curved palisade cells with yellowish contents; leguminous seeds, characterized by fragments of palisade cells and typical starch grains; figs, identified by fragments of the mesocarp of receptacle containing abundant branching latex tubes up to 50 μ in breadth, and numerous rosette crystals of calcium oxalate and by numerous small achenes usually imbedded in the roasted pulp; ivory nuts, identified by the large, endosperm cells with porous walls of reserve cellulose that are up to 35 μ or more in thickness; acorn kernels, identified by their distorted, ellipsoidal or elongated starch grains, each with prominent elongated hilum.

Chicory, dandelion and other similar roots used as adulterants may be detected microscopically, but a chemical method of detection has been proposed by LaWall and Forman (*J. A. Ph. A.*, 1914, iii, p. 1669), which depends upon the determination of the ratio of reducing sugars to extractive matter in the aqueous decoction.

Mussaenda coffee, so called, is not a true coffee, but the seeds of *Gaertnera vaginata* Lam. (Fam. *Loganiaceæ*). (*P. J.*, Nov., 1889.)

C. Griebel (*Nahr. Genussm,* 1918, xxxv, 272) finds among the numerous coffee substitutes chicory and beets play the main rôle. In addition, however, waste products have been used, like potato pulp, husks of grapes or other fruits, tree bark, the stony part of fruit shells and kernels or stone fruits of plants such as hawthorne, rose, etc. Spurry as well as locust seeds (see *Robinia,* Part II) have been used as coffee substitutes, and Griebel discusses them in detail. Spurry (*Spergula arvensis,* Fam. *Caryophyllaceæ*), growing quite generally as a weed on sandy soil, is under cultivation for feed in western Germany.

Constituents.—The most important substances present in raw coffee are: the alkaloid caffeine, a peculiar tannin, and a sugar, probably glucose, which is almost completely caramelized in the roasting process. *Caffetannic acid* has been ascertained by Hlasiwetz to be a glucoside with the formula $C_{14}H_8O_7$ and resolvable into glucoside and a peculiar crystallizable acid, $C_8H_8O_4$, named by him *caffeic acid* (*J. P. C.*, 1867), and which may be obtained from coffee by boiling a solution of the extract with potassium hydroxide, treating the resulting liquid with sulphuric acid in excess, and extracting the caffeic acid with ether, which yields it somewhat impure by evaporation. (*J. P. C.*, 1868, 75.) Caffeic acid has the constitution of a dihydroxy-cinnamic acid, and on fusion with potassium hydroxide yields protocatechuic and acetic acids. The *coffee fat,* which ranges in different varieties from 14 to 21 per cent., is, when purified, white, without odor, of a buttery consistence, melting at 37.5° C., and becomes rancid on exposure. According to Rochleder (*Wien. Akad Ber.*, xxif, 40), it contains glycerides of palmitic acid and of an acid of the composition $C_{12}H_{24}O_2$.

The caffeine, according to Payen, is present partly free and partly as a *potassium and caffeine chlorogenate,* but H. Gorter (*Ann. Ch.*, ccclix, 217, ccclxii, 237), in investigations made upon Liberian coffee, stated that caffeine does not exist free in coffee, but is all combined. The compound is given the following formula: $C_{32}H_{36}C_{19}K_2(C_8H_{10}O_{12}N_4)_2 + 2H_2O$. It decomposes at 225° C., without melting. The salt is scarcely decomposed by dry chloroform, but is easily decomposed by the presence of water and then gives up its caffeine. This explains the fact observed by the manufacturers of decaffeinated coffees, that dry coffee yields only a small amount of its caffeine to chloroform, but that the extraction takes place readily and almost completely if the coffee is simultaneously treated with water or steam.

Chlorogenic acid is given the formula, $C_{32}H_{38}O_{19}$, and is a colorless, crystalline compound, melting at 206° C., and with a marked lævorotatory power. It is hydrolyzed by alkalies into caffeic and quinic acids. When strongly heated it emits an odor of roasted coffee and by some is believed to be the principle to which the flavor of the beverage is to be attributed. It is stated that when acted on by sulphuric acid and manganese dioxide it is converted into quinone, being in this respect analogous to quinic acid. Another acid was found which the author named *coffalic acid.* The coffee also contained citric acid, trigonelline, a pectin and an oxydase.

Julian E. Walter (*Ph. Rec.*, May 5, 1890, 176) found the percentage of caffeine in various samples of unroasted coffee to range from 0.54 to 1.24 per cent. Bertrand (*Bull. Sc. Pharm.*, iv) gives the following results of studies of the percentage of caffeine in various coffee berries: In *Coffea arabica* the percentage varied from 0.69 to 1.60; *C. canephora* was found to be rich in alkaloid, the berries yielding 1.97 per cent., while those of the *C. humboldtiana,* Baill., were remarkable by reason of their containing a bitter principle, *cafamarin,* but no caffeine at all; the berries of *C. mauritiana* contained only 0.07 per cent.

The *leaves* of the coffee plant possess properties analogous to those of the fruit, and are extensively used by the Malays. Stenhouse found them to contain caffeine in larger proportion than the coffee bean, and also caffeic acid. The leaves are prepared for use by drying over a clear fire and then powdering by rubbing in the hands. The powder is made into an infusion like common tea. The taste is like that of tea and coffee combined. (*P. J.*, xii, 443; xiii, 207 and 382, and xvi, 1067.)

The effects of coffee are due chiefly, if not solely, to the caffeine which it contains. Some writers, however, believe that the volatile oil, *caffeol* (*caffeone*) possesses stimulating properties. The evidence of this point, however, is so contradictory as to render conclusions impossible. (See Reichert, *M. News*, 1890, lvi; Erdmann, *A. E. P. P.*, 1902, xlviii; Geiser, *A. E. P. P.*, liii, p. 112.)

Uses.—As a medicine coffee has been almost entirely replaced by the alkaloid caffeine. The infusion is, however, sometimes administered by rectal injection in cases of narcotic poisoning. The chief reason for the recognition as a drug is its agreeable flavor. The disturbances of digestion which follow excessive coffee drinking are not considered by J. Burmann to be due to caffeine, but to a volatile toxic substance formed during roasting and only partly volatilized, named *cafeotoxin,* which can be eliminated by subjecting roasted coffee to successive treatments with steam under pressure of several atmospheres (*J. P. C.*, 1913, 8, 281.)

Dose, thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Coffeæ, *N. F.*

COLCHICI CORMUS. U. S., Br.

COLCHICUM CORM Colch. Corm. [Colchici Radix, U. S. 1890, Colchicum Root]

"Colchicum Corm is the dried corm of *Colchicum autumnale* Linné (Fam. *Liliaceæ*). Colchicum Corm yields not less than 0.35 per cent. of colchicine." *U. S.* "Colchicum Corm is the fresh corm of Colchicum autumnale, *Linn.*, collected in early summer; or the same deprived of its coats, sliced transversely, and dried at a temperature not exceeding 65° C." *Br.*

Colchicum autumnale, often called *meadow saffron,* is a perennial plant, the leaves of which appear in spring, and the flowers in autumn. Its underground portion consists of an ovoid corm. Its manner of growth is peculiar, and deserves notice as connected in some measure with its medicinal efficacy. In the latter part of summer, a new *corm* begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom and embraces it half round. The new plant sends out roots from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale-purple color, emerge from the spathe, unaccompanied by leaves. The corolla consists of a tube from 10 to 12 cm. long, concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground until the following spring, when they rise upon a stem above the surface, in the form of a three-lobed, three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about 12 cm. long, and 2.5 cm. broad at the base. In the meantime, the new corm has been increasing at the expense of the old one, which, having performed its appointed office, perishes; while the former, after attaining its full growth, sends forth shoots, and in its turn decays. The old corm in its second spring, and a little before it perishes, sometimes puts forth one or more small corms, which are the sources of new plants. The usual method of propagating colchicum is by planting the bulbs about August or September in deep rich soil, about 2 or 3 inches below the surface and about 3 inches apart in the row. (*D. C.*, 1912, p. 134.) Most of the commercial supplies of the drug are imported from Leghorn, Italy and Amsterdam, Holland.

C. autumnale is a native of the temperate parts of Europe and of Northern Africa, growing in moist pastures and meadows. Attempts have been made to introduce its culture into this country, but with no great success, though small quantities of the corm, of apparently good quality, have entered commerce. The flowers possess virtues similar to those of the corm and are recognized by the French Codex.

Colchici Cormus.—The medicinal virtue of the corm depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties, and late in the fall it has become exhausted by the nourishment afforded to the new plant. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of

August, when the offset appears. It may be owing, in part, to this inequality at different seasons that entirely opposite reports have been given of its powers. Krapf ate whole corms without inconvenience; Haller found them entirely void of taste and acrimony, and we are told that in Carniola the peasants use them as food with impunity in the autumn. On the other hand, there can be no doubt of its highly irritating and poisonous nature, when fully developed, under ordinary circumstances. Perhaps soil and climate may have some influence in modifying its character.

Christison found the roots collected in April to be more bitter than those gathered in July, and conjectures that the common opinion of their superior efficacy at the latter season may not be well founded. Schroff states, as the result of his observation, that the autumnal root is much stronger than that dug in the summer. (See *A. J. P.*, xxix, 324.)

The corm is often used in the fresh state in the countries where it grows, it is apt to be injured in drying, unless the process is carefully conducted. The usual plan is to cut the corm, as soon as possible after it has been dug up, into thin transverse slices, which are spread out separately upon paper or perforated trays and dried with a moderate heat. The reason for drying it quickly after removal from the ground is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life that, if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. Houlton recommends that the corm be stripped of its dry coating, carefully deprived of the bud or young bulb, and then dried whole. It is owing to the high vitality of the bud that the corm is so apt to vegetate. During desiccation there is great loss of weight, 70 per cent. being the average for a number of years in the laboratory of Allen & Hanbury, in London.

The recent corm of *C. autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white and fleshy, and, when cut transversely, yields, if mature, an acrid milky juice. There is often a small lateral projection from its base, which is the bud for the development of a new plant; this bud is frequently broken off in drying. When dried, and deprived of its external membranous covering, the corm is of an ash-brown color, convex on one side, and somewhat flattened on the other, where it is marked by a deep groove extending from the base to the summit. As found in commerce, it is always in the dried state, sometimes in segments made by vertical sections of the corm, but generally in transverse, reniform or longitudinal ovate slices.

Description and Physical Properties.—"*Unground Colchicum Corm.*—Usually in reniform transverse slices or in ovate longitudinal slices from 2 to 5 mm. in thickness; flat surfaces whitish, slightly roughened, and of a crystalline appearance under a hand lens; epidermal surface light brown and finely wrinkled; fracture short and mealy; odor slight; taste bitter and acrid.

"*Powdered Colchicum Corm.*—Light brown or grayish-brown; starch grains numerous, single or 2- to 6-compound, the individual grains varying from spherical or ovoid to polygonal, from 0.003 to 0.030 mm. in diameter and marked with a triangular or star-shaped central cleft; tracheæ few and with spiral or scalariform thickenings; occasional fragments of epidermal cells with thin, reddish-brown walls.

"**Assay.**—Proceed as directed under *Colchici Semen.*" *U. S.*

"Fresh corm about thirty-five millimetres long and twenty-five millimetres broad, somewhat conical, hollowed on one side where a new corm is in process of development, and rounded on the other; covered with a thin brown membranous outer coat, and an inner reddish-yellow one; internally white and solid, and when cut yielding a whitish, turbid juice of a disagreeable odor and bitter taste. Dried slices two or three millimetres thick, yellowish at their circumference, somewhat reniform in outline; firm, whitish, amylaceous; breaking readily with a short fracture. No odor; taste bitter." *Br.*

The cut surface is white, and of an amylaceous aspect. Examined with the microscope, the corm is seen to be composed of large irregular cells, full of ovoid, angular, sometimes compound, starch grains, and interspersed with spiral vessels in vascular bundles. The odor of the recent corm is said to be hircine. It is diminished, but not lost, by drying. The taste is bitter, hot, and acrid.

A. T. Thompson stated that the milky juice of fresh colchicum produces a fine blue color if rubbed with the tincture of guaiac, and that the same effect is obtained from an acetic solution of the dried corm. He considered the appearance of this color, when the slices were rubbed with a little distilled vinegar and tincture of guaiac, a proof that the drug was good and had been well dried. J. M. Maclagan has shown that the value of the test consists simply in proving that the drying has not been effected at a heat above 82.3° C; the color being due to the action of an oxydase. A very deep or large notch in the circumference of the slices is an unfavorable sign, as it indicates that the corm has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with lead acetate and subacetate, mercurous nitrate, and silver nitrate, and a slight precipitate with tannic acid.

Colchici Semen.—The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil or in confined gardens. (Williams.)

Description and Physical Properties.—"*Unground Colchicum Seed.*—Ovoid or irregularly globular, minutely pointed at the hilum, and with a distinct beak or caruncle approximately opposite to the hilum; from 2 to 3 mm. in diameter and, when fresh, with a tendency to cohere in small clumps; externally dark brown, finely pitted; tough and of bony hardness; internally whitish or light brown; nearly inodorous; taste bitter and acrid.

"*Structure.*—Seed coat of a few layers of more or less collapsed cells with thin, reddish-brown walls; the endosperm parenchyma, with thick porous walls, containing fixed oil and aleurone grains, the latter from 0.003 to 0.015 mm. in diameter; the embryo small; the beaked portion or caruncle containing thin-walled parenchyma with ovoid, ellipsoidal or polygonal starch grains from 0.005 to 0.020 mm. in diameter." *U. S.*

"About two and a half millimetres in diameter, subglobular, slightly pointed at the hilum, rough and of a dull reddish-brown color, minutely pitted, very hard and tough. Endosperm oily; its cells with thickened walls and large pits. No odor; taste bitter and acrid." *Br.*

They are chiefly composed of a gray horny endosperm constituted of very thick-walled cells, and surrounded by a closely adherent testa. The leafless embryo is very small, and is situated close to the surface opposite the strophiole. It has been found that the percentage of alkaloids in colchicum seeds is in inverse proportion to the specific weight of the seeds. There is present nearly 20 per cent. of a semi-drying oil of pungent taste and from 2 to 5 per cent. of reducing sugars. The seeds and powder are very seldom adulterated. Judd, however, reports examining a powder which contained fully 50 per cent. of powdered fœnugreek seed. (*Bull. A. Ph. A.*, 1909, p. 193.)

The therapeutic value of both colchicum seed and corm probably depend on their alkaloid (see *Colchicina*).

The U. S. Pharmacopœia directs that colchicum seed should contain not less than 0.45 per cent. of colchicine, and the corm not less than 0.35 per cent., to be determined by the following process:

Assay.—"Place 15 Gm. of Colchicum Seed, in fine powder, in a 500 cc. flask and add 290 cc. of distilled water and 10 cc. of solution of lead subacetate. Weigh the flask and contents, and digest the mixture at from 60° to 70° C. for three hours with occasional agitation. Cool, add distilled water to restore the original weight, and filter off 200 cc. Add 2 Gm. of sodium phosphate to the clear filtrate, or sufficient to completely precipitate the lead, shake the mixture frequently during half an hour, and filter off 100 cc., representing 5 Gm. of Colchicum Seed. Shake out the alkaloid from the filtrate with chloroform until completely extracted, as shown by testing with iodine T.S., and evaporate the chloroform solution. Add about 1 cc. of alcohol, and again evaporate. Repeat this operation once more, and dry the residue to constant weight at 100° C. To this weighed residue contained in a flask add 5 cc. of tenth-normal sulphuric acid and 5 cc. of distilled water, adding a few drops of chloroform, and heat the mixture for ten minutes at 70° C. Filter the liquid through a pledget of purified cotton, wash the flask and cotton with distilled water, reject the filtrate and washings, and remove as much of the water from the cotton as possible. Dissolve any insoluble residue that may remain on the cotton by washing it first with a little alcohol and then with ether; collect the alcohol-ether washings in the flask, evaporate, and dry the residue to constant weight at 100° C. Deduct this weight from the weight of residue previously obtained. The difference will be the weight of colchicine obtained from 5 Gm. of Colchicum Seed (Proximate Assays)." *U. S.*

For other methods of assay see Schwickerath (*Ph. Rund.*, 1893, 282) and Bredemann (*Ap. Ztg.*, 1903, xviii).

Uses.—The investigations into the physiological action of colchicum have not as yet yielded a very clear explanation of its therapeutic effects. Dixon and Malden (*J. P.*, 1908, xxxviii, p. 50) have found that it is an active stimulant to the unstriped muscle, increasing intestinal and uterine contractions and bronchial tonus. After large doses it depresses the vasomotor system, causing a marked fall in the blood pressure. When injected subcutaneously in somewhat smaller doses it producse a transient decrease in the number of leukocytes followed after twenty-four hours by an enormous increase, the alterations being especially notable in the number of polymorphonuclear corpuscles. These effects appear to be the result of an action upon the bone marrow. Jackson and Blackfan (*J. A. M. A.*, 1906, xlvii) find an increased output of uric acid under its influence, but they believe this is due rather to an increased formation than a more active elimination, but Denis (*J. P. Ex. T.*, 1915, vii, 609) was unable to detect any change in the amount of uric acid either in the urine or blood.

The poisonous properties of colchicum were known to the ancients, but, while it is generally supposed that the hermodactyls were derived from some species of the genus, the use of meadow-saffron cannot be certainly traced back further than the sixteenth century. Although it has from time to time been recommended for various complaints, it is used to-day only in the treatment of *gout*. There is considerable clinical evidence that full doses of colchicum administered during the acute attack of a *podagra* will often abort it. The treatment, however, is not without serious danger and most clinicians urge caution in the use of colchicum during the attack. It appears also to be of service in those more chronic conditions of disturbed metabolism known variously as uric acid diathesis or *lithemia*.

In preparing colchicum pharmaceutically, if it be desired to retain the colchicine unchanged, both acids and alkalies should be avoided and as far as possible also heat. As pointed out below, under various conditions colchicine may be decomposed into colchiceine, colchicinic acid, and various allied products. Whether these derivatives of colchicine possess the therapeutic virtues of the natural alkaloid is uncertain, but Fuehner (*A. E. P. P.*, 1913, lxxii, p. 228) has shown that colchiceine is very much less toxic than colchicine.

When taken internally in therapeutic dose, colchicum usually produces no other symptoms than intestinal pains and looseness of the bowels. In some rare cases it is said to give rise to copious diuresis or diaphoresis instead of purging. When larger amounts are exhibited, the purging is more pronounced, and there may be also vomiting. With these symptoms there may be some depression, which seems to be due to the gastro-intestinal irritation rather than to the direct action of the poison. In an overdose, it may produce dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, great thirst, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, such as headache, delirium, and stupor, are among the results of its poisonous action. A peculiarity of its influence is that when its dose is increased beyond a certain point there is not a corresponding increase in the rapidity of the fatal issue. This is probably because it kills not by a direct influence upon the heart or the nervous system, but by causing gastro-enteritis. On post-mortem examination the alimentary mucous membrane is found much inflamed.

Dose, of the dried corm and seed, from two to eight grains (0.13–0.52 Gm.), which may be repeated every four or six hours until its effects are obtained.

COLCHICINA. U. S.

COLCHICINE

"An alkaloid [$C_{22}H_{25}O_6N$] obtained from colchicum." *U. S.*

Colchicine, *Fr.;* Colchicin, *G.*

Colchicine is found in various species of *Colchicum* and in *Gloriosa superba* (see Part II) and in species of *Merendera* (Clewer, Green and Tutin, *Tr. Chem. Soc.*, 1915, cvii, p. 835).

When hydrolized, as by boiling with diluted acids, colchicine is first split into methanol and *colchiceine* (acetyltrimethyl-colchicinic acid). By the further action of hydrochloric acid the latter is decomposed eventually into *colchicinic acid* (Windaus, *Sitzungsber. Heidelb. Akad. Wiss.*, 1910, 1911, and 1914; also *Chem. Soc. Abstr.*, 1924, i, 72). Colchiceine, according to Oberlin (*M. Chem.*, 1888, ix, 870), occurs naturally, along with colchicine, in the autumn corms and seeds, but according to Zeisel was probably formed by decomposition during extraction.

Colchicine has also been built up synthetically from colchiceine, sodium methylate, and methyl iodide, which are heated together to 100° C. (Johanny, *M. Chem.*, ix, 868.) It forms precipitates with the usual alkaloidal reagents. Its solutions are strongly lævo-rotary.

Description and Physical Properties.—"Pale yellow, amorphous scales, or powder, turning darker on exposure to light. It is odorless, or nearly so. *Caution—Colchicine is extremely poisonous.* One Gm. of Colchicine is soluble in 22 cc. of water, 220 cc. of ether, and in 100 cc. of benzene, at 25° C. It is freely soluble in alcohol and in chloroform, and is insoluble in petroleum benzin.

"Colchicine melts between 142° and 146° C. Its aqueous solution (1 in 30) is neutral to litmus paper, and is lævorotatory. An aqueous solution of Colchicine (1 in 30) is yellow, its color becoming intensified by the addition of inorganic acids. Mix about 0.001 Gm. of Colchicine with a few drops of sulphuric acid: a lemon-yellow color is produced, which, on the addition of a drop of nitric acid, changes to greenish-blue, rapidly becoming reddish and finally yellow, or almost colorless. On adding an excess of sodium hydroxide T.S., the color is changed to red.

"The addition of 2 drops of ferric chloride T.S. to 5 cc. of an aqueous solution of Colchicine (1 in 100) produces no color (*colchiceine*), but on heating, a brownish-red color is developed, which changes to brownish-black. One drop of ferric chloride T.S. added to 1 cc. of an alcoholic solution of Colchicine (1 in 20) at once produces a garnet-red color. The ash from 0.1 Gm. is negligible. Heat a mixture of about 0.01 Gm. of Colchicine, 2 cc. of sodium hydroxide T.S., and one drop of aniline: no odor of phenylisocyanide is developed (*chloroform*).

"Preserve in well-closed containers, protected from light." *U. S.*

Vanderkleed and E'we (*Proc. P. Ph. A.*, 1916, p. 279) point out that some commercial samples of colchicine contain chloroform in comparatively stable form, which might be called chloroform of crystallization. This not only interferes with the melting point determination, but inasmuch as the amount of chloroform present is sometimes over 20 per cent. it becomes a fraud as well.

Uses.—The alkaloid colchicine acts like colchicum, according to Maret and Combemale, in doses of one-twelfth of a grain (0.005 Gm.) producing violent diarrhea, with diminished urinary secretion; in doses of one thirty-second of a grain (0.002 Gm.) causing some abdominal disturbance, with increased diuresis. According to J. Sprega, three grains (0.2 Gm.), repeated in three hours, caused violent gastro-enteritis, ending in death in thirty-one hours. (*Gazz. d. Ospitali,* Oct., 1890.) *Colchicine salicylate* is a yellow amorphous powder, soluble in water, alcohol, and ether, the dose being one-hundredth of a grain (0.0006 Gm.) every four hours.

Dose, one one-hundred-and-fiftieth to one one-hundredth of a grain (0.0004–0.0006 Gm.).

COLLODIUM. U. S. Br.

COLLODION Collod.

Collodion, *Fr. Cod.;* Collodium, *P. G.;* **Kollodium**, *G.;* Collodio, *It.;* Colodion, *Sp.*

"Pyroxylin, 40 Gm.; Ether, 750 cc.; Alcohol, 250 cc.; to make about 1000 cc. Add the alcohol to the pyroxylin contained in a suitable bottle, shake the mixture thoroughly, add the ether, and again shake the mixture until the pyroxylin is dissolved. Cork the bottle well, and set it aside until the liquid becomes clear. Finally decant the clear portion from any sediment which may have deposited, and transfer it to containers which must be well closed." *U. S.*

"Pyroxylin, 21 grammes; Ether, 750 millilitres; Alcohol (90 per cent.), 250 millilitres. Immerse the Pyroxylin in the Alcohol; add the Ether, shake occasionally until dissolved; set aside for a few days; decant if necessary." *Br.*

Collodion is a solution of pyroxylin in alcohol and ether. Formerly the U. S. Pharmacopœia directed that the gun cotton be prepared at the time of making the collodion, giving directions for the purpose, but at the revision of 1870 the process of the British Pharmacopœia was substantially adopted, a formula for the preparation of pyroxylin being given separately in the Pharmacopœia. A process for the preparation of pyroxylin is not official in the U. S. Pharmacopœia, but the British Pharmacopœia still retains a process. (See *Pyroxylinum.*)

Acetone has been used as a solvent for pyroxylin, and collodion so prepared is on the market.

Description and Physical Properties.—"A clear, or slightly opalescent, syrupy liquid. It is colorless, or slightly yellowish and has the odor of ether. *It is highly inflammable.* Specific gravity: 0.765 to 0.775 at 25° C. When exposed to the air in a thin layer, it leaves a transparent, tenacious film. When mixed with an equal volume of distilled water, a viscid, stringy mass of pyroxylin separates. The aqueous liquid is not acid to litmus paper.

"**Assay.**—Pour quickly about 10 cc. of Collodion into a tared flask, stopper, and weigh accurately, then warm it on a water bath, and add 10 cc. of distilled water, drop by drop, with constant stirring. Evaporate the mixture on a water bath, and dry the residue to constant weight at 110° C. The pyroxylin so obtained corresponds to not less than 5.1 per cent. of the Collodion taken, corresponding to about 4 Gm. of pyroxylin in 100 cc. of Collodion at 25° C. The pyroxylin obtained burns rapidly, with a yellow flame.

"Preserve in well-closed containers, in a cool place, remote from fire." *U. S.*

"A colorless, highly inflammable liquid of syrupy consistence and ethereal odor. Dries quickly upon exposure to the air, and leaves a thin transparent film, which contracts rapidly on drying and is insoluble in *water* or *alcohol* (90 per cent.)." *Br.*

When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stoppered. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals. The addition of a mixture of 3 volumes of ether and 1 volume of alcohol will generally restore the collodion to its original condition.

Uses.—Collodion was first applied to the purposes of surgery by J. Parker Maynard, of Boston, when a student of medicine, in January, 1847, although, as pointed out by Kahlbaum, Schoenbein, the discoverer of gun-cotton, suggested the surgical use of an ethereal solution in 1846. (*Nat. Drug.,* 1902, 8.) It is employed for holding together the edges of incised *wounds,* for covering *ulcers,* abraded or diseased surfaces, *chilblains, chapped nipples,* etc., with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It should be remembered that while it protects the underlying tissues from external contamination, it also prevents the escape of any toxic materials already present; to hermetically close an infected wound, as with collodion, is an invitation to blood-poisoning. It is applied brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material, which is soluble neither in water nor in alcohol. The rigid film thus formed contracts with a good deal of force. This property adapts collodion for certain purposes, such as drawing together the edges of wounds, exciting pressure on buboes, etc. When, however, the surgeon desires simply to protect a surface, a flexible, non-contracting film is preferable, and the official flexible collodion should be used. Collodion has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodion* has been proposed by C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on *tumors.* See *Collodion Iodi,* N. F., Part III. Aran has proposed a *ferruginous collodion,* made of equal parts of collodion and tincture of ferric chloride, as a remedy in *erysipelas.* A *caustic collodion* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodion. Macke, of Sorau, has used this preparation for destroying *nævi materni.* The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (For formulas in which collodion is made the vehicle of croton oil, iodoform, salicylic acid, tannin, etc., see National Formulary, Part III.) All these medicated collodions are best applied by means of a camel's-hair brush.

COLLODIUM FLEXILE. U. S., Br.

FLEXIBLE COLLODION Collod. Flex.

Collodion élastique, *Fr.;* Collodium elasticum, *P. G.;* Elastiches Collodium, Kollodium, *G.;* Collodio elastico, *It.;* Colodion elastico, *Sp.*

"Camphor, 20 Gm.; Castor Oil, 30 Gm.; Collodion, a sufficient quantity to make 1000 Gm. Weigh the ingredients, successively, into a dry, tared bottle, stopper, and shake the mixture until the camphor is dissolved. Keep the product in well-closed containers, in a cool place, remote from fire." *U. S.*

"Collodion, 940 *millilitres;* Canada Turpentine, 40 *grammes;* Castor Oil, 20 *grammes.* Mix." *Br.*

The contractility of the collodion film has long been felt as a drawback to its use simply for the purposes of protection. C. S. Rand proposed to obviate this by dissolving one part of gun cotton and three of Venice turpentine in twenty parts of ether. To give more flexibility to the film, Sourisseau, of Kaiserberg, suggested the addition of one part of elemi to twelve of collodion. According to Startin, of London, opacity and elasticity may be imparted at the same time by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity may also be given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of Guersant, who found it useful, thus modified, in *erysipelas;* and the proportion of castor oil may be increased if thought desirable. This is the method preferred by the French Codex. According to Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the color of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Meller has proposed a solution of shellac in highly rectified alcohol, so as to have a gelatinous consistence, as a substitute for collodion. Of all these plans, probably that followed in the official direction is the best.

Off. Prep.—Collodium Bitumini Sulphonati, *N. F.;* Collodium Salicylici Compositum, *N. F.;* Collodium Stypticum, *N. F.;* Collodium Tiglii, *N. F.*

COLLODIUM VESICANS. Br.

BLISTERING COLLODION Collod. Canth.

Collodium Cantharidatum, *U. S. IX;* Cantharidal Collodion; Vesicating Collodion; Collodium Cantharidale, Collodion vésicant (cantharidé), *Fr.;* Collodium Cantharidatum, *P. G.;* Spanischfliegen-Kollodium, Blasenziehendes Collodium, *G.*

"Pyroxylin, 25 *grammes;* Cochineal, in powder, 10 *grammes;* Blistering Liquid sufficient to produce 1000 *millilitres.* Shake together until the Pyroxylin is dissolved, set aside till clear, and decant the clear liquid." *Br.*

The U. S. IX recognized an analogous preparation, but made directly from cantharides. The formula for this was:

"Cantharides, in fine powder, *sixty grammes;* Glacial Acetic Acid, *five mils;* Flexible Collodion, *eighty-five grammes;* Acetone, *a sufficient quantity,* to make *one hundred grammes.* Mix the cantharides with *fifty-five mils* of acetone, to which the glacial acetic acid has been added, and set the mixture aside in a closely covered container for twenty-four hours. Then transfer it to a percolator and continue the percolation with acetone until the drug is practically exhausted. Reduce the percolate by distillation on a water bath, in a tared flask, to *fifteen grammes* and, when cold, dissolve this concentrated extract in *eighty-five grammes* of flexible collodion. Finally allow the solution to stand for several hours, and decant the clear liquid from any sediment which may have deposited, and transfer the product to containers, which must be well-closed. Keep Cantharidal Collodion in a cool place, remote from fire." *U. S. IX.*

Cantharidal collodion is a convenient but uncertain epispastic. It may be applied to the surface by means of a camel's-hair brush, and after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

COLOCYNTHIS. U. S. (Br.)

COLOCYNTH Colocyn.
[Colocynth Pulp, Bitter Apple]

"Colocynth is the dried pulp of the unripe but fully-grown fruit of *Citrullus Colocynthis* (Linné) Schrader (Fam. *Cucurbitaceæ*). Colocynth contains not more than 5 per cent. of seed and not more than 2 per cent. of epicarp, and yields not more than 2 per cent. of extractive with purified petroleum benzin, and not more than 6 per cent. of acid-insoluble ash." *U. S.*

"Colocynth Pulp is the dried pulp of the fruit of Citrullus Colocynthis, *Schrad.*, freed from seeds." *Br.*

Colocynthidis Pulpa, *Br.;* Colocynth Pulp, Bitter Gourd, Apple, or Cucumber; Fructus Colocynthidis; Poma Colocynthidis; Coloquinte, *Fr. Cod.;* Pulpe de Coloquinte, *Fr.;* Fructus Colocynthidis, *P. G.;* Coloquintenapfel, Koloquintenmark, Koloquinten, *G.;* Coloquintide, *It.;* Coloquintida, *Sp.*

Although the U. S. Pharmacopœia has followed the British authority and defined Colocynth as the dried pulp, since it is not commercially possible to exclude the seeds entirely, a few being imbedded in the pulp itself, the U. S. P. wisely allows a maximum of 5 per cent. of seeds. It is estimated that every 100 pounds of colocynth fruit will yield 30 pounds of pulp and about 70 pounds of seeds. Tunmann (*Suedd. Apoth. Zeit.*, 1907, p. 503) states that the seeds do not contain medicinally active constituents. Francis (*Proc. A. Ph. A.*, 1906, p. 336), on the other hand, says that if the seeds are first deprived of their fixed oil with benzin, dried and then extracted with 75 per cent. alcohol, the extract is almost as active as the U. S. P. product.

Citrullus Colocynthis, or *bitter cucumber,* is an annual plant, bearing considerable resemblance to the common watermelon. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighboring bodies, to which they attach themselves by their numerous tendrils. The leaves, which stand alternately on long petioles, are triangular, many-cleft or parted variously sinuated; obtuse, hairy, of a fine green color on the upper surface, rough and pale on the under. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular berry, of the size of a small orange, yellow and smooth when ripe, and contains, within a hard, coriaceous rind, a white, spongy pulp, enclosing numerous ovate, compressed, white or brownish seeds.

The plant is a native of Asia and Africa. Burckhardt, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope, and Ainslie says that it grows in many parts of Lower India, particularly in sandy places near the sea. It is said to be cultivated in Spain, the island of Cypress, Morocco and in the neighboring countries, and even to have been collected in Japan. Colocynth is imported in wooden cases; the bulk of the present supplies to the United States is collected in the Soudan and shipped from Cairo. That from the maritime plain between the mountains of Palestine and the Mediterranean is chiefly shipped from Jaffa, and is known as *Turkish colocynth.* It is said to be of superior quality. The fruit is gathered in autumn, when it begins to become yellow, and, having been peeled, is dried quickly in a stove or in the sunshine. Thus prepared, it is imported from the Levant. Small quantities are said to be imported into England from Mogador in the form of brown, unpeeled globular gourds. The so-called *Persian colocynth* is very small, and has apparently been compressed in a fresh state, so that the position of the seeds is perceptible through the dry pulp. The microscopic structure and the proportion of the pulp to the seed appear to be the same as in other colocynths. Colocynth has been grown in New Mexico, but, according to Sayre, the American colocynth is less active.

As found in commerce, colocynth is in whitish, globular berries, from 6 to 7 cm. in diameter, very light and spongy, and abounding in seeds which constitute three-fourths of the fruit.

Description and Physical Properties.—"*Unground Colocynth.*—In light, spongy, easily-broken pieces; yellowish-white or light brown with occasional small patches of darker epicarp; odor slight; taste intensely bitter. Fruits, before removal of seed, nearly globular, from 4 to 10 cm. in diameter, with three large lenticular cavities between the three carpels, hence easily separable longitudinally into three parts. Seeds ovoid compressed, light yellow to brown.

"*Structure.*—Large, thin-walled pitted parenchyma tissue traversed by bicollateral vascular bundles having spiral tracheæ and accompanied by occasional irregular tubular laticiferous vessels.

"*Powdered Colocynth.*—Yellowish-white or buff and characteristically flaky; consisting chiefly of fragments of the parenchyma and vascular bundles. Presence of epicarp and seed indicated by characteristic stone cells, and of the seed, by aleurone grains, and globules of fixed oil.

"**Assay.**—Proceed as directed under non-volatile ether-soluble extractive, using purified petroleum benzin as the solvent." *U. S.*

"White, spongy, light fragments. The powdered Pulp exhibits abundant débris of large, thin-walled parenchymatous cells but no starch, and not more than an occasional sclerenchymatous cell or group of such cells. No odor; taste intensely bitter. Yields not more than 2 per cent. of fixed oil to *petroleum spirit.* Ash not less than 9 per cent." *Br.*

Barclay considers the estimation of ash in powdered colocynth useful in proving its freedom from seeds. The pulp yields from 8.6 to 14 per cent. of ash, the seeds from 2 to 4 per cent., the whole apple 4.6 per cent. (*Am. Drug.*, 1896, 152.) Water and alcohol extract the virtues of colocynth. It is a matter of importance to be able to determine whether the drug miller who usually powders colocynth is careful to reject the seeds. If the seeds have been ground with the dried pulp, the microscope will show the presence of numerous albuminous granules derived from the cotyledons. These are best found by putting a small amount of the powder on the glass slide, adding a drop of water, and gently rubbing the cover glass over it; fragments of the double-walled embryo sac show on the outer side elongated, more or less hexagonal, thin-walled cells, and on the inner side irregular, tabular, thick-walled cells. If powdered colocynth contains a large number of starch granules it has probably been adulterated.

Constituents.—Power and Moore (*Tr. Chem. Soc.,* 1910, xcvii, p. 99) found in colocynth an alkaloidal principle which has a violent purgative effect, but this is not the only active principle of the crude drug, because both ether and chloroform extracts of the resin, when free from the alkaloidal principle, were still purgative. They find also alpha-elaterin, but none of the active beta-elaterin. (See *Elaterinum.*) The bitter principle of colocynth obtained by Vauquelin and by him called *colocynthin* (also known as *citrullin* by Ahrends), according to Power and Moore, is a mixture of the alkaloid and a crystallizable alcohol, *citrullol.* Waltz supposed that he had found another peculiar principle, *colocynthitin.* It was obtained by treating with ether the alcoholic extract previously exhausted by water, decolorizing the ethereal solution with animal charcoal, evaporating to dryness, and dissolving the residue in anhydrous alcohol, which deposited it in crystals on spontaneous evaporation. It is white and tasteless, and is probably a resin. (*N. Jahrbuch der Pharm.,* xvi, 10.)

An infusion of colocynth, made with boiling water, gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and then with water, 168 parts of alcoholic and 216 of aqueous extract. (See also paper by George Wagner, *Proc. A. Ph. A.,* 1893, 179.)

Uses.—The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (Christison.) Even in moderate doses it sometimes acts with much harshness, and it is therefore seldom prescribed alone. By some writers it is said to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used in obstinate *dropsy,* and in various affections depending on disordered action of the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy, and in this form is extensively employed. It is best administered in minute division, effected by trituration with gum or farinaceous matter.

Thunberg states that the fruit of *C. Colocynthis,* at the Cape of Good Hope, is rendered so mild by being properly pickled that it is eaten both by the natives and by the colonists; but, as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

Dose, one to five grains (0.065–0.32 Gm.).

CONDURANGO. N. F.

CONDURANGO

"Condurango is the dried bark of *Marsdenia Cundurango* (Triana) Nichols (Fam. *Asclepiadaceæ*). Condurango contains not more than 2 per cent. of wood or other foreign organic matter." *N. F.*

Condurango Cortex; Cortex Condurango, *P. G.*

According to an official investigation made in 1873 by Passed Assistant Surgeon Joseph G. Ayers, U. S. N., there are at least ten different plants known in the republic of Colombia as *condurango.* The variety which has been used in *cancer,* and which may be considered as genuine condurango, is the *condurango blanco,* the product of a climbing asclepiadaceous vine from ten to thirty feet in length and from one to two inches in diameter. The plant is the *Marsdenia Condurango* of G. H. Reichenbach. (*Gonolobus Condurango,* Triana.) It is indigenous to Ecuador but also grows in other parts of South America. The bark is prepared by pounding the stem with a mallet to separate it, and then drying it in the sun.

Under the name of *Guayaquil condurango* a drug has appeared in the European markets composed of pieces of bark and fragments of woody branches, believed to be derived from an asclepiadaceous plant closely related to the genus *Gonolobus. Mexican condurango* is composed of split stems or thin adherent bark, and is thought to be yielded by an Aristolochia. For full description, see *Ph. Rund.,* May, 1888.

Description and Physical Properties.—"*Unground Condurango.*—In quills or transversely curved pieces, usually from 4 to 13.5 cm. long; bark 1 to 6 mm. thick; outer surface light grayish brown to dark brown, nearly smooth and with numerous lenticels, or more or less scaly and considerably roughened, occasionally with whitish lichens bearing brownish black apothecia; inner surface grayish white or light brown, longitudinally striate; fracture short-fibrous in the outer portion and granular in the inner portion. Odor slightly aromatic, especially marked in the fresh drug; taste bitter and aromatic.

"*Structure.*—Corky layer consisting of several rows of thin-walled cells, walls occasionally lignified and frequently with yellowish brown contents; a layer of phelloderm of eight to ten rows of cells, containing starch grains and crystals of calcium oxalate; a layer of collenchyma more or less interrupted by parenchyma, and containing chloroplastids, starch grains, and rosettes of calcium oxalate; a layer of parenchyma, with groups of bast fibers and laticiferous vessels in an interrupted circle; inner bark with large groups of stone cells, medullary rays one or two cells in width, numerous laticiferous cells accompanied by small groups of sieve cells, parenchyma containing either starch grains or rosettes of calcium oxalate, and an occasional isolated bast fiber or small group of stone cells.

"*Powdered Condurango.*—Light yellowish brown, consisting chiefly of groups of stone cells and parenchyma the latter containing calcium oxalate crystals and starch grains; calcium oxalate chiefly in rosettes from 0.015 to 0.040 mm. in diameter, occasionally in single prisms, 0.010 to 0.035 mm. in length; starch grains simple or 2- to 4-compound, the individual grains being from 0.003 to 0.020 mm. in diameter; stone cells up to 0.190 mm. in length, chiefly in large groups, the individual cells being more or less irregular in shape and with very thick porous yellow walls, the lumina being usually filled with air; bast fibers non-lignified very long and from 0.010 to 0.035 mm. wide; fragments of thin-walled latex tubes from 0.015 to 0.030 mm. in diameter and filled with a granular substance; fragments of cork grayish or light yellowish brown.

"Macerate 1 Gm. of powdered Condurango in 5 cc. of cold water; filter and heat the filtrate in a test tube; it becomes cloudy, but on cooling assumes its original transparency." *N. F.*

Vulpius (*P. J.*, 1885, 1066) found in it *condurangin*, a glucoside, very closely allied to *vincetoxin* of Tanret, but it was probably a mixture of various glucosides. Carrara (*A. J. P.*, 1892) obtained from the so-called condurangin of commerce two principles: One insoluble in water, soluble in benzene, a light, almost white, powder, melting at from 60°–61° C., and of the composition $C_{20}H_{32}O_6$. Both compounds are decomposed by acids, yielding a brown pitchy substance, insoluble in water. Merck gives the following constituents of condurango: *Alpha-condurangin*, $C_{20}H_{32}O_6$; *Beta-condurangin*, $C_{18}H_{28}O_7$; *Conduransterin*, $C_{30}H_{50}O_2$, and also a trace of an alkaloid resembling strychnine in action. Boehm (*M. M. W.*, lv, p. 1775) regards condurangin as a derivative of cinnamic acid. According to Firbas, condurangin, in solution, can be recognized by freeing from alcohol with gentle warmth, precipitating with a saturated solution of sodium chloride, dissolving the precipitate in chloroform, and adding a liquid composed of equal parts of sulphuric and hydrochloric acids and alcohol. On warming, the mixture assumes a green color, which turns a beautiful greenish-blue on the addition of a trace of ferric chloride. This *Lafon reaction* is given also by adonidin, oleandrin, sapotoxin and digitoxin.

Uses.—Brunton reached the conclusion that *Condurango blanco* was inert, but Kobert found condurangin to be a violent poison, causing convulsions followed by paralysis; he believes it to be a mixture of several principles. (*S. Jb.*, 1889, No. 9.) H. Chiriboga states that three drachms of the bark taken by himself in the form of decoction produced considerable activity of the circulation, copious diaphoresis, increased secretion of urine, and even some vertigo and disturbance of vision. Condurango was at one time reputed to possess value in the treatment of *cancers* and was also used in South America in *syphilis* but there is no satisfactory evidence of its usefulness in either condition.

Prof. P. E. Hommell recommends *Mistura condurango et ulmi* and *Fluidglycerate of condurango* for the internal administration of the drug. (See *Proc. N. Jersey Pharm. Assoc.*, 1913, 80; also *M. R.*, 1913, 231.)

Dose, sixty grains (4 Gm.).

Off. Prep.—Fluidextractum Condurango, *N. F.*

CONFECTIO PIPERIS. Br.

Electuarium Piperis; Electuaire de Poivre, *Fr.*; Pfefferlatwerge, *G.*

"Black pepper of commerce, in powder, 100 *grammes;* Caraway Fruit, in powder, 150 *grammes;* Purified Honey, 750 *grammes.* Mix." *Br.*

This preparation was intended as a substitute for *Ward's Paste*, which acquired some reputation in Great Britain as a remedy in *piles* and ulcers of the rectum. To be of service, it must be continued, according to Brodie, for two, three, or four months. Its stimulating properties render it inapplicable to cases attended with much inflammation.

Dose, from one to two drachms (3.9–7.7 Gm.), repeated two or three times a day.

CONFECTIO ROSÆ GALLICÆ. Br.

CONFECTION OF ROSES

Conserva Rosarum; Conserve de Rose rouge, *Fr.*; Rosen-Conserve, *G.*; Conserva de Rosso, *Sp.*

Confection of Rose is not recognized by the U. S. but is official in the N. F. (See Part III.)

"Fresh Red-Rose Petals, 250 *grammes;* Refined Sugar, 750 *grammes.* Beat together in a stone mortar." *Br.*

The formula given in the N. F. for confection of rose differs in several particulars, from the Br. Dried roses have been substituted for the fresh as the latter are not brought to our market. A part of the sugar has been replaced by honey and added odor given by the use of stronger rose water.

Confection of Rose is slightly astringent; it is used almost exclusively as a vehicle, and is admirably adapted as an excipient and to impart consistence to the pilular mass.

Off. Prep.—Pilula Hydrargyri, *Br.*

CONFECTIO SENNÆ. Br.

CONFECTION OF SENNA

Electuarium Sennæ Compositum, Electuarium Lenitivum; Electuaire de Séné composé, Electuaire lenitif, *Fr.;* Electuarium e Senna, *P. G.;* Sennalatwerge, *G.;* Elettuario lenitivo, *It.*

Confection of Senna is not official in the U. S., but the National Formulary recognizes a similar preparation. (See Part III.)

"Senna Leaves, in powder, 100 *grammes;* Coriander Fruit, in powder, 40 *grammes;* Figs of commerce, 160 *grammes;* Tamarinds, 120 *grammes;* Cassia Pulp, 120 *grammes;* Prunes of commerce, 80 *grammes;* Extract of Liquorice, 15 *grammes;* Refined Sugar, 400 *grammes;* Distilled Water sufficient to produce 1000 *grammes.* Boil the figs and prunes gently with three hundred and fifty grammes of Distilled Water in a covered vessel for four hours; add more Distilled Water to make up the quantity to its original weight, and then incorporate the Tamarinds and Cassia Pulp; digest for two hours; rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts; to the pulp thus obtained add the Refined Sugar and Extract of Liquorice, dissolving them by the aid of gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders; mix the whole thoroughly; make the weight of the resulting Confection one thousand grammes, either by evaporation or by the addition of more Distilled Water." *Br.*

The preparation of the N. F. differs from the Br. in that it omits the extract of licorice, using a larger amount of sugar and substituting the oil of coriander for the seed. The latter is an improvement because it is almost impossible to powder coriander fine enough to avoid hard particles except by drying it to such an extent as to deprive it of its volatile oil. The oil of coriander should be dropped upon a portion of the powdered senna contained in a mortar or suitable vessel and this lightly triturated with the rest of the powdered senna so as to distribute it uniformly and the mixture should then be added to the pulpy mass.

A very good, pleasant laxative, admirably adapted to cases of habitual costiveness, especially in pregnant women, and in persons affected with *piles.*

Dose, one to two drachms (3.9–7.7 Gm.), at bedtime.

CONFECTIO SULPHURIS. Br.

CONFECTION OF SULPHUR

Electuarium Sulphuris; Electuaire de Soufre, *Fr.;* Schwefelatwerge, *G.*

"Precipitated Sulphur, 450 *grammes;* Acid Potassium Tartrate, in powder, 110 *grammes;* Tragacanth, in powder, 5 *grammes;* Syrup, 210 *millilitres;* Tincture of Orange, 55 *millilitres;* Glycerin, 170 *millilitres.* Mix." *Br.*

This is merely a mode of administering the two laxatives, sulphur and potassium bitartrate, and the relative proportion of the latter is so small that it can have little effect. The addition of tragacanth is due to a suggestion of Peter Boa, who found that without it a syrupy layer of liquid formed on top of the confection. (*P. J.,* 1882, 682.) The syrup of orange peel, formerly directed, has been replaced in the last two editions by syrup and tincture of orange, evidently because the syrup of orange peel did not keep well, while the glycerin serves to retain the proper consistence of the confection.

Dose, one to two drachms (3.9–7.7 Gm.) or more.

CONFECTIONES

CONFECTIONS

Electuaries; Conserves, Electuaries, Saccharolés mous, *Fr.;* Konserven, Latwergen, *G.;* Elettuario, *It.;* Electuario, *Sp.*

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. But two confections, Rose and Senna, were retained in the Eighth Revision of the U. S. Pharmacopœia and in the Ninth Revision both were dropped but admitted to the National Formulary. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division before proceeding to the consideration of the individual preparations.

Conserves consist of undried vegetable substances and refined sugar beaten into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now used are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be in fine powder.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for official direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Other information on conserves, electuaries and confections with formulas for those which were formerly official, will be found in previous editions of the *U. S. D.*

CONIUM. N. F.

CONIUM [Poison Hemlock]

"Conium consists of the dried full grown, but unripe fruit of *Conium maculatum* Linné (Fam. *Umbelliferæ*). Conium contains not more than 2 per cent. of foreign fruits, seeds, or other foreign organic matter and yields not less than 0.5 per cent. of coniine. After being kept for more than two years, it is unfit for use. Conium should be carefully dried and preserved." *N. F.*

Conii Fructus, *Br.*, 1898.; Hemlock, Spotted Hemlock or Parsley, Fool's Parsley, St. Bennett's Herb; Spotted Cowbane; Herba Cicutæ (Majoris); Fructus Conii; Ciguë officinale, Grande Ciguë, *Fr. Cod.*; Schierling, Gefleckter Schierling, *G.*; Cicuta maggiore, *It.*; Cicuta (Fruto), *Sp.*

Conium maculatum is an umbelliferous plant, native of Europe, but naturalized in the United States. It is sometimes referred to as *cicuta* but this name properly belongs to another genus of *Umbelliferæ* (see *Cicuta*). The conium usually grows in clusters along road-sides or on waste grounds and is found most abundantly near old settlements. It reaches a height of from 2 to 5 feet and is characterized by large, pinnately decompound leaves—the lower being sometimes more than a foot in length, the upper leaves being sessile and the lower petioled—a spotted stem and umbels bearing white flowers in June and July. The whole plant, during midsummer, exhales a fetid odor, compared by some to that of mice, by others to that of the urine of cats, and narcotic effects result from breathing for a long time air loaded with the effluvia. The plant varies in narcotic power according to the weather and climate, being most active in hot and dry seasons and in warm countries.

All parts of the plant contain the toxic principle and the leaves were at one time recognized by the British Pharmacopœia. Because of the rapidity of their deterioration, however, they were never satisfactory. The fruits (sometimes, incorrectly, called the seed) retain their activity much longer than the leaves. Conium fruits should be collected from plants fully grown but before their color changes from green to yellow, and thoroughly dried.

The commercial supplies of conium are from Europe. Commercial conium occasionally contains other umbelliferous plants, or it may be almost wholly composed of such plants, and even anise has been used as an adulterant of the fruit. (See *Anise.*)

Description and Physical Properties.—"*Unground Conium.*—Broadly ovoid, greenish gray, the two mericarps often separated, each about 3 mm. long and about 1.5 mm. in diameter, ovoid, somewhat curved; the inner flattened side marked by a deep longitudinal groove; the outer convex side with five, pale yellow, somewhat crenate ribs; the intervening surfaces wrinkled; pericarp without oil-tubes. Odor slight, but when triturated with a solution of potassium hydroxide T.S., strong, disagreeable, and mouselike; taste characteristic, disagreeable, afterwards somewhat acrid.

"*Structure.*—Transverse sections of the mericarp pentangular in outline, the angles projecting and forming the ribs, four of the sides being almost equal in length, the fifth or commissural side being about twice as long as one of the dorsal sides and usually concave near the middle; a distinct fibro-vascular bundle at each angle composed of thick-walled fibers about 0.013 mm. in diameter and a few tracheæ; epidermis consisting of one layer of cells, without hairs; pericarp thin, without oil-tubes, enclosing a single seed and extending inwardly on the commissural side for about one-third the diameter of the section; endocarp composed of two layers of cells with yellowish brown walls, the outer layer with cells from 0.060 mm. to 0.140 mm. in tangential length and with thickened radial and inner walls, the inner layer with thin-walled cells from 0.030 to 0.080 mm. in tangential length and about 0.030 mm. in radial diameter; the seed coat composed of small thick-walled cells about 0.015 mm. in radial diameter, often obliterated; a large endosperm somewhat pentangular-rounded in outline, with a deep channel on the commissural side and composed of polygonal parenchyma cells, the latter containing globules of fixed oil and aleurone grains with rosettes of calcium oxalate.

"*Powdered Conium.*—Greenish gray; numerous angular or rounded, light colored fragments of endosperm tissue, composed of parenchyma cells containing fixed oil, aleurone grains and rosettes of calcium oxalate, the latter from 0.002 to 0.008 mm. in diameter; a few more or less curved groups of lignified fibers; fragments of the seed-coat with yellowish brown walls; a few rounded starch grains about 0.005 mm. in diameter; spiral or annular tracheæ few; numerous oil globules separate on mounting the powder in chloral hydrate T.S.

"**Assay.**—Place 15 Gm. of Conium, in a moderately fine powder, in a 250 cc. flask or bottle, add 150 cc. of purified petroleum benzin, allow to stand five minutes, then add 15 cc. of solution of sodium hydroxide U.S.P., stopper securely and shake the flask vigorously at intervals during two hours. Allow it to stand over night and again agitate vigorously at intervals during one hour. Allow the mixture to settle, decant 100 cc. of clear fluid (representing 10 Gm. of Conium) and extract the alkaloids from this by shaking out with successive portions of weak hydrochloric acid, until a few drops of the acid washings give no test for alkaloid with iodine T.S. Evaporate the combined acid washings on a water-bath to a volume of about 10 cc., cool and transfer to a separator and render it alkaline by the cautious addition of sodium carbonate. Extract the alkaline liquid with successive small portions of purified petroleum benzin until a portion gives no test for alkaloid with iodine T.S., and to the combined benzin washings add 10 cc. of tenth-normal sulphuric acid. Stir thoroughly during two minutes, to bring the acid in contact with the benzin solution, then evaporate the benzin layer in a current of warm air. Titrate the acid solution, using cochineal T.S. or methyl red T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to 0.0126 Gm. of coniine." *N. F.*

The active principle seems to be most abundant in the seeds. Even these, however, deteriorate rapidly when kept. Farr and Wright (*P. J.*, Feb., 1904) found the average alkaloidal content of fresh seed to be 2.13 per cent. and of the commercial dried seed, 0.674 per cent. The N. F. requires not less than 0.5 per cent.

Constituents.—In the root Harley found three proximate principles, a bitter resin, which he names *conamarine,* and two crystallizable bodies, named respectively *rhizoconin,* and *rhizoconolein.* They are all neutral, and, so far as known, medicinally inert. (See *P. J.*, Aug., 1867.)

The activity of conium is due to the presence of five alkaloids which are as follows:

Coniine, the most important of these, was discovered in 1827, by Giesecke. The formula, $C_8H_{17}N$, is universally accepted; it is a propylpyridine. When pure it is a colorless, strongly alkaline liquid with a peculiar odor, similar to that of the plant. It boils at 166°–167° C. and solidifies at –2° C. It is naturally dextrorotatory but l-coniine has been prepared. It forms crystalline salts with a number of acids. Coniine has been prepared synthetically by several authors in various manners (see Ladenburg, *B. Chem. G.*, 1907, xl; Lautenschlager and Onsager, *B. Chem. G.*, 1918, li). Hess and Eichel (*B. Chem. G.*, 1917) have shown that pelletierine of pomegranate, is an aldehyde of coniine. Coniine is freely soluble in alcohol, ether, and the fixed and volatile oils, and slightly so in water. It unites with about one-fourth of its weight of water to form a hydroxide. Like ammonia, it occasions a white cloud when approached by a rod moistened with hydrochloric acid; and the resulting hydrochloride is crystallizable, and not in the least deliquescent. When exposed to the air, coniine speedily assumes a deep brown color, and is ultimately converted into a resinous matter, and into ammonia, which escapes. Under the influence of heat this change takes place with much greater rapidity. The presence of coniine may be detected in an extract or other preparation of hemlock by rubbing it with potassium hydroxide, which instantly develops its peculiar odor. It is a most energetic poison.

Methyl-coniine (N-methyl-*d*-coniine), $C_8H_{16}N.CH_3$, occurs in very small amounts. It is a colorless oily liquid, boiling point 173°–174° C., more strongly dextro-rotatory than coniine (see Braun, *B. Chem. G.*, 1905 and 1917, l).

Conhydrine, discovered by Wertheim in 1857, is an oxygenated base with the formula $C_8H_{17}ON$. It is crystalline, melting at 121° C. Isomeric with it is *pseudo-conhydrine* (see Loffler, *B. Chem. G.*, 1909) which has a melting point of 105°–106° C.

Conieine, $C_8H_{15}N$.—A series of isomers have been prepared by chemists, in various ways, from coniine. Of these bases at least one—gamma-coniceine—appears to occur in the natural drug. (Wolffenstein, *B. Chem. G.*, 1895; see also Loffler, *B. Chem. G.*, 1909, xlii) but has been formed by the action of fuming hydrochloric acid on conhydrine. It is a coniine-like oily liquid almost insoluble in water, strongly alkaline and optically inactive. All of these alkaloids seem to be similar in their physiological effects (Albahare and Loffler, *C. R. A. S.*, 1908, cxlvii, p. 996). Gamma-coniceine is the most toxic, coniine the next and conhydrine the least.

Uses.—Hemlock or conium is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect until Störck employed and extravagantly praised it. Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep.

The alkaloids of conium all have the same physiological properties, although there is a difference in the degree of their power. Their most important effect is a paralysis of the peripheral endings of the motor nerves. In the account of the death of Socrates reference is made to loss of sensation as one of the prominent symptoms of his poisoning and there is evidence that the drug has an effect upon the sensory as well as upon the motor nerves, but the dominant action is certainly upon the motor system. Hayashi and Muto (*A. E. P. P.*, 1901, xlviii) have shown that the phrenic nerve is more susceptible to the drug than the other motor nerves of the body. It is evident, therefore, that if given in sufficient dose to control spasms, conium would stop the movements of the diaphragm and therefore cause death through asphyxia.

The drug has, however, been used in spasmodic disorders, such as *whooping cough, paralysis agitans,* and *acute mania* and by some with asserted good results. It was in the days of superstitious medicine believed to exercise an alterative effect in *scrofulas* and similar diatheses, but was long ago abandoned for this purpose.

Coniine acts precisely as does hemlock, and may be used for the same purposes. The *dose* is from one-fortieth to one-twelfth of a grain (0.0015–0.005 Gm.). Its solution has been used locally in the spasmodic contraction of the *orbicularis oculi* and *ophthalmia* with *photophobia* in scrofulous children. For these purposes from one-half to one per cent. may be employed. Various salts have been prepared, but the *hydrobromide* is the one most frequently used.

This occurs in colorless prismatic needles, soluble in water and alcohol, less so in ether and chloroform, inodorous and almost tasteless, and are not deliquescent. It should be kept in the dark, otherwise it assumes a red tint.

Dose, of conium, three to five grains (0.2 to 0.32 Gm.).

Off. Prep.—Extractum Conii, *N. F.*

CONVALLARIÆ RADIX. N. F.

CONVALLARIA ROOT Convall. Rad.

[Lily-of-the-Valley Root]

"Convallaria Root consists of the dried rhizome and roots of *Convallaria majalis* Linné (Fam. *Liliaceæ*). Convallaria Root contains not more than 5 per cent. of leaves or other foreign organic matter and yields not more than 6 per cent. acid-insoluble ash." *N. F.*

Lilium Convallium; Muguet, *Fr.*; Maiblumen, *G.*; Mughetto, *It.*; Convalaria, Lirio de los valles, *Sp.*

Convallaria majalis L. is a low, acaulescent, perennial herb native to mountainous regions of Europe, Asia and Southeastern United States. It is widely cultivated for the beauty and fragrance of its flowers. Its above ground portion first exhibits two to three oblong, parallel-veined leaves and later a slender one-sided raceme of small, white, nodding bell-shaped flowers. The fruits are red berries.

Both the root and flowers were formerly official but the N. F. V recognizes only the rhizome and roots.

Description and Physical Properties.—"*Unground Convallaria Root.*—Rhizome horizontal, elongated, usually branched cylindrical, variable in length, from 1 to 3 mm. in diameter; externally yellowish white or pale brown, with a few circular stem scars, and from 3 to 5 thin, tortuous, dark brown, branching roots arising from the lower portions of the nodes; fracture short or fibrous; internally whitish. Odor faint; taste sweetish, becoming bitter and acrid.

"*Structure.*—Rhizome; an epidermis with a thick outer layer of cutin; a hypodermal layer of a single row of collenchyma; a cortex made up of about twenty rows of parenchyma cells, some of which contain starch and others raphides of calcium oxalate; a prominent endodermis, the radial and inner walls, strongly thickened and lignified; inside the endodermis an interrupted circle of collateral fibro-vascular bundles, the woody portion V shaped in cross section; inside the first circle of bundles, another interrupted circle of fibro-vascular bundles of the concentric type, the sieve tissue being surrounded by the xylem; parenchyma cells of the pith separated by large inter-cellular spaces. The root shows a hairy epidermal layer; a hypodermis of a single row of cells; a cortex of about six rows of cells, some of which contain starch or raphides of calcium oxalate, and oil; the cells of the endodermal layer resemble those of the rhizome; fibro-vascular bundles mostly five.

"*Powdered Convallaria Root.*—Brown; tending to cake on standing; a few simple or compound starch grains the latter, the simple grains nearly spherical and from 0.003 to 0.012 mm. in diameter; raphides of calcium oxalate few, from 0.020 to 0.060 mm. in length, rarely up to 0.150 mm.; cells of endodermis with slightly oblique ends and considerably thickened, lignified porous walls; fragments of tracheæ with spiral and scalariform thickenings, or with porous walls." *N. F.*

G. F. Walz found in lily of the valley two glucosides, *convallarin* and *convallamarin.* (*A. J. P.*, 1859, p. 577.) Convallarin is in colorless, rectangular prisms, scarcely soluble in water, but sufficiently so as to render the solution acrid. It is decomposed by long boiling with diluted acids into sugar and *convallaretin.* J. Lindner (*J. P. C.*, 1916, xiii, 290) examined convallarin of commerce. He finds it has the formula $C_{22}H_{40}O_{10}$ and not the formula ($C_{34}H_{62}O_{11}$) ascribed to it by its discoverer. According to Kobert convallarin is related to the saponins. Convallamarin is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. Its composition is $C_{23}H_{44}O_{12}$, and it is decomposed by heating with diluted sulphuric acid into sugar and *convallamaretin.* For preparing convallamarin, Tanret modifies Walz's method, as follows. An alcoholic tincture made from the whole plant is precipitated with lead subacetate and filtered; the excess of lead is removed with diluted sulphuric acid, avoiding the use of more than is necessary, and, after neutralizing, the tincture is distilled, the last portion of alcohol being driven off in the open air, then the cooled and filtered liquor is treated with tannin, care being taken to keep the liquid neutral by cautiously adding a diluted solution of sodium carbonate. A compound of tannin and convallamarin is precipitated, which, after washing, is dissolved in 60° alcohol, the solution decolorized with charcoal, decomposed with zinc oxide, filtered, and evaporated to dryness. In this way convallamarin is obtained nearly white. To free it from the salts that are sometimes carried down by the tannin precipitate, it is a good plan to redissolve it in 90° alcohol, filter, and then evaporate. One kilogramme of the fresh plant collected in the first days of August yielded two grammes of convallamarin. (*P. J.*, 1882, p. 423.)

Uses.—Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the *dose* of half a drachm. They were formerly used in *epilepsy* and against *worms.* The root, which is also bitter, has similar purgative properties, and in powder is said to be sternutatory. Convallaria, like digitalis, in moderate doses slows the pulse rate and in toxic doses stops the heart in systole and has been used in the treatment of *heart disease.* Marvin and White (*J. A. M. A.*, 1921, lxxvii, p. 1868), however, found that in *auricular fibrillation,* although it produced the ventricular slowing characteristic of the digitalis group, in the majority of cases it failed to lead to any clinical improvement.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Fluidextractum Convallariæ Radicis, *N. F.*

COPAIBA. U. S., Br.

COPAIBA Copaib. [Balsam Copaiba]

"An oleoresin derived from South American species of *Copaiba* (Fam. *Leguminosæ*)." *U. S.* "Copaiba is the oleo-resin obtained by incision from the trunk of various species of Copaifera, *Linn.*" *Br.*

Balsamum Copaiferarum; Balsam of Copaiba, Balsam Capivi; Copahu, *Fr. Cod.;* Baume de Copahu, *Fr.;* Balsamum Copaïvæ, *P. G.;* Copaiva; Copaivabalsam, *G.;* Balsamo d Copaive, *It.;* Oleoresina de Copaiba, Bálsamo de Copaiva, *Sp*

Copaiba was first noticed in a work published by Purchas, in England, in 1625. It is derived from several South American trees of the genus *Copaiba* Mill. (*Copaifera,* L.). The most important of these are: *C. officinalis* (L.) Jacquin, *C. guyanensis* (Desf.) O. Kuntze, *C. Langsdorffii* (Desf.) O. Kuntze, and *C. coriacea* (Mart.) O. Kuntze.

The plants yielding the drug are large, much branched trees having in their full grown condition huge trunks. The branches have smooth bark and bear alternate, paripinnate leaves, each with 6 to 10 entire, ovate, coriaceous pellucid-punctate leaflets. The flowers are small and white, each with a receptacle bearing 5 sepals, 10 stamens and a monocarpellary pistil. The fruit is a one-seeded legume.

Copaiba is considered a morbid product of the cell walls of the wood parenchyma. It accumulates in cavities, within the trunk of the tree, that enlarge and join to form great reservoirs, the latter often holding several gallons of oleoresin.

The juice is obtained by making a square chamber in the trunks of the trees, reaching to the very center; and the operation is said to be repeated several times during the same season. It is asserted that single trees have yielded as much as forty liters. As it flows from the wound, it is clear, colorless, and very thin, but it soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranham, in Brazil, and is brought to this country from the port of Para, in small casks or barrels. Smaller quantities of it come from Maracaibo, in Venezuela, and from other ports on the Caribbean Sea, whence it is brought in casks, demijohns, cans, jugs, etc.

C. officinalis is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique. This is the source of the Maracaibo or Venezuela copaiba, which is also obtained in part from *C. guianensis.* This variety of copaiba is distinguished by being lævogyrāte, more viscid and darker in color.

Numerous varieties of true South American copaiba exist in commerce, known under the name of the various ports of shipment. The most important of these varieties besides Maracaibo is the Para or Maranham copaiba, which is derived from *C. Langsdorffii* and *C. coriacea,* which is characterized by being optically lævogyrate. The other varieties are Bahia, Carthagena, Maranham, and Cayenne. Each one of these varieties has been referred (see *P. J.,* 1901, lxvi, 325) to a special species of the genus Copaiba, but there is little reason for supposing that this reference is accurate, and there is much reason for believing that various trees contribute to a single variety of copaiba.

Most of our copaiba is either of the Maracaibo or Para varieties. Although the individual specimens from each of these regions differ so much among themselves that it is impossible to draw a sharp distinction in the physical properties between the two varieties, the Para variety is generally comparatively low in proportion of resin, consisting of from 55 to 90 per cent. of volatile oil. Because of the large proportion of oil the Para copaiba is more liquid and of a lower specific gravity than that which comes from Maracaibo. Much of the Para copaiba fails to meet the pharmacopœial requirements in the percentage of resin and specific gravity. The U. S. requires a specific gravity of 0.94 or over and not less than 36 per cent. of resin; The Br. requires a specific gravity of 0.975 to 0.995 and about 55 per cent. of resin.

According to E. Keto, copaiba of Maracaibo has a density of 0.999; a coefficient of acidity of 85.4; of etherification of 6.7; while that of Para has a density of 0.92; a coefficient of acidity of 19.4; of etherification of 7.4.

The German Pharmacopœia requires that the specific gravity shall be 0.98 to 0.99, and that the acid number shall fall between 75.6 and 84, and the ester number be not more than 8.4.

Surinam copaiba is a yellowish or brownish-yellow liquid, of varying consistence; it may be distinguished from Maracaibo copaiba by the fact that one drop of it dissolved in 1 cc. of acetic anhydride gives a fine blue color on the addition of a drop of sulphuric acid. (*P. J.,* Nov., 1904.)

African copaiba, or *Balsam of Illurine,* which reached the London market first in 1891, from West Africa, is a brownish substance, having a consistency similar to the Maracaibo copaiba, and a greenish fluorescence. Its aromatic odor is entirely different from that of copaiba; its taste is biting, with an after-taste of bitterness. According to Keto (*J. P. C.,* 1902, 381), its density is 0.9905; its coefficient of acidity 55.5; of etherification 8.3. It is soluble in chloroform and petroleum benzin, also in ether, with which it makes an opalescent liquid. Its solution in absolute alcohol, or alcohol of 95 per cent. is not limpid. From it Keto separated *illurinic acid.* Its volatile oil is of a pale yellow color, with a strong odor entirely different from that of copaiba. The residue which remains after the distillation consists of two resins, one soluble, the other insoluble, in alcohol. This oleoresin probably is the product of *Hardwickia Mannii* Oliver, a tree closely allied to the true copaibas. (See *Ap. Ztg.*, 1894, p. 9.) J. C. Umney (*A. J. P.*, 1893, 544) found in African copaiba 39 per cent. of an oil of 0.918 specific gravity and with a rotation of + 20° 42′, the last character distinguishing it from the other varieties which yield lævorotatory oils.

Solid Copaiba or *Mass of Copaiba* is official in the National Formulary, Part III. See also U. S. Dispensatory, 19th edition, p. 398.

Description and Physical Properties.—"A pale yellow to brownish-yellow, more or less viscid liquid, either without fluorescence or with only a slightly greenish fluorescence. It has a peculiar, aromatic odor, and a persistent, bitter, acrid taste. Copaiba is insoluble in water, partly soluble in alcohol, more completely soluble in dehydrated alcohol. It is soluble in carbon disulphide and in fixed or volatile oils, completely soluble in chloroform and in ether; also soluble in an equal volume of petroleum benzin, the further addition of the solvent producing a flocculent precipitate.

"Specific gravity: 0.940 to 0.995 at 25° C. Heat about 2 Gm. of Copaiba, accurately weighed, in a shallow dish on a water bath: no odor of oil of turpentine is evolved. Continue the heating until all of the volatile oil has been driven off: a resin remains, corresponding to not less than 36 per cent. of the original weight of the Copaiba taken. This resin when cooled is hard and brittle (*paraffin or fatty oils*). Its acid number is not less than 28 and not more than 95, page 427. Shake 5 cc. of Copaiba with 15 cc. of alcohol, boil the mixture for one minute, and cool: no oil separates after standing for one hour (*paraffin oils*). Mix one drop of nitric acid and 3 cc. of glacial acetic acid in a test tube, and carefully add four drops of the oil separated from the Copaiba by distillation with steam: no reddish zone appears, nor does the liquid become red or purple after being shaken (*gurjun balsam*). Dissolve 2 Gm. of Copaiba in 40 cc. of dehydrated alcohol, filter on counterbalanced filters or with the aid of a Gooch crucible, and wash with small portions of dehydrated alcohol until the washings are colorless or nearly so: the residue dried at 80° C. does not exceed 5 per cent. The volatile oil separated from Copaiba by distillation with steam does not boil below 250° C., and shows an angle of rotation in a 100 mm. tube of not less than –7° at 25° C. (*African copaiba*)." *U. S.*

"A more or less viscous liquid, generally transparent and occasionally fluorescent, yellow to golden brown. Specific gravity 0.975 to 0.995. Entirely soluble in *absolute alcohol;* soluble in four times its volume of *petroleum spirit*, the solution yielding only a slight filmy deposit on standing. Aromatic, characteristic odor; taste acrid, somewhat bitter, persistent. Loses about 45 per cent. of its weight when heated for forty-eight hours to 100° C. Forms a transparent solution with one-third of its volume of *solution of ammonia.* Four drops carefully added to a mixture of 5 millilitres of *glacial acetic acid* with four drops of *nitric acid* do not yield a purplish or violet color (absence of gurjun balsam). One gramme dissolved in 25 millilitres of *absolute alcohol,* requires for neutralisation not less than 2.7 millilitres of *N/2 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (presence of a due proportion of acid resins). The volatile oil distilled from it responds to the tests described under 'Oleum Copiabæ.'" *Br.*

Copaiba, upon exposure to the air, acquires a deep color, a thicker consistence, and greater density, and; if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization and partly to the oxidation of the essential oil. As it is the soft resin that results from the oxidation of the oil, it follows that the proportion of this resin increases with age. Considerable diversity must, therefore, exist in the drug, and in its physical properties and in the proportions of its ingredients, according to its age and degree of exposure. Similar difference also exist in the copaiba procured from different sources. It is not impossible that differences may exist in the drug according to the circumstances of its collection. The species of *Copaiba* from which the oleo-resin is collected, as well as the age of the tree, its position, and the season of collection, must also have influence over the product. It is highly probable that the resinous matter results from the oxidation of the oil in the cells of the plant, and that the less elaborated the oleoresin may be, the larger proportion it will contain of the oil. It is said that a volatile oil flows abundantly from a tree near Bogotá, which is employed to adulterate the copaiba collected in that vicinity and shipped from Maracaibo and other neighboring ports.

Copaiba is often adulterated. The substances most frequently used for this purpose are: (1) Some fixed oil, especially castor oil, as this cannot be distinguished by its insolubility in alcohol. (2) Gurjun balsam (see *Oil of Wood,* Part II). (3) Volatile oils, especially oil of turpentine or of sassafras. (4) Colophony. (5) Liquid petroleum. Most of these adulterants are excluded by the requirements of the U. S. P.

For additional tests and criticisms by Beckurts and Brueche, see *A. Pharm.*, 1891, p. 90; also *Proc. A. Ph. A.*, 1892, 635. For Hager's test, see *C. D.*, 1894, 740. Dodge and Olcott (*Am. Drug.*, 1895, 5) describe a test to detect gurjun balsam in copaiba, which Kebler regards as the most reliable yet proposed; it is as follows. Four drops of the suspected sample, dissolved in half a fluidounce of glacial acetic acid, will, if pure, remain colorless and clear, or but slightly cloudy, if from four to six drops of pure nitric acid be dropped into the solution.

If the sample be pure gurjun balsam, the mixture will have a deep purple color; if a mixture of the two balsams, the depth of color will vary according to the amount of the adulterant, as small a proportion as 2 per cent. being discoverable; a modification of this test is now official. (See also *A. J. P.*, 1896, 143, and 1897, 394.) For a valuable paper on Copaiba by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1904, 322.

Constituents.—The essential ingredients are volatile oil and resin, with at times small quantities of acid. As it contains no benzoic acid, it cannot properly be called *balsam of copaiba*. The substances which it most closely resembles, both in composition and in properties, are the turpentines. (See *Oleum Copaibæ*.) For a description of an apparatus for distilling the volatile oil, see a paper by R. A. Cripps in *C. D.*, 1892, 282. The proportion of oil varies greatly, ranging from 30 to 75 per cent.

The *resinous* mass which remains after the distillation of the oil is hard, brittle, translucent, greenish-brown, and nearly destitute of odor and taste. It is of an acid character, and yields a series of amorphous salts; it may be obtained pure by exposing a mixture of 9 parts of copaiba and 2 parts of aqueous ammonia (sp. gr. 0.95) to a temperature of 10° C. Tschirch (*Harze and Harzbehälter*, 1900, p. 297) obtained from Maracaibo balsam a crystalline resin acid corresponding in many respects with Strauss's metacopaivic acid, to which, however, he gave the formula $C_{11}H_{16}O_2$, finding a melting point 89° to 90° C. as against 205° to 206° C. for Strauss's acid. Para balsam was found by Tschirch to contain two crystallizable resin acids together with several uncrystallizable ones. Illurinic acid has also been reported in Maracaibo balsam. Keto (*J. P. C.*, 1902, p. 381) finds in Para balsam the two crystallizable acids referred to above, one of which he names *paracopaivic acid* with the formula $C_{20}H_{32}O_3$ and fusing point 142° to 145° C., and the other *homoparacopaivic acid*, $C_{18}H_{28}O_3$, fusing at 111° to 112° C. To *illurinic acid* mentioned by Tschirch he gives the formula $C_{20}H_{28}O_3$ and the melting point 128° C.

For description of the volatile oil see *Oleum Copaibæ*.

Uses.—Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to the whole mucous membrane, for which it appears to have a strong affinity. The urine acquires a peculiar odor during its use, and its odor may be detected in the breath. It sometimes occasions an eruption upon the skin resembling that of measles, and attended with disagreeable itching and tingling; in rare instances vomiting, painful purgation, stranguary and bloody urine, and a general state of fever are caused by excessive doses.

As a remedy it has been found useful in *catarrhs*, particularly those of a chronic character. Thus, it is given with occasional advantage in *leucorrhea, chronic cystitis, chronic diarrhea, hemorrhoids,* and *chronic bronchitis.* The complaint, however, in which it is most employed is *gonorrhea.* It should not be administered in the first stages, when the inflammation is severe and acute, nor is it applicable to very chronic forms of the disorder, such as gleet. It was formerly much esteemed as a vulnerary and as an application to *ulcers,* but it is now seldom used externally. Ruschenberger recommends it locally in *chilblains.*

Both the volatile oil and the resin are eliminated by the kidneys in an altered condition; if to the urine of a person taking the drug, nitric acid be added, a precipitate is thrown down, which may be mistaken for albumin. The volatile oil is more active than is the resin, which is not, however, inert.

It may be given dropped on sugar, but in this form is often so exceedingly offensive as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, sweetened with sugar and flavored with some aromatic water, as that of mint or cinnamon.

Dose, of copaiba, from fifteen minims to a fluidrachm (1.0–3.75 cc.) three times a day, or a smaller quantity repeated more frequently.

Off. Prep.—Massa Copaibæ, *N. F.;* Mistura Copaibæ, *N. F.;* Mistura Copaibæ et Opii, *N. F.;* Oleum Copaibæ, *Br.*

COPTIS. N. F.

COPTIS [Goldthread]

"Coptis is the dried plant of *Coptis trifolia* (Linné) Salisbury (Fam. *Ranunculaceæ*). Coptis contains not more than 3 per cent. of foreign organic matter." *N. F.*

Coptide, *Fr.;* Gelbe (Kleinste) Niesswurz, *G.*

Coptis trifolia (L.) Salisbury is a low perennial herb characterized by having a slender (filiform) orange-colored rhizome from which spring several radical, evergreen, long-petioled, trifoliate leaves and a slender scape terminating in a single white flower which opens from May to July. The fruit consists of seven follicles containing small black seeds. This plant inhabits the northern region of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and alpine regions, and abounds in Canada and in the hilly districts of the Northern United States.

Description and Physical Properties.—"*Unground Coptis.*—In loose, matted masses consisting of long, much branched rhizome and small roots, together with the leaves; rhizomes orange or golden-yellow; leaves evergreen, long and slenderly petioled, trifoliate, the segments broadly obovate-cuneate, crenately lobed and toothed with sharp-pointed teeth, prominently veined, smooth, coriaceous, dark green and shining but often drying to a dull brownish hue; flowers, if present, small, solitary, terminating slender scapes; sepals 5 to 7, oblong, obtuse, deciduous; petals 5 to 6, pale yellow, small, club-shaped; stamens numerous. Odor faint; taste purely bitter without astringency.

"*Powdered Coptis.*—Yellowish green; exhibits numerous, mostly simple, starch grains, somewhat rounded, up to 0.007 mm. in diameter; fragments of leaf epidermis, composed of cells with wavy vertical walls and broadly elliptical stomata, the latter up to 0.024 mm. long; fragments of the nerved scales from the nodes, composed of cells with yellow walls; leaf parenchyma cells containing chloroplastids; few simple, thick-walled hairs from the midrib of the leaf, from 0.035 to 0.075 mm. long; elongated, epidermal cells from the roots having yellow walls and filled with reddish contents; fragments of epidermal and sub-epidermal cells from the rhizome, similar to those from the root, but without reddish contents, though often with yellowish content; groups of elongated parenchyma cells about 0.060 mm. long and about 0.010 mm. wide, many of the cells being filled with starch grains; tracheæ about 0.020 mm. wide; with bordered pores or spiral markings; narrow thin-walled, porous fibers." *N. F.*

It imparts a bitterness and yellow color to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. The infusion is precipitated by silver nitrate and lead acetate. It affords no evidence of either resin, gum, or tannin. The plant contains berberine, which appears to be associated with another alkaloid. Gross states that the second alkaloid, which he calls *coptine,* differs from berberine in its colorless crystals, and by forming with mercuric potassium iodide (Mayer's reagent) a crystalline instead of flocculent precipitate. (See also John J. Schulz, *A. J. P.,* 1884, 261.)

Uses.—Goldthread is a simple bitter tonic. In New England it is employed as a local application in *aphthous ulcerations* of the mouth, but it probably has no other virtues in this complaint than such as are common to the simple bitters. It may be given in substance, infusion, or tincture.

The *Coptis Teeta* of Wallich, which grows in the mountainous regions bordering on Assam, the *C. trifolia* Salisb. of India, and the *C. anemonefolia* Sieb. et Zucc. of Japan, also contain berberine and have been used as gastrointestinal tonics.

The *dose* of the powder is from ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Fluidextractum Coptis, *N. F.*

CORIANDRUM. N. F. (Br.)

CORIANDER Coriand. [Coriander Seed]

"Coriander is the dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*). Coriander contains not more than 5 per cent. of other fruits, seeds, or other foreign organic matter and yields not more than 1.5 per cent. of acid-insoluble ash, nor less than 0.5 per cent. of volatile ether-soluble extractive." *N. F.* "Coriander Fruit is the dried ripe fruit of Coriandrum sativum, *Linn.*" *Br.*

Coriandri Fructus, *Br.;* **Coriander Fruit; Coriandre, Coliander,** *Fr. Cod.;* **Koriander,** *G.;* **Coriandro,** *It.;* **Cilantro** *Sp.*

Coriandrum sativum is an annual plant, with an erect branching stem rising about two feet, and furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes like those of parsley. The flowers are white or rose-colored, and in compound terminal umbels; the fruit globular, and composed of two concavo-convex mericarps. *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extended cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the official portion.

Coriander is cultivated in India, Asia Minor, northern Africa and the United States. The plants are propagated from seeds sown in the spring. In August and early September, when the fruits are ripe, the plants are mowed down, partially cured in the field and dried under cover. The fruits are then thrashed out and cleaned. The chief supplies come from Tangier, Morocco and from Marseilles, France. Attempts have been made to cultivate the plant in Vermont.

Description and Physical Properties.—"*Unground Coriander.*—Mericarps usually coherent; cremocarp nearly globular, from 2 to 5 mm. in diameter; externally light brown or rose colored; apex with 5 calyx teeth and a short stylopodium, each mericarp with 5 prominent, straight, longitudinal primary ribs and 4 indistinct, undulate secondary ribs; mericarps easily separated, deeply concave on the inner or commissural surface.

"*Structure.*—An epidermis of small cells with thick walls; a layer of several rows of thin-walled, more or less collapsed parenchyma separated from a broad zone of strongly lignified fibers which extend as a continuous layer in the mesocarp of each of the mericarps; 2 or 3 layers of large, tangentially elongated, thin-walled parenchyma cells, frequently with numerous large, intercellular spaces and bearing on each commissural side 2 large, elliptical oil-tubes; endocarp of large tabular cells, the inner yellowish walls being considerably thickened and closely coherent to the brownish cells of the seed-coat, except on the commissural side where the endocarp is separated from the seed-coat forming a large elliptical cavity; endosperm distinctly reniform in outline and consisting of tabular or polygonal thick-walled cells containing fixed oil, and numerous large aleurone grains each with a rosette or prism of calcium oxalate.

"*Powdered Coriander.*—Light brown, consisting chiefly of endosperm and lignified tissues of the pericarp; calcium oxalate crystals numerous, from 0.003 to 0.010 mm. in diameter, mostly in rosettes, either isolated or in aleurone grains; fibers irregularly curved, having thick, yellowish, lignified walls and numerous simple pores; numerous globules of fixed oil; few fragments of light yellow oil-tubes, associated with elongated polygonal epidermal cells." *N. F.*

"Nearly globular, about five millimetres in diameter, uniform brownish-yellow in color, and glabrous. Mericarps usually closely united, and crowned by the calyx teeth and stylopod. Primary ridges wavy and inconspicuous; secondary ridges straight and more prominent. In transverse section, two vittæ on the commissural surface of each mericarp. Aromatic odor, especially when bruised; taste agreeable." *Br.*

The aromatic taste and odor of coriander depend on a *volatile oil* (see *Oleum Coriandri*), which may be obtained separate by distillation. One pound of the seeds yields forty-two grains of the oil. (Zeller.)

The drug not infrequently contains a large admixture of earthy and stony substances as well as stems and similar inert matter. Blome reports finding a sample of coriander that contained 20 per cent. of flaxseed. LaWall has found leguminous starch in a specimen of powdered coriander, probably from vetch seed which is sometimes accidentally present.

Uses.—Coriander is a rather feeble aromatic. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients.

Dose, twenty to sixty grains (1.3–3.9 Gm.).

Off. Prep.—Confectio Sennæ, *Br.;* Syrupus Rhei, *Br.;* Tinctura Rhei Composita, *Br.;* Tinctura Sennæ Composita, *Br.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

CORNUS. N. F.

CORNUS [Dogwood Bark]

"Cornus is the dried root bark of *Cornus florida* Linné (Fam. *Cornaceæ*). Cornus contains not more than 5 per cent. of adhering wood or not more than 2 per cent. of other foreign organic matter." *N. F.*

Flowering Dogwood; Flowering Cornel; Cornouiller à grandes fleurs, *Fr.;* Grossblüthige Cornelrinde, *G.*

Cornus florida L. or Flowering Dogwood is a small tree usually 15 to 25 feet high, a native of the woods of the eastern and central United States. It is readily distinguished by its opposite branches, alligator bark, bright red or occasionally greenish twigs, small lateral buds that are covered by the persistent bases of leaf stalks, large spherical flower-buds and terminal leaf-buds with a single pair of bud-scales. Its leaves are opposite, simple, ovate, acute at apex, cuneate at base, entire to wavy along margin and with very prominent midrib and lateral veins. Its flowers appear during April. Each so-called "flower" is in reality a glomerule consisting of a dense cluster of small, greenish florets imbedded on a compound receptacle that is surrounded by a white involucre of four obcordate bracts. The fruit appears in autumn as a scarlet, ovoid drupe.

The barks of two other indigenous dogwoods were formerly substituted for that of *C. florida* L. Each of these is a shrub with opposite leaves, the flowers in flat spreading cymes, and the fruit globular and bright red. *C. circinata* L'Her. is further distinguished by its long branches being greenish and warty; its leaves round-oval, abruptly pointed, and woolly underneath. *C. Amomum* Mill. (*C. sericea* L.), *Silky Cornel* or *Swamp Dogwood,* is to be recognized by its purplish branches, and by the fact that the branchlets, stalks, and lower surface of the elliptical pointed leaves are silky and downy. (See also *Chem. News,* 1908, 191.)

These dogwoods are found in all portions of the United States east of the Mississippi.

Description and Physical Properties.—"*Unground Cornus.*—In irregular, chip-like pieces, or portions of quills, usually less than 5 cm. in length; bark from 1 to 4 mm. in thickness; externally scaly and of a dingy-brown color, with few minute root scars or finely roughened; and of a reddish color where the corky layers have been removed; heavy cork patches wanting (absence of trunk bark); inner surface varying from pinkish brown to reddish brown, roughened from numerous short striæ; fracture short, the broken surface purplish or pinkish white and roughened from light-colored projecting groups of stone cells. Odor slight; taste bitter and astringent.

"*Structure.*—Outer bark of several layers of more or less exfoliating cork cells; middle bark of tangentially elongated parenchyma cells, many of which contain rosettes or prismatic crystals of calcium oxalate, a few with starch grains; inner bark with nearly straight medullary rays up to 10 cells wide, some of which extend nearly to the cork and separated by sieve tissue, parenchyma cells and non-lignified fiber-like cells, many of the latter having large simple pores and exhibiting distinctly beaded radial walls when examined in tangential section; many of the parenchyma cells, particularly of the medullary rays contain rosettes or prismatic crystals of calcium oxalate, others contain a brownish amorphous substance; stone cells either isolated or in groups, the individual cells often with branching pores and a reddish brown amorphous content, some with thinner walls, usually non-porous containing one or more prisms of calcium oxalate; lignified bast-fibers are absent.

"*Powdered Cornus.*—Numerous fragments of small thin-walled, non-lignified fibers and parenchyma cells, the latter often containing a brownish or purplish brown amorphous substance, many of the fragments becoming distinctly purplish pink upon mounting in chloral hydrate T.S.; stone cells isolated and in groups, the individual cells up to 0.125 mm. in length; numerous prism and rosette crystals of calcium oxalate up to 0.060 mm. in diameter, the prisms frequently occurring in stone cells; starch grains few, simple or 1- to 3-compound, rounded to oval or narrowly elliptical in outline, usually 0.003 to 0.025 mm. in length, occasionally larger; few fragments of cork, the cells containing a brownish pigment; lignified fibers and tracheæ very few or wanting (absence of trunk bark and wood)." *N. F.*

Geiger in 1836 obtained from dogwood a bitter principle, *cornin* (or *cornic acid*), concerning which, however, there does not appear to be any recent information. C. F. Kramer (*A. J. P.*, 1882) found in the bark about 3 per cent. of tannic acid.

Dogwood bark was used many years ago as an antiperiodic in *intermittent fever,* but it is only a feeble, astringent tonic. Formerly from one to two ounces of the powder were given in the interval between the paroxysms of intermittent fever.

Dose, of the fluidextract, from one-half to one drachm (1.8–3.75 cc.).

Off. Prep.—Fluidextractum Corni, *N. F.*

CORYDALIS. N. F.

CORYDALIS Corydal. [Turkey Corn, Squirrel Corn]

"The dried tubers of *Dicentra canadensis* (Goldie) Walp or of *Dicentra Cucullaria* (Linné) Bernh. (Fam. *Fumariaceæ*). Corydalis contains not more than 3 per cent. of foreign organic matter." *N. F.*

Dicentra canadensis and *D. Cucullaria* are delicate, low, perennial herbs indigenous to rich woodlands from Nova Scotia to Minnesota south to North Carolina, Kentucky and Missouri. The former is commonly known as *Turkey Corn* or *Squirrel Corn* while the latter is called *Dutchman's Breeches.* The aerial portions of both of these plants agree in possessing narrow-stalked, ternately-compound, dissected leaves and few-flowered racemes. The plants differ mainly in respect to their tubers and flowers. *Turkey corn* has scattered, pea-like tubers arranged on subterranean shoots, whereas the tubers of *Dutchman's Breeches* are somewhat scale-like and attached to the subterranean shoots in clusters of three. The flowers of *Turkey corn* are heart-shaped, greenish-white, tipped with rose, each showing 2 short, rounded spurs, whereas those of *Dutchman's Breeches* are irregularly heart-shaped, white, tipped with cream color, each possessing two more elongated and divergent spurs.

Description and Physical Properties.—"*Unground Corydalis.*—Tubers of *D. canadensis* spheroidal, frequently vertically depressed, one surface more or less concave, up to 15 mm. in diameter; usually single, rarely two or more in a cluster; externally, minutely pitted or nearly smooth, grayish brown, grayish black, or amber-colored and more or less translucent; one of the flattened surfaces with a triangular scar from detached roots, the other usually with remains of the slender rhizome; fracture, hard and horny, exhibiting a yellowish, waxy interior, or somewhat tough and granular, exhibiting a yellowish white interior. Tubers of *D. cucullaria* ovoid or triangular-ovoid, up to 12 mm. long; the larger distinctly concave on one surface, with a scar at the apex from the detached petiole, and usually attached to the short rootstock in clusters of three; the smaller grains usually separated from the rootstock, with an acute apex and a scar at the base; externally, yellowish, or grayish brown, usually translucent; fracture hard and horny, exhibiting a grayish, waxy interior, or granular and tough, exhibiting a whitish interior. Nearly odorless; taste slightly bitter.

"*Powdered Corydalis.*—Light yellow or yellowish gray; numerous oval, ovoid or oblong, simple starch grains, the broad end of the grain sometimes truncate, up to 0.060 mm. long and frequently with a cleft or horse-shoe-shaped fissure in the small end of the grain; occasionally in 2-compound grains, altered starch grains up to 0.090 long; numerous angular or rounded parenchyma cells isolated or in groups and containing more or less altered starch grains the outlines of which are indistinct; tracheæ few, with reticulate, simple pores, annular or spiral markings; fragments of epidermal cells with thin brownish walls; fibers very few or absent; few characteristic stone cells, often irregular in outline, mostly elongated, up to about 0.750 mm. long and 0.150 mm. wide, walls heavily lignified and about 0.020 mm. thick and porous, occurring isolated or in groups of from 2 to 4; very few rosette crystals of calcium oxalate, up to 0.020 mm. in diameter.

"An infusion prepared by placing 5 Gm. of powdered Corydalis in 100 cc. of hot distilled water, stirring occasionally during ten minutes and then filtering, is of a light amber color, and gives a precipitate with mercuric-potassium iodide T.S. and a dark blue color with iodine T.S." *N. F.*

As far as we know the constituents of this drug have never been determined. Several species of the closely allied genus *Corydalis* have, however, been carefully studied, especially the *C. cava* Schweig. and the *C. tuberosa.* The bulbs of these plants yield quite a variety of alkaloids which Gadamer (*A. Pharm.*, 1910, 1911, 1916) classifies into three groups as follows: 1. *Corydaline, dehydrocorydaline, corybulbine, iso-corybulbine,* and *corypalmine;* 2. *Corycavine, corycavamine, corycavidine;* 3. *Bulbocapnine, corytubine* and *corydine.* The alkaloid protopine is also found in several species. All of these alkaloids have narcotic actions but the first group are primary depressants of the spinal cord while the second and third excite before paralyzing the motor centers. (For further information concerning these substances see Henry, *Plant Alkaloids,* 1924.)

The tubers of bicuculla are asserted to be tonic, diuretic, and alterative, and are given in *syphilitic, scrofulous,* and *cutaneous affections,* They are used in the form of tincture or decoction. *Corydalin* or *corydalia,* of the eclectics, is an impure resinous mixture.

Dose, ten to thirty grains (0.6–2.0 Gm.).

Off. Prep.—Fluidextractum Corydalis, *N. F.;* Elixir Corydalis Compositum, *N. F.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

COTARNINÆ CHLORIDUM. U. S.

COTARNINE CHLORIDE Cotarn. Chlor. [Cotarninæ Hydrochloridum, U. S. P. IX]

"The chloride [$C_{12}H_{14}O_3NCl$] of an alkaloid prepared from narcotine." *U. S.*

Description and Physical Properties.—"A yellow, odorless, crystalline powder. It is deliquescent in moist air. Cotarnine Chloride is very soluble in water and in alcohol, the solutions being yellow.

"Dissolve about 0.5 Gm. of Cotarnine Chloride in 10 cc. of distilled water, and add 2 cc. of a 15 per cent. aqueous solution of sodium hydroxide: a milk-white precipitate is produced which dissolves on agitation, but is reprecipitated from the solution after standing for some time, leaving the supernatant liquor clear but faintly yellow. Silver nitrate T.S. added to an aqueous solution of Cotarnine Chloride produces a white precipitate insoluble in nitric acid. About 0.2 Gm. of Cotarnine Chloride dissolved in 10 cc. of distilled water yields a brown precipitate of cotarnine periodide on the addition of 10 cc. of tenth-normal iodine. When this precipitate is collected on a filter, and dried to constant weight over sulphuric acid, it melts between 142° and 144° C.

"An aqueous solution of Cotarnine Chloride (1 in 20) is neutral to litmus paper. Heat gradually 0.1 Gm. of Cotarnine Chloride over a Bunsen burner: it is decomposed, evolving characteristic, disagreeable vapors and yielding a reddish-brown liquid, which gradually changes to a hard, charred mass. The ash remaining on the incineration of this mass is negligible." *U. S.*

Cotarnine is an artificial alkaloid prepared by the oxidation of narcotine with nitric acid, *opianic acid* being obtained as a by-product. It has been synthesized by Salway (*Tr. Chem. Soc.,* 1910, xcvii) from myristicin.

Uses.—The fact that the only chemical difference between hydrastinine and cotarnine is that in the latter OCH_3 is substituted for one atom of hydrogen led Freund to suggest the substitution of cotarnine for hydrastinine. It has been physiologically studied by Falk (*Th. M.,* 1896, x), Kehrer (*Monat. für Geburts. und Gynakol.,* 1907, xxvi, p. 709), Laidlaw (*Bio-Chem. J.,* 1910, v, p. 243), and others. It differs in its action from hydrastinine, in that it has practically no influence upon the circulation, but resembles it in its depressant action upon the spinal cord, and in its stimulant effect upon the uterine muscle. Because of its stimulating action upon the uterine muscle, it has been found of service in various forms of uterine hemorrhage, such as *menorrhagia* and *metrorrhagia.* On false analogy some have jumped to the conclusion that it should be useful in other forms of *hemorrhage,* and it was at one time extensively employed in the treatment of various forms of internal bleeding, under the trade names of *Stypticin* and *Styptol,* the latter being *cotarnine phthalate.* Hanzlik, however, has shown (*J. P. Ex. T.,* 1918, x, and 1919, xii, 71) that whether applied locally or administered internally cotarnine tends to increase rather than diminish the rapidity of the bleeding.

A double salt of cotarnine hydrochloride and ferric chloride appears on the market under the trade name of *cotargit* and is alleged to contain still better styptic properties than cotarnine. It occurs as a ruby-red crystalline powder freely soluble in water.

The *dose* is ordinarily from three-fourths to one and one-half grains (0.05 to 0.10 Gm.) but in emergency as high as three or four grains (0.2–0.25 Gm.) may be given as a single dose.

COUMARINUM. N. F.

COUMARIN Coumar.

"The anhydride of ortho-oxycinnamic acid [$C_6H_4(CH)_2OCO$ (146.09)] occurring naturally in Tonka, Melilot and other plants, or prepared synthetically." *N. F.*

Coumarin is found widely distributed through the vegetable kingdom, notably in the tonka bean (see Part II), in several species of clover (see *Melilotus*), in several sweet-scented grasses, in the *Trilisa odoratissima,* commonly known as *vanilla leaf* and also in *Asperula odorata* and some species of orchids.

It may be extracted from the above plants by boiling with 80 per cent. alcohol; the resultant tincture is evaporated until faint turbidity, when four volumes of water are added, which precipitates both coumarin and fats. The solution is then heated and filtered hot, which causes the fat to remain on the filter and the coumarin passes through and crystallizes out of the solution on cooling. It is also prepared synthetically by boiling a mixture of salicylic aldehyde, acetic anhydride and anhydrous sodium acetate under a reflux condenser, distilling the oily liquid which separates and crystallizing the distillate. It is also produced by the action of ethyl acetoacetate or of malic acid upon phenol in the presence of sulphuric acid.

Description and Physical Properties.—"Coumarin occurs in colorless, prismatic crystals, having a characteristic, fragrant odor and a bitter, aromatic and burning taste. It is sparingly soluble in cold water, more readily soluble in hot water, freely soluble in alcohol, ether or chloroform; also soluble in fixed or volatile oils.

"When heated to between 67° and 68° C. it melts, and at about 100° C. it commences to sublime; at from 290° to 291° C. it boils without decomposition. Coumarin dissolves in solution of sodium or potassium hydroxide, producing a yellow color and forming sodium or potassium coumarate, from which carbon dioxide precipitates the Coumarin. Coumarin is precipitated in colorless needles on the addition of hydrochloric acid to its hot concentrated sodium or potassium hydroxide solution. A saturated aqueous solution of Coumarin forms a precipitate upon the addition of iodine T.S. The precipitate is at first brown and flocculent and afterwards clots on shaking, forming a dark green curdy mass and leaving the liquid clear (distinction from *vanillin*). Coumarin is not extracted from its solution in ether by ammonia water (distinction from *vanillin*). Warm 0.1 Gm. of Coumarin with 1 cc. of an alcoholic solution of sodium hydroxide (1 in 4), add a few drops of chloroform and again warm; the mixture does not possess the disagreeable odor of phenylisocyanide (*acetanilid*)." *N. F.*

Coumarin is free from medicinal properties, and is used only for its odorous qualities. It is especially valuable for covering the odor of iodoform and is also an ingredient in aromatized castor oil. It finds a prominent place in *imitation vanilla extracts* of commerce. Its adulteration with terpin hydrate has been reported by J. C. Umney who finds the melting point of the ether-soluble portion the best method of its detection.

Off. Prep.—Oleum Ricini Aromaticum, *N. F.*

CREOSOTI CARBONAS. U. S.

CREOSOTE CARBONATE Creosot. Carb.

"Creosote Carbonate is a mixture of the carbonates of various constituents of creosote, chiefly guaiacol and creosol." *U. S.*

Creosote carbonate is known also by the trade names of *creosotal* and *creosotal-Heyden;* it is made by treating a solution of creosote and sodium hydroxide with carbonyl chloride.

Description and Physical Properties.—"A clear, colorless or yellowish, viscid liquid. It is odorless and tasteless, or has a slight odor and taste of creosote. On prolonged exposure to a low temperature, crystals of guaiacol carbonate may separate, which redissolve on warming. Creosote Carbonate is insoluble in water, but is freely soluble in alcohol. It is soluble in petroleum benzin and in fixed oils, and is miscible with chloroform and with benzene. Heat about 0.5 cc. of Creosote Carbonate for a few minutes with 10 cc. of alcoholic potassium hydroxide T.S., and cool the mixture: a crystalline precipitate forms, which effervesces with acids.

"Specific gravity: not below 1.145 at 25° C. Ash: not more than 0.1 per cent. An alcoholic solution of Creosote Carbonate (1 in 5) is neutral to moistened litmus paper, and acquires only a yellow color on the addition of a drop of ferric chloride T.S. (*free creosote*). Heat 25 cc. of Creosote Carbonate on a water bath for half an hour with a solution of 15 Gm. of potassium hydroxide in 100 cc. of alcohol, add about 50 cc. of water, and evaporate the alcohol. Treat the residue with an excess of hydrochloric acid, and allow the liquid to separate into two layers. Separate the creosote layer, wash it by shaking at first with 15 cc. of a 20 per cent. aqueous solution of sodium chloride, then with 10 cc. of water, and distil: eighty-five per cent. of the creosote thus obtained, allowance being made for adhering moisture, distils between 200° and 220° C., when determined by method II, page 433. The distillate, after the separation of adhering water, does not respond to the test for *hydrocarbons and "coal-tar creosote"* under *Creosotum." U. S.*

Uses.—Creosote carbonate has been used in medicine with the idea that it would be decomposed by the acid secretions of the stomach and exercise the characteristic beneficial effect of creosote, especially in *chronic bronchitis* and *tuberculosis.* The advantage of this preparation is that it is comparatively free from odor or taste and that it is much less irritant to the stomach. On the other hand, the *a priori* reasoning that it would be decomposed by the hydrochloric acid in the stomach is based upon false assumption. There is no chemical reason to suppose that this compound would be decomposed by the fluids of the digestive tract and we know of no convincing evidence that it is decomposed anywhere in the alimentary canal or that it liberates its creosote in the body. Although it is enormously prescribed, the question of its therapeutic value seems open to serious doubt.

Dose, from five to thirty minims (0.3–1.8 cc.) preferably in emulsion or capsules.

CREOSOTUM. U. S., Br.

CREOSOTE Creosot. [Creasote]

"A mixture of phenols, principally guaiacol [$C_6H_4(OH.OCH_3)1:2$] and creosol [$C_6H_3(CH_3)OH.OCH_3\ 1:2:3$] obtained from wood tar." *U. S.* "Creosote is a mixture of phenols which may be obtained by the distillation of beech tar, and consists chiefly of guaiacol and creosol." *Br.*

Creasotum, *Br.* (1885); Créosote Officinale, *Fr. Cod.;* Kreosotum, *P. G.;* Kreosot, Buchenholztheerkreosot, *G.;* Creosoto, *It.;* Creosota, *Sp.*

The destructive distillation of wood yields products analogous to one fraction of the coal tar, obtained by the destructive distillation of bituminous coal. This fraction is the heavy oil of coal tar, which comes over between 165° C. and 200° C.; it is often called *"coal tar creosote,"* and contains a group of phenols, including carbolic acid. Wood tar is a complex mixture of phenoloid bodies with acetic acid, varying considerably in its composition according to the species of wood from which it is made (see *Pix Pini*). The tars from the hard woods yields larger proportions of creosote. This is a mixture of methyl ethers of pyrocatechin and its homologues. It contains from 60 to 90 per cent. of guaiacol with *creosol* and small amounts of *phlorol* and methyl-creosol.

Preparation.—Creosote is obtained either from wood tar or from crude pyroligneous acid. When wood tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creosote, is separated, and saturated with sodium carbonate to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, after having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed until it is free from acidity, and then distilled with a fresh portion of weak phosphoric acid, care being taken to cohobate from time to time. The oily liquid thus rectified is colorless, and contains much creosote, but also a portion of light oil distillate. To separate the latter the liquid is mixed with a solution of sodium hydroxide of the density 1.12, which dissolves the creosote, but not the light oil. The oil, which floats from its levity, is then separated, and the alkaline solution of the creosote is exposed to the air, until it becomes brown in consequence of the decomposition of a foreign matter, and is then saturated with sulphuric acid. This sets free the creosote, which is decanted and again distilled. The treatment by solution of soda, sulphuric acid, etc., is to be repeated until the creosote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of soda, and distilled again, and finally redistilled for the last time, rejecting the first portion which comes over, on account of its containing much water, and collecting the next portion; care being taken not to push the distillation too far. The product collected is creosote.

When creosote is extracted from pyroligneous acid, the first step is to dissolve sodium sulphate in the acid to saturation. The oil which separates and floats above is decanted, and, having been allowed to remain at rest for a few days, is saturated with potassium carbonate with the assistance of heat, and distilled with water. The oily liquid obtained is of a pale yellow color, and is to be treated as above detailed, in relation to the treatment of the corresponding oil obtained from wood tar.

Creosote, when pure, is a colorless oleaginous liquid, but as met with in commerce, it has frequently a brownish tinge. Mixed with water, it forms two layers, one consisting of one part of creosote and about eighty of water, the other, of one part of water and ten of creosote. It dissolves a large proportion of iodine and phosphorus, and a considerable amount of sulphur, especially when assisted by heat. Allen states that in Rhenish creosote guaiacol predominates, while a sample of Morson's creosote from "Stockholm tar," examined by him, boiled at about 217° C., and consisted chiefly of creosol.

Description and Physical Properties.—"An almost colorless or yellowish, highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste. It does not readily become brown on exposure to light. Creosote is inflammable, burning with a luminous, smoky flame. Creosote is slightly soluble in water, but is miscible with alcohol, ether, and with fixed or volatile oils.

"Add 1 drop of ferric chloride T.S. to 10 cc. of a saturated aqueous solution of Creosote: a violet-blue color, which is very transient, develops. The liquid becomes cloudy almost instantly, the color changing rapidly from grayish-green to muddy brown, with the formation, finally, of a brown precipitate.

"Specific gravity: not below 1.076 at 25° C. It begins to distil at about 200° C., and not less than 90 per cent., by volume, distils between 200° and 220° C., when determined by method II, page 1536. Creosote is neutral or faintly acid to moistened litmus paper. Mix equal volumes of Creosote and collodion in a dry test tube: no permanent coagulum is produced (*phenol* and so-called *"coal-tar creosote"*). Mix 4 cc. of Creosate and 4 cc. of glycerin, add 1 cc. of water, shake the mixture gently, and allow it to stand: a creosote layer separates equal to or greater in volume than the Creosote taken (so-called *"coal-tar creosote"*). A 2 cc. portion of Creosote requires not less than 10 cc. and not more than 18 cc. of normal sodium hydroxide to produce a clear liquid. This liquid remains unclouded on diluting with 50 cc. of distilled water (*hydrocarbons and bases*). Shake gently 1 cc. of Creosote with 2 cc. of petroleum benzin and 2 cc. of freshly prepared barium hydroxide T.S. until a uniform mixture results: upon complete separation three distinct layers are visible, the upper layer being neither blue nor muddy (*cærulignol*).

"Preserve in tightly-stoppered, dark amber-colored bottles." *U. S.*

The British Pharm. describes creosote as "a colorless or pale yellow, highly refractive liquid, neutral or faintly acid to *litmus*. Freely soluble in *alcohol* (90 per cent.), in *ether*, in *chloroform*, and in *glacial acetic acid*. Specific gravity not below 1.080. Commences to boil below 200° C. Not less than 75 per cent. distils between 200°

and 220° C. A solution (1 in 100) in *alcohol* (90 per cent.) produces with a drop of *T. Sol. of ferric chloride* a green coloration rapidly changing to reddish brown. Dropped on white filter paper and exposed to a temperature of 100° C., it leaves no translucent stain (absence of less volatile liquids)." *Br.*

Creosote dissolves a number of metallic salts and reduces some of them to the metallic state, as, for example, silver nitrate and acetate. *Froehde's reagent* (a solution of 0.1 Gm. of sodium molybdate in 100 cc. of concentrated sulphuric acid) is recommended by E. W. Davy as a distinguishing test for phenol. A drop or two of the doubtful liquid is to be agitated with two fluidrachms of distilled water, the whole filtered, and a drop or two of the test solution added. Pure creosote gives a brown or reddish-brown reaction on standing or slight warming, passing to a light yellowish-brown; with phenol, the brown passing to a maroon soon develops a more or less intense purple. The name creosote refers to its antiseptic properties, being derived from χρέας, *flesh,* and σώζω, *I preserve.*

Impurities and Adulterations.—Creosote is sometimes adulterated with rectified oil of tar and the fixed and volatile oils. All these substances are detected by strong acetic acid, which dissolves the creosote, and leaves them behind, floating above the creosote solution. Creosote from beechwood tar, however, is only partially dissolved by hot acetic acid of ordinary strength. Fixed oils are also discovered by a stain on paper not discharged by heat. Any trace of the matter which produces the brownish tinge is detected by the liquid becoming discolored by exposure to sunshine. Commercial creosote sometimes contains phenol and cresol, from coal tar; and, indeed, much of what has been sold for creosote was nothing more than impure phenol. (See *Phenol.*) It has been already stated that phenol strongly resembles creosote; but the effects of the two on the system are very different. The presence of phenol is excluded by the official tests. The large doses in which creosote is now sometimes given makes the sale of the so-called "coal tar creosote" dangerous, for there would be a strong probability that a patient might be given a large dose of phenol with disastrous effects; all pharmaceutical manufacturers have ceased to label or market "coal tar creosote."

Uses.—Although the constitution of even genuine beechwood creosote varies very greatly in the proportion of guaiacol and creosol, the physiological and therapeutic action of its various constituents is so closely allied as to make variability in the proportion of these constituents of little importance.

The physiological effects produced by creosote have not been closely studied, but it would appear in many of its properties to resemble phenol. It is, however, much less poisonous and doses as high as thirty to sixty minims have been administered three times a day without harmful results. Freudenthal (*N. Y. M. R.,* April, 1892) reports a case of a woman who took six hundred drops of creosote in a very short time, the ingestion being followed almost immediately by unconsciousness with intense trismus, contracted immobile pupil, and general cyanosis, but recovery was made practically without administration of remedies; subsequently this same patient by graduating the dose was able to take five hundred drops daily without ill effect. Thorling (*Upsala Lakaref. Förh.,* Sept. 1, 1921) has reported a case of fatal poisoning in an infant of two months from what was estimated to be 0.6 cc. of creosote. Icterus and evidence of destruction of the blood cells were prominent symptoms.

Creosote is absorbed readily from the intestinal tract and its elimination is fairly rapid. It escapes chiefly through the kidneys in combination with sulphuric and glycuronic acids, but appears also to be in part eliminated by the lungs. Like phenol, it is, when locally applied, a paralyzant to the sensory nerves. Creosote is distinctly superior to phenol in its antibacterial properties, especially in dilute solutions. According to Guttmann (*Z. K. M.,* 1887, xiii) one part of creosote to three thousand completely inhibits the growth of bacteria.

Creosote was originally introduced in the treatment of *phthisis* with the idea that it would exercise an antiseptic action in the lungs. It is, however, extremely questionable whether the drug can reach the pulmonic tissue in sufficient concentration to have any direct antibacterial properties. Its beneficial influence in this disease can be ascribed to its stimulating effect upon the bronchial mucous membrane. For this action it is also a very valuable drug in the treatment of all types of *chronic bronchitis,* especially when there is over-secretion. In tubercular conditions it is generally necessary to give the drug in large doses. The secret of doing this successfully is to see that it is well diluted before ingestion. When being used freely it should never be given in the form of capsules but dissolved in either water or milk. A good rule is that the patient should take at least one-half an ounce of fluid for every drop of creosote; thus if ten minims were to be administered it would require five ounces of water. Perom has recommended the hypodermic administration in *phthisis.* For this purpose he uses a ten per cent. solution in oil of sweet almonds, two injections of eighty minims being given daily. Dor employed intratracheal injections of five per cent. solution in sterile olive oil.

Creosote is also a valuable gastro-intestinal antiseptic in the treatment of *fermentative gastritis* and *enteritis.* It is of service in *nausea* and *vomiting* for its local anesthetic action upon the gastric mucosa. Externally it has been used as a surgical disinfectant, but because of its stronger odor and greater cost is inferior to phenol, but when there is foul discharge, as in fetid *leukorrhea, otorrhea, empyema* or *gan-*

grene, is by many preferred. It is also useful in various *skin diseases,* both for its local anesthetic and antibacterial properties and has been recommended in *chilblains.* In capillary *hemorrhages* it has some power as a hemostatic but is not capable of arresting bleeding from large vessels. For this effect it has been used locally in the milder types of *uterine hemorrhage* and to stop the bleeding from *leech bites.* As a local application it may be employed in strengths of from one to ten per cent., according to the purpose for which it is used. On account of its local anesthetic and antiseptic influence, it is much employed by dentists for the obtunding of sensitive dentine and as an ingredient of pastes for the destruction of nerves. One or two drops of the pure substance must be carefully introduced into the hollow of the tooth on a little cotton, avoiding contact with the tongue or cheek. To render it effectual, the hollow of the tooth must be well cleansed before it is applied.

In an overdose creosote acts as a poison, producing giddiness, obscurity of vision, depressed action of the heart, convulsions, and coma. Medicinal treatment consists in evacuation of the poisons and administration of ammonia and other stimulants.

Under the name of *Vapor Creasoti* (*Inhalation of Creasote*), the British Pharmacopœia (1885) directed a preparation consisting of 12 minims of creosote and 8 fluidounces of boiling water, which were directed to be mixed in an inhaling apparatus, so arranged that the air should be made to pass through the solution, and then inhaled. It may be used in chronic inflammation of the air passages.

Mistura Creosoti, Br. Pharm., 1898, is no longer official, it was made by shaking 16 minims each of creosote and spirit of juniper with 1 fluidounce of syrup and enough distilled water to make 16 fluidounces of the mixture.

Dose, of creosote, five to ten minims (0.3–0.6 cc.), which may be gradually increased.

Off. Prep.—Unguentum Creosoti, *Br.;* Mulla Creosoti Salicylata, *N. F.;* Elixir Terpini Hydratis et Creosoti Compositum, *N. F.*

CRESOL. U. S., Br.

CRESOL

"A mixture of isomeric cresols [$C_6H_4.CH_3.OH$] obtained from coal tar." *U. S.* "Cresol is a mixture of isomers of the formula C_7H_7OH, obtained from coal tar. Should be preserved in stoppered amber-colored bottles." *Br.*

Cresolum, Cresolum Crudum; Cresylic Acid, Tricresol, Methylphenol, Oxytoluene; Crésylol Officinale, *Fr. Cod.;* Enterol, Trikresol, Kresol, *G.*

Preparation.—Cresol is prepared from coal tar by collecting the distillates coming over between 140° C. and 220° C., and purifying these by treatment with solution of sodium hydroxide and hydrochloric acid.

There are three isomeric cresols: *orthocresol,* melting at 31° C. and boiling at 188° C.; *metacresol,* a liquid boiling at 201° C., but not solidifying even at –80° C.; and *paracresol,* forming colorless prisms, melting at 36° C. and boiling at 198° C. These cresols are all obtainable by fractional distillation from that portion of coal tar boiling between 190° and 210° C. The official drug is a mixture of all three.

Description and Physical Properties.—"A colorless, or yellowish to brown-yellow, or a pinkish, highly refractive liquid, becoming darker with age and on exposure to light. It has a phenol-like, sometimes empyreumatic odor. One cc. of Cresol is soluble in about 50 cc. of water, usually forming a cloudy solution. It is miscible with alcohol, ether, benzene, petroleum benzin, and with glycerin, and is dissolved by solutions of the fixed alkali hydroxides.

"Specific gravity: 1.030 to 1.038 at 25° C. Not less than 90 per cent. by volume of Cresol distils between 195° and 205° C., when determined by method II, page 433. A saturated aqueous solution of Cresol is neutral or slightly acid to litmus paper, and becomes bluish-violet on the addition of ferric chloride T.S. A solution of 1 cc. of Cresol in 60 cc. of distilled water shows no greater turbidity than that produced in 58 cc. of distilled water by the addition of 1.5 cc. of fiftieth-normal sulphuric acid and 1 cc. of barium chloride T.S., comparison being made after the control mixture has been well shaken and allowed to stand for five minutes (*hydrocarbons*).

"Preserve in well-closed containers, protected from light." *U. S.*

It is stated that much of the commercial cresol does not comply with the U. S. P. requirements for specific gravity and boiling point (Ewe, *Proc. Penna. Pharm. Assoc.,* 1915, p. 1.6.)

"A straw-colored liquid, becoming brown on keeping or on exposure to light. Soluble in 50 parts of *water,* the solution being neutral to *litmus;* freely soluble in alcohol (90 per cent.), in *ether,* in *chloroform,* in *glycerin,* and in the fixed and volatile oils. Specific gravity 1.040 to 1.050. When 0.5 millilitre is shaken with 300 millilitres of *water* and filtered, the filtrate gives a transient bluish color on the addition of *T. Sol. of ferric chloride.* Not less than 90 per cent. distils between 195° and 205° C. 10 millilitres shaken with 10 millilitres of an aqueous solution (1 in 10) of *sodium hydroxide* form an almost clear liquid, from which no appreciable oily layer separates on standing for twenty-four hours (limit of hydrocarbon oils). 5 millilitres mixed with 5 millilitres of *glycerin* form a clear solution from which, on the addition of 5 millilitres of *water,* the cresol completely separates (absence of phenol)." *Br.*

Uses.—Cresol is used in medicine solely for its disinfectant properties. It far surpasses phenol in power, both as a germicide and antiseptic. Reed (*Trans. of the Association of Military Surgeons,* U. S., 1894, iv) finds that a one-half per cent. solution of cresol is sufficient to destroy the staphylococcus in less than twenty minutes; a one per cent. solution killed in thirty seconds and is equivalent to a four or five per cent. solution of phenol. Ditthorn (*J. Soc. Chem. Ind.*, 1920, xxxix, 799A) finds that of the isomers meta-cresol is the most actively germicidal and that the orthocresol is slightly weaker than the para. Because of the sparing solubility of cresol in water it is generally employed in the form of a soapy solution or emulsion (see *Liquor Cresolis Compositus*). This solution retains the germicidal properties of the cresol, thus Fox (*Report of the Commissioner of Health of the State of Pennsylvania,* 1907, p. 123) finds that one per cent. of the official compound solution of cresol kills non-sporulating bacteria after two minutes' exposure and is superior to a one per cent. solution of phenol. McClintock (*U. S. Hygienic Laboratory Bulletin,* No. 82, April, 1912) gives the phenol coefficient of compound solution of cresol: Without organic matter 3.0, with organic matter 1.87. (For a list of some of the proprietary preparations of cresol, see Part II.) There is probably some difference in the germicidal powers of the various cresols so that the mixture which is known officially as cresol varies more or less in activity. According to Sage (*P. J.*, 1908, lxxx, p. 730) the compound solution of cresol of the British Pharmacopœia has a phenol coefficient varying from 1.25 to 3.75 according to the value of the cresylic acid from which it is made. Other authorities, however, do not find so great a variation.

The statement has been made that cresol is practically non-poisonous, but such is certainly incorrect. It is perhaps somewhat less toxic than phenol, but the difference is not very great, and there have been a number of fatal cases of cresol poisoning reported, as well from its use as a douche as from swallowing. The symptoms have been nausea and vomiting, general depression with a tendency towards stupor, gradually developing into coma, smoky albuminous urine, fall of bodily temperature, and collapse. Friedlander (*Th. M.*, 1907) recommends as antidotes large quantities of oil or the white of egg, which he believes act by preventing absorption; milk and watery fluids are to be avoided.

Cresol is used chiefly as a surgical disinfectant, both for the purpose of sterilizing instruments and as a wound dressing. For the former three to five per cent. of the compound solution should be employed, while for application to wounds one per cent. of the compound solution (representing one-half per cent. of cresol) is generally recommended. Cresol is also employed to a limited extent as a gastro-intestinal antiseptic in various types of *enteritis* and *gastritis.* For this purpose one or two minims (0.06–0.12 cc.) of the cresol, well diluted, may be given.

Vanderkleed and Ewe report that cresol acts as an alkaloidal precipitant under certain conditions and advise against the use of cresol as a preservative in ampules of alkaloidal solution.

Dose, from one to three minims (0.06–0.2 cc.).

Off. Prep.—Liquor Cresolis Compositus, *U. S.* (*Br.*).

CRETA PRÆPARATA. U. S., Br.

PREPARED CHALK Cret. Præp. [Drop Chalk]

"Prepared chalk is a native form of calcium carbonate freed from most of its impurities by elutriation and containing, when dried to constant weight at 200° C., not less than 97 per cent. of $CaCO_3$." *U. S.* "Prepared Chalk is native calcium carbonate, freed from most of its impurities by elutriation." *Br.*

Creta Lævigata; Craie Lavée, Craie préparée, *Fr.;* Präparirte Kreide, Schlämmkreide, *G.;* Creta preparada, *Sp.*

Preparation.—Calcium carbonate, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of shells, and a small proportion of the bones of the higher orders of animals. It is present in small quantity in most natural waters, being held in solution as the bicarbonate, $Ca(HCO_3)_2$, by the carbon dioxide which they contain. In the waters of limestone districts it is a very common impregnation, and causes purging in those not accustomed to its use. In all such cases, boiling the water, by expelling the carbon dioxide, causes the carbonate to be deposited. It has been shown, however, that calcium carbonate is itself in a slight degree soluble in water; so that a small proportion remains in limestone water which has been long exposed to boiling.

Chalk occurs abundantly in the south of England and the north of France. It exists in massive beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals. According to F. V. Hayden, chalk beds identical with those of Europe extend for 400 miles along the Missouri River in Dakota. Chalk is an insipid, inodorous, insoluble, opaque, soft solid, generally white, but grayish-white when impure. It is rough to the touch, easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a white trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2.3 to 2.6. It is never a perfectly pure calcium carbonate, but contains besides gritty siliceous particles, small portions of alumina and ferric oxide. If pure, it is entirely soluble in hydrochloric acid, but usually a little silica is left. If this solution be not precipitated by ammonia, it is free from alumina and iron. Chalk, on account of the gritty particles which it contains, is unfit for medicinal use until it has been prepared by the following process: It is first reduced to a very fine powder. This powder is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. This process of purification is called elutriation or water sifting. The soft mass which remains after the decanting of the clear liquor is made to fall upon an absorbent surface in small portions, which when dried have a conical shape. This part of the operation is known as trochiscation.

The by-product of the manufacture of prepared chalk, which contains earthy impurities, is commonly sold as *whiting*.

Description and Physical Properties.—"A white to grayish-white, very fine, amorphous powder, often formed into 'conical drops.' It is odorless and tasteless, and is stable in the air. When heated to about 825° C., Prepared Chalk gradually loses carbon dioxide and is converted into calcium oxide. Dissolve about 0.1 Gm. of Prepared Chalk in 5 cc. of diluted acetic acid, and filter the solution: this solution responds to the reactions for calcium.

"Prepared Chalk is practically insoluble in water and is insoluble in alcohol. It is decomposed and dissolved by diluted acetic, hydrochloric, or nitric acid, with copious effervescence. When a weighed amount of Prepared Chalk is dissolved in diluted hydrochloric acid and the insoluble residue collected and ignited, it yields not more than 2 per cent. of the amount of Prepared Chalk taken.

"**Assay.**—Proceed as directed under *Calcii Carbonas Præcipitatus.*" *U. S.*

"White friable masses or a white powder. Yields the *reactions* characteristic of calcium and of carbonates. Yields not more than the slightest characteristic *reactions* for iron, aluminium, magnesium, phosphates, sulphates, or silica. *Arsenic limit* 5 parts per million. A solution of Prepared Chalk in *diluted acetic acid* yields no precipitate with *solution of potassium chromate* (absence of barium carbonate)." *Br.*

Uses.—Prepared chalk is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to *diarrhea* accompanied with acidity. It is also used in *acidity of stomach,* when a laxative effect is to be avoided, and it is one of the best antidotes for oxalic acid. It has been employed as an application to *burns* and *ulcers,* which it moderately stimulates, while it absorbs the ichorous discharge and thus prevents it from irritating the diseased surface or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ.*) Prepared chalk is better fitted for chalk mixture than the precipitated calcium carbonate, in consequence of its more impalpable character and greater powers of adhesion.

Dose, from ten to forty grains (0.65–2.6 Gm.).

CROCUS. N. F.

SAFFRON Croc.

"Saffron is the stigma of *Crocus sativus* Linné (Fam. *Iridaceæ*). Saffron contains not more than 10 per cent. of yellow styles, or other foreign organic matter and yields not more than 7.5 per cent. of total ash." *N. F.*

Autumnal Crocus; Stigmata Croci; Spanish Saffron; Safran, *Fr. Cod.;* Crocus, *P. G.;* Safran, *G.;* Zafferano, *It.;* Azafran, *Sp.*

Crocus sativus is a perennial plant, with a rounded and depressed bulb or corm, from which the flower rises a little above the ground, upon a long, slender, white, and succulent stem. The flower is large, of a beautiful lilac or bluish-purple color, and appears in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface, with a white longitudinal furrow in the center, paler underneath, with a prominent flattened midrib; they are enclosed at their base—together with the tube of the corolla—in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between the two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange color, highly odorous, rolled in at the edges, and notched at the summit. The stigmas of the *Crocus orientalis* are used in the East.

C. sativus is believed to be a native of Greece and Asia Minor, where it has been cultivated from the earliest ages. There are three main varieties of it, the French, the Grecian, and the Chinese. The first of these is superior in color and flavor, the second in the amount of yield, while the third is said to unite these qualities. Saffron is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. Large quantities of saffron are raised in Egypt and Persia. We cultivate the plant in this country chiefly as a garden flower, although some of the drug of very fine quality has been produced in Pennsylvania; the high cost of labor in America will probably prevent the possibility of its coming into commerce. Wild saffron is found growing in uncultivated fields in Southern Russia; Tichomirow believes that these are varieties of *C. sativus* and *C. speciosus* Marsh. Biebr., var. *β-Pallassii* (*C. Palassii* Marsh. Biebr.). He further states that wild saffron from these sources is in no way inferior to the cultivated. (*A. Pharm.,* 1903, 656.)

For an account of the cultivation in England, see *P. J.*, June, 1887. The Spanish saffron is generally considered the best in the United States.

Saffron has a peculiar, sweetish, aromatic odor, a warm, pungent, bitter taste, and a rich deep orange color, which it imparts to the saliva when chewed.

Description and Physical Properties.—"*Unground Saffron.*—Stigmas 3, united or separate, attached to the apex of the style; usually about 25 mm. long, cornucopia-shaped, of a dark, rich red color, the margin dentate or fimbriate; styles about 10 mm. long, more or less cylindrical, solid, yellowish. Odor strong, peculiarly aromatic; taste bitterish, aromatic. When chewed it colors the saliva orange-yellow.

"*Structure.*—Upper end of the stigma with numerous cylindrical papillæ about 0.150 mm. long, among which occur a few spherical pollen grains, the latter being nearly smooth, and from 0.040 to 0.120 mm. in diameter; occasionally some of the pollen grains germinated, and with pollen tubes.

"When placed in sulphuric acid, the stigmas are immediately colored blue, gradually changing to violet, and finally become a deep wine-red color. Add 0.01 Gm. of finely powdered Saffron to 100 cc. of cold water, allow it to macerate for several hours and filter; on adding 10 cc. of this filtrate to 100 cc. of water, it gives a distinctly yellow-colored solution. Macerate 0.01 Gm. of Saffron in 5 cc. of methyl alcohol; a deep orange color is imparted to the liquid. Macerate 0.01 Gm. of Saffron in 5 cc. of acetone, alcohol, or dehydrated alcohol; a distinct, lemon-yellow color is produced. With corresponding quantities of Saffron and ether a very light lemon-yellow color is produced. With corresponding quantities of Saffron and chloroform a very slight yellow tinge is imparted; and with corresponding portions of Saffron and xylene, benzene, carbon disulphide, or carbon tetrachloride, the solvents remain colorless. When Saffron is pressed between filter paper, the paper does not display transparent spots due to the absorption of oil. Saffron loses not more than 12 per cent. of its weight when dried at 100° C.

"Preserve it in tightly closed containers, protected from light." *N. F.*

Constituents.—Analyzed by Vogel and Bouillon-Lagrange, saffron afforded 65 per cent. of a peculiar extractive matter, which they named *polychroïte,* but later researches have shown that it is a mixture of the glucoside *crocin,* sugar, and essential oil. (Planchon, *Drogues Simples,* vol. i, 210.) Kayser obtained (*B. Chem. G.*, 1884, 2228) pure *crocin,* having the formula $C_{44}H_{70}O_{28}$, as a yellow powder, easily soluble in water and diluted alcohol, only slightly soluble in absolute alcohol, and giving with concentrated sulphuric acid a deep blue color, which turns violet, then cherry-red, and finally brown. It is easily hydrolyzed into *crocetin* and a dextro-rotatory sugar which Kayser calls *crocose.* The crocetin is a red powder, not soluble in water, but easily soluble in alcohol and ether. Its solution in alkalies shows an orange-yellow color, from which solution acids separate it again in orange-colored flecks. Its formula is $C_{34}H_{46}O_9$, or, according to Schmuck and Marchlewski, $C_{15}H_{20}O_4$. Kayser also found a colorless bitter principle, to which he gave the name *picro-crocin* or *saffron bitter,* and the formula $C_{38}H_{66}O_{17}$, which is also of glucoside character. Winterstein and Teleczky (*Helv. Chim. Acta.*, 1922, v, 376) isolated a colorless crystalline ketonic compound having the composition $C_{10}H_{14}O$, which they also call picro-crocin. They believe this principle to have accompanied and contaminated the crocin of previous investigators. It belongs to the terpene series and is related to carvone. According to T. Munesada (*J. Pharm. Soc. Jap.*, 1922, 486, p. 661) *Gardenia grandiflora* also contains crocetin which he gives the formula $C_{10}H_{13}O.OH$ and states that it is a derivative of saffron. Saffron contains, according to Henry, about 10 per cent. of essential oil. This has the formula $C_{10}H_{14}O$, boils at 208° to 210° C., is yellow, of a hot, acrid, bitterish taste, and heavier than water.

Adulterations.—The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Oil or glycerin is also added for the same purpose, or to improve the appearance. In some specimens the dyed corolla of the crocus with the attached stamens is abundant. Sometimes the flowers of other plants, particularly *Carthamus tinctorius,* or *safflower, Calendula officinalis,* or marigold, and *arnica* are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into warm water, to expand them. A ready method of detecting Carthamus in powdered saffron suggested by Vicari is based on the fact that saffron gives a blue coloration with a reagent made by mixing 60 cc. of concentrated sulphuric acid with 40 cc. of a 10 per cent. solution of sodium phosphomolybdate. The powder is spread over a glass slide and a drop of the reagent added and well mixed. When examined by the microscope the particles of carthamus stand out because of their reddish color, in contrast with the blue of the true crocus. According to Heim, *Crocosma aurea* Pl., which is cultivated in Southern Africa as a dye-stuff, affords an excellent substitute for saffron, the dried petals giving, when treated with water, a brilliant yellow solution. The partly dry aqueous extract gives with sulphuric acid a blue coloration, passing to violet, similar to that obtained from saffron. Other adulterations are the fibers of dried beef, the stamens of the crocus, distinguishable by their yellow color, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances, easily detected upon close examination. The ligulate florets of *Calendula officinalis* have been factitiously colored and employed to adulterate Crocus. This article, known as *Feminell,* has a carmine-red color and when mounted in chloral solution and examined microscopically shows elongated epidermal cells bearing near the tube of the corolla large multicellular hairs, yellowish oil globules in the parenchyma and spiny pollen grains.

An adulteration which has been largely practised appears to consist of yellow-colored chalk or barium sulphate, made into a thin paste, probably with honey, and attached to the stigmas, sometimes isolated, sometimes in groups of five or six, enveloping them almost completely. If this saffron be kept in a dry place, and often handled, the paste becomes partly broken up, and the colored powder spreads itself in the mass and the envelope. The chalk can at once be detected by shaking the suspected saffron with water, and treating the precipitated powder with hydrochloric acid, when effervescence will occur. A less than the ordinary brightness of color in the saffron should lead to suspicion of this adulteration. Much can be told as to the purity of saffron by agitating the suspected flowers in distilled water; if the drug be pure the liquid will remain clear, slowly assuming a fine pure yellow tint; the saffron also will retain its red color for hours. Another excellent plan is to scatter a pinch of the flowers upon the surface of warm water, when the stigmas should spread out and display their proper form. Minute fragments of red saunders, which are occasionally added to saffron, may be separated by agitating with water. Adulterations of crocus may sometimes be detected by remembering that the pollen grains of *Crocus sativus* are spheroidal, nearly smooth, and from 0.040 to 0.075 mm. in diameter. In various European markets there has been offered a saffron largely adulterated with borates, chlorides, and other salts of sodium and potassium, and yet retaining the physical properties of saffron of high character. These and other adulterations with inorganic salts can be detected by the amount of ash left on burning, genuine saffron leaving from five to seven per cent. The borated saffron also yielded immediately to water an orange-yellow color. Further, some of it at least was hygroscopic, so that when rubbed up between the fingers into a ball it retained that form instead of being elastic as is true saffron.

A more recent adulterant for Crocus consisted of the florets of a species of *Onopordon* artificially dyed with Tartrazine and commercial Ponceau 2 R, and weighted with borax, glycerine and saltpeter. This adulterant may be detected by the presence of tubular florets, the corollas of which bear club-shaped multicellular, glandular hairs, by the pollen grains with a peculiarly thickened triangular coat and by the narrow extension of the stamens above the anthers. The artificial dyes may be determined by the pink to red color produced when the material is placed in an organic solvent.

A product called *Cape Saffron* formerly attracted some attention but is now rarely met with. It consists of the flowers of a scrophulariaceous shrub, *Lyperia atropurpurea* Benth., which grows in South Africa.

Uses.—Saffron was extensively used by the ancients and by medieval physicians, as a nerve sedative and emmenagogue, and is still employed to some extent in Europe; but in Great Britain and the United States it has fallen into well deserved and almost complete desuetude. In domestic practice saffron tea is occasionally used in *exanthematous diseases,* to promote the eruption. At present it is chiefly used to impart color and flavor. Saffron should be preserved in tightly-closed containers protected from light.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

CUBEBA. U. S. (Br.)

CUBEB Cubeb. [Cubebs]

"Cubeb is the dried, nearly full-grown, unripe fruit of *Piper Cubeba* Linné filius (Fam. *Piperaceæ*). Cubeb contains not more than 5 per cent. of its shriveled immature fruits or stems, or not more than 2 per cent. of other foreign organic matter, and yields not less than 10 per cent. of volatile ether-soluble extractive." *U. S.* "Cubebs are the dried full-grown unripe fruits of Piper Cubeba, *Linn. fil.*" *Br.*

Cubebæ Fructus, *Br.;* Fructus (s. Baccæ) Cubebæ, Piper Caudatum; Tailed Pepper; Cubèbe, *Fr.Cod.;* Poivre à Queue, *Fr.;* Cubebæ, *P. G.;* Kubeben, *G.;* Pepe Cubebe, *It.;* Semilla de Cubeba, *Sp.;* Kebabeh, *Ar.*

Piper Cubeba is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate-oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nerved, coriaceous, and very smooth. The flowers are diœcious and in spikes, with peduncles about as long as the petioles. The fruit is a globose, pedicelled drupe. This species of Piper is a native of Java, Borneo and Sumatra. It is extensively grown in the coffee plantations, supported by the trees which are used for shade, and has been introduced into Ceylon and the West Indies. The fruits are found in numbers of 50 or more on each spike. They are collected while still green, though full grown, and dried in the sun. They are then sent to Batavia or Singapore for export. The commercial supplies coming into the United States are shipped either direct from Singapore or through London and Amsterdam. Our knowledge of the false cubeb of commerce up to 1894 was epitomized in the 17th edition of the *U. S. D.*, p. 457. To this account the reader is referred for historical details. (See also *U. S. D*,. 19th ed., p. 410.)

Description and Physical Properties.—"*Unground Cubeb.*—The upper portion of fruit nearly globular, from 3 to 6 mm. in diameter, abruptly contracted into a slender stem-like portion seldom exceeding 7 mm. in length; pericarp brown to very dark brown externally, rarely gray, coarsely reticulate, about 0.3 mm. in thickness; 1-locular, 1-seeded, the seed attached at the base of the pericarp and usually not completely filling the loculus; odor aromatic, characteristic; taste strongly aromatic and pungent.

"*Structure.*—Pericarp with an outer epidermis of tabular cells with thickened, undulate outer walls, a nearly continuous hypodermis of stone cells; of wide parenchyma, scattered in which are numerous large, oval secretion cells containing volatile oil and occasionally crystals in the form of short rods, the contents of the secretion cells being colored a deep crimson upon the addition of sulphuric acid; a layer of several rows of collapsed cells in which occurs occasionally a small wood bundle with a few lignified bast-fibers; and an endocarp of one or two rows of isodiametric stone cells; seed-coat of several rows of reddish-brown, tangentially elongated, more or less collapsed cells; perisperm of thin-walled parenchyma cells, more or less polygonal in shape and containing either small starch grains, or globules of fixed oil or occasionally a crystal of calcium oxalate; endosperm small in amount, near the apex of the seed and embedding a very small embryo.

"*Powdered Cubeb.*—Brown to very dark brown. Starch grains numerous, single and compound, the individual grains from 0.002 to 0.012 mm. in diameter; stone cells numerous in palisade-like groups, with rather prominent dark lumina and yellowish, much-thickened, lamellated, porous walls; fragments of wood bundles few, with spiral tracheæ and fibers, the latter from 0.05 to 1.00 mm. in length with blunt, rounded or very much attenuated ends, the walls strongly lignified and with numerous oblique pores.

"Cubeb, powdered or crushed, mixed with a drop of sulphuric acid on glass, and viewed against a white background produces a crimson-red coloration of the acid.

"**Assay.**—Proceed as directed under volatile ether-soluble extractive." *U. S.*

"Nearly globular, about four millimetres in diameter, greyish-brown or nearly black. Pericarp reticulately wrinkled, thin, brittle, and abruptly prolonged at the base into a slender, rounded stalk about one and a half times as long as the globular portion. Seed almost spherical, sometimes much shrivelled, attached by the base. In the transverse section of the pericarp two layers of sclerenchymatous cells, one near the outer, the other near the inner surface, those of the latter being radially elongated and usually arranged in a single row. Strong, aromatic, and characteristic odor; taste warm, aromatic, and somewhat bitter. When 2 grammes of powdered Cubebs are macerated with 20 millilitres of *ether* for twenty-four hours, and shaken occasionally, 10 millilitres of the clear ethereal solution, allowed to evaporate in a flat-bottomed dish, yield a residue which, dried for one hour in a desiccator over *sulphuric acid*, weighs not less than 0.200 gramme. Crushed Cubebs impart a crimson color to *sulphuric acid*. Ash not more than 8 per cent." *Br.*

Commercial cubebs are not infrequently admixed with and entirely substituted by other fruits, some of which contain volatile oils which possess very different properties from the genuine oil of cubeb, being in some instances highly toxic. Hartwich (*A. Pharm.*, 1898) gives the following classification for the identification of spurious fruits:

I. *Fruits of the Piperaceæ having slender stalks.*

- A. STONE CELLS IN EPICARP, ENDOCARP AND DISTRIBUTED IN THE MESOCARP: *Piper ribesioides* Wallich (identical with *Padang Cubeb*). Fruits not colored red with sulphuric acid.
- B. STONE CELLS ONLY PRESENT IN THE EPICARP AND ENDOCARP: *Piper Cubeba* L.f. *Rinoe Katoentjor,* the official variety, which is colored red with sulphuric acid; *Rinoe badak,* distinguished by not being colored red with sulphuric acid; *Piper crassipes* Korthals. Sections not colored red with sulphuric acid.
- C. STONE CELLS PRESENT ONLY IN THE EPICARP: *Piper mollissimum* Blume (*Keboe Cubeb. Karbauw berries*) sections not colored red with sulphuric acid; *Piper venosum* DC. colored red with sulphuric acid.
- D. STONE CELLS ABSENT IN THE PERICARP:
  - (*a*) African varieties: *Piper clussi* DC. sections colored red with sulphuric acid; *Piper guineense* Schum. sections not colored red with sulphuric acid; *Piper borbonense* DC. (*Cubèbe du pays*) sections not colored red with sulphuric acid.
  - (*b*) Indian varieties: None of which are colored red with sulphuric acid; *Piper Lowong* Blume secretion cells colored bluish-green with sulphuric acid; *Ceylon pepper,* secretion cells colored yellow with sulphuric acid; *Piper canium* Blume and *P. phyllostitum* DC.

II. *Fruits of the Piperaceæ without stalks.*
- A. STONE CELLS PRESENT IN EPICARP AND ENDOCARP: *Piper nigrum* L. sections colored red with sulphuric acid.
- B. STONE CELLS ONLY IN THE EPICARP: *Dangdang boeroeng,* a fruit obtained from Java, the origin of which is unknown.
- C. STONE CELLS ABSENT IN PERICARP: *Cubeb from Bangil,* origin unknown. Sections at first colored red with sulphuric acid, then becoming brown.

III. *Fruits obtained from plants belonging to other families than the Piperaceæ.*
1. *Xanthoxylum Budrunga* Wall. (*Fagara Budrunga* Roxb.) (*Rutaceæ*); *Bridelia tomentosa* Bl. (*Euphorbiaceæ*); *Tetranthera citrata* N. v. Esenbeck (*Litsea citrata* Bl.) (*Lauraceæ*); *Daphnidium Cubeba* Nees. (*Lauraceæ*); *Pericampylus incanus* Miers. (*Menispermaceæ*); *Xylopia frutescens* Gaertner. (*Anonaceæ*); *Helicteres hirsuta* Bl. (*Sterculiaceæ*); *Grewia tomentosa* Juss. (*Tiliaceæ*).

Constituents.—The most obvious constituent of cubeb is the volatile oil, the proportion of which yielded by the drug varies from 5 to 20 per cent. It is, as shown by Oglialoro, a mixture of a terpene, boiling at 158° to 163° C., which is present in very small amount, and is probably pinene or camphene, some dipentene, and two oils of the formula $C_{15}H_{24}$, boiling at 262° to 265° C. One of these, known as *cadinene,* is strongly lævogyrate, and yields a crystallized compound having the formula, $C_{15}H_{24}2HCl$, and melting at 118° C., while the other is less lævogyrate, and does not combine with HCl.

The oil distilled from old cubeb on cooling at length deposits large transparent inodorous octahedra of *camphor of cubeb,* $C_{15}H_{26}O$. E. Schmidt found that this camphor melts at 66.5° C.; simply by standing over sulphuric acid, more rapidly on heating, it gave up water and passed into that fraction of cubeb oil which boils at 260° C., of which it is, therefore, simply the hydroxide.

Another constituent of cubeb is *cubebin.* This is an inodorous substance, crystallizing in small needles or scales, melting at 132° C., having a bitter taste in alcoholic solution, it dissolves freely in boiling alcohol, but deposits on cooling, and is abundantly soluble in chloroform. Its composition is $C_{20}H_{20}O_6$. It contains no hydroxyl nor carbinol groups and is not acted upon by oxidizing agents. It is without important physiological properties. Upon decomposition with hydriodic acid in glacial acetic acid solution it yields *cubebinic ether* which, upon redection with sodium in the presence of alcohol, produces *cubebinol.* E. Schaer calls attention to the similarity in reaction between cubebin and veratrine, aconitine, morphine, and digitalin. (*A. Pharm.,* 1887, p. 531.) *Cubebic acid,* a white amorphous substance, is present in the proportion of about 1 per cent.; the therapeutic value of the drug has been attributed as largely due to this constituent. There is also about 3 per cent. of amorphous resin. Cubeb gradually deteriorates by age, and in powder becomes rapidly weaker, in consequence of the escape of its volatile oil. It should be kept whole, and pulverized when dispensed. The powder is said to be sometimes adulterated with that of pimenta.

Uses.—Cubeb in considerable quantities excites the circulation, increases the heat of the body, and sometimes occasions headache and giddiness. At the same time it frequently produces an augmented flow of the urine, to which it imparts a peculiar odor. Among its effects are also occasionally nausea and moderate purging, and it is said to cause a sense of coolness in the rectum during the passage of the feces. We have no evidence that it was known to the ancients.

Cubeb, because of its local irritant action, acts as a stimulant to the mucous membranes. Its active principles appear to be capable of absorption and elimination through the kidneys exerting their characteristic effects upon the mucous membrane of the genito-urinary tract. It is probable also that it possesses some antiseptic virtues. Formerly it was widely used in the treatment of a large variety of inflammatory complaints but at present is used as an internal remedy only in the latter stages of *gonorrheal urethritis* after the subsidence of the first inflammatory symptoms, and occasionally in *chronic bronchitis.* Even for these purposes its use is passing out of vogue. It is a widely employed local remedy in the form of lozenges for the relief of various relaxed conditions of the throat.

Dose, of powdered cubeb, ten grains to one drachm (0.65–3.9 Gm.).

CUPRI SULPHAS. U. S., Br.

CUPRIC SULPHATE Cupr. Sulph. [Copper Sulphate]

"Cupric Sulphate contains not less than 63 per cent. and not more than 66.8 per cent. of $CuSO_4$, corresponding to not less than 98.5 per cent. of the crystallized salt [$CuSO_4.5H_2O$]." *U. S.* "Copper Sulphate, $CuSO_4,5H_2O$, may be obtained by the interaction of sulphuric acid, copper or copper oxide, and water." *Br.*

Cuprum Vitriolatum; Blue Vitriol, Roman Vitriol, Blue Stone; Sulfate de Cuivre, *Fr. Cod.;* Vitriol bleu, Couperose bleu, *Fr.;* Cuprum Sulfuricum, *P. G.;* Schwefelsaures Kupfer, Kupfersulfat, Kupfervitriol, Blauervitriol, Blauer Galitzenstein, *G.;* Solfato di rame, Vitriolo di rame, *It.;* Sulfato cuprico, Vitrolo azul, *Sp.*

Preparation.—Copper sulphate occasionally exists in nature, in solution in the water which flows through copper mines. In this case the salt is procured by merely evaporating the waters which naturally contain it. Another method of obtaining it is to roast the native sulphide in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. Too high a temperature must be avoided during the roasting process to avoid the production of hard masses from which the copper is extracted with great difficulty, subsequent chlorination of the product sometimes being necessary. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods contains a little ferric sulphate, from which it may be freed by adding either an excess of cuprous oxide, which precipitates ferric oxide, or recently precipitated copper subcarbonate, which causes the deposition of the iron as a carbonate. (*A. J. P.*, xxxiv, 507.) A third method is to dissolve copper scales to saturation in sulphuric acid contained in a wooden vessel lined with sheet lead. The scales consist of metallic copper mixed with oxide, and are produced in the process for annealing sheet copper.

Most of the copper sulphate produced at present is obtained as a by-product by the gold, silver, and copper refiners. The production of copper sulphate in the United States is very large, and there is a considerable exportation.

In the U. S. Pharmacopœia copper sulphate is presumed to be obtained pure from the manufacturer; the British Pharmacopœia suggests the method in which it may be prepared, without entering into the details of the process. The German Pharmacopœia has two kinds official, *Cuprum sulfuricum,* which corresponds with the former *Cuprum sulfuricum purum,* and *Cuprum sulfuricum crudum,* or commercial sulphate.

Description and Physical Properties.—"Deep blue, triclinic crystals or a blue, granular powder. It is odorless, and has a nauseous, metallic taste. It is slowly efflorescent in dry air. One Gm. of Cupric Sulphate is soluble in 2.5 cc. of water, 500 cc. of alcohol, and in 2.8 cc. of glycerin, at 25° C. One Gm. is soluble in 0.5 cc. of boiling water.

"When heated to 30° C., Cupric Sulphate loses part of its water of crystallization and is converted into a pale, blue, amorphous powder. More water is lost at 100° C., and finally at 200° C. a white, anhydrous powder remains. At a still higher temperature, sulphur dioxide and oxygen are given off, and a residue of black cupric oxide remains. An aqueous solution of the salt (1 in 20) has a blue color, and is acid to litmus paper. An aqueous solution of the salt (1 in 10) responds to the reactions for copper, and for sulphates.

"Dissolve 1 Gm. of Cupric Sulphate in 50 cc. of distilled water, add 1 cc. of diluted hydrochloric acid, and pass hydrogen sulphide through the solution until all of the copper is precipitated: upon evaporating the filtrate and igniting, the weight of the residue does not exceed 0.003 Gm. (*other metals*).

"**Assay.**—Dissolve about 1 Gm. of Cupric Sulphate, accurately weighed, in 50 cc. of distilled water, add 4 cc. of acetic acid and 3 Gm. of potassium iodide, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01596 Gm. of $CuSO_4$. Cupric Sulphate may also be assayed by the electrolytic method.

"Preserve in well-closed containers." *U. S.*

"Blue triclinic prisms. Soluble in 3.5 parts of *water,* very soluble in *glycerin,* almost insoluble in *alcohol* (90 per cent.). The aqueous solution is acid to *litmus.* Yields the *reactions* characteristic of copper and of sulphates. Yields no characteristic *reactions* for lead, zinc or aluminium. *Arsenic limit* 10 parts per million. Contains not more than 0.1 per cent. of iron, calculated as iron, Fe, when tested by the following process:—Dissolve 5 grammes in 25 millilitres of *water,* add 2 millilitres of *nitric acid,* heat to boiling, cool, and add *strong solution of ammonia* until the precipitate which first forms is redissolved and the liquid has a distinct odor of ammonia. Filter. Wash the filter paper thoroughly with *water* made alkaline with *solution of ammonia,* redissolve in *hydrochloric acid* any precipitate that has been collected, reprecipitate with *solution of ammonia,* collect, wash, dry, ignite, and weigh the residue. It weighs not more than 0.007 gramme." *Br.*

When heated, copper sulphate first liquefies in its water of crystallization, and then dries and becomes white. If the heat is increased, it next undergoes the igneous fusion, and finally, at a high temperature, loses its acid, cupric oxide being left. Four of the molecules of water of crystallization can be driven off at 100° C., but the fifth goes off only at a temperature of from 220° to 240° C., when the anhydrous salt remains. Potassium hydroxide, sodium hydroxide, and ammonia throw down from it a bluish-white precipitate of hydrated cupric oxide, which is immediately dissolved by an excess of the last mentioned alkali, forming a rich deep blue solution, called *aqua sappharina.* It is decomposed by the alkaline carbonates, and by borax, lead acetate and subacetate, ferric acetate, silver nitrate, mercuric chloride, potassium tartrate, and calcium chloride, and it is precipitated by all astringent vegetable infusions. If it becomes very green on the surface by the action of the air, it contains ferric oxide. This oxide may also be detected by ammonia, which will throw it down along with the copper oxide, without taking it up when added in excess. When copper sulphate is obtained from the *dipping liquid* of manufacturers of brass or German silver ware, it is always contaminated with zinc sulphate, as pointed out by S. Piesse. This liquid is at first a mixture of sulphuric and nitric acids, but becomes, at last, nearly saturated with copper. When zinc is present in copper sulphate, it will be taken up by solution of potassium hydroxide added in excess, from which it may be thrown down, after filtration, in white flocks, by a solution of bicarbonated alkali.

The industrial uses of copper sulphate are many and important. It is used in copper plating, in dyeing, in calico printing, in the manufacture of numerous pigments and in water purification and in the combating of plant diseases caused by certain low forms of plant or animal life.

Copper sulphate is incompatible with alkalies and liberates iodine from iodides.

Uses.—Copper sulphate is irritant or mildly escharotic, and when in diluted solution, stimulant and astringent. At one time it was given in *epilepsy* and other nervous diseases, but at present it is never used internally, except for its influence upon the gastro-intestinal mucous membrane. In *chronic diarrhea* with ulceration it is sometimes a useful remedy. In doses of 5 grains it acts as a powerful, prompt emetic, without causing general depression or much nausea, but is too irritant to be used freely; it is useful as an emetic in *phosphorus poisoning* because it not only empties the stomach but acts also as a chemical antidote to the phosphorus. Externally it is employed in solution as a stimulant to ill-conditioned *ulcers,* as an escharotic for destroying *warts,* fungous *granulations,* and callous edges, and as a styptic to bleeding surfaces. It is found, in not a few instances, to promote the cicatrization of ulcers, and is not infrequently employed, with that view, as a wash for *chancres.* Bevan (*S. M.,* 1905, p. 558) has used copper sulphate successfully in *actinomycosis.* He gave from one to three grains (0.065–0.2 Gm.) daily and applied a 1 per cent. solution to the ulcerated area.

Copper sulphate is highly poisonous to certain of the lower forms of vegetable life, thus it has been found serviceable for destroying the algæ in ponds. While in general its antibacterial properties are not very powerful it seems to be especially poisonous towards the *Bacillus typhosus,* Gildersleeve (*A. J. M. S.,* 1905, cxxxix, p. 757) having shown that as little as one part to a million is sufficient to destroy this bacterium in a period of three hours. It was at one time suggested as a means for purifying drinking water but is not practically available because the presence of various impurities destroys its action.

The preparation called *Cuprum Aluminatum* (*lapis divinus—pierre divine*) is made, according to the French Codex, by mixing, in powder, three ounces, each, of copper sulphate, potassium nitrate, and alum, heating the mixture in a crucible, so as to produce aqueous fusion, then mixing in a drachm of powdered camphor, and, finally, pouring out the whole on an oiled stone to congeal. The mass, when cold, is broken into pieces, and kept in a well-stoppered bottle. It is often desirable to employ copper sulphate, as a caustic, in the form of pencil. Its tendency to effloresce interfers with its use in this way in the pure state. Llovet recommends for the purpose a mixture of one part of potassa-alum and two of copper sulphate, which are to be first powdered, and then gradually melted together in a porcelain vessel, and poured into moulds made of bronze. Another mode of preparing *pencils of copper sulphate* is to rub briskly together four parts of that salt and one of borax, and to mould the plastic mass which results, into the desired form. An elongated cone is the best form, made by selecting suitable crystals and turning them in a lathe to the desired form; or they may be made by filing the crystals, and finishing with sand paper.

Dose, of copper sulphate, as an astringent, one-fourth of a grain (0.016 Gm.); as an emetic, five grains (0.32 Gm.), repeated in fifteen minutes if necessary, but not oftener than once. As a stimulant wash, the solution may be made of the strength of two, four, or eight grains to the fluidounce of water. For its effects as a poison, see *Cuprum.*

CUPRUM.

COPPER

Cu = 63.57.

"Fine Copper wire, about No. 25 wire gauge or about 0.02 inch." *Br.,* 1885.

Cupreum Filum: Fil de Cuivre, Cuivre, *Fr.;* Kupfer, Kupferdraht, *G.;* Rame, *It.;* Cobre, *Sp.*

This metal is very generally diffused in nature, and exists principally in four states; as native copper, as an oxide, as a sulphide, and as a salt. Its principal native salts are the sulphide (*chalcopyrite* $CuS.FeS$, and *chalcocine* Cu_2S), silicate, carbonate (*malachite* $CuCO_3.3Cu(OH)_2$, and *azurite* $2CuCO_3.Cu(OH)_2$), arsenate, oxide (*cuprite* Cu_2O), and phosphate. In the United States it occurs in various localities, but especially in the neighborhood of Lake Superior, in Montana, Arizona, Alaska and East Tennessee. The principal producing copper mines of Europe are those of Sweden, Spain and Portugal and Germany and the Ural Mountains. Chili, China and Japan are also relatively large producers at present. It is one of the metals used by man from remote periods of antiquity.

The total production of copper in the United States has increased very rapidly in recent years, and now is more than two-thirds of the world's annual production. The three most productive states are Arizona, Montana, and Michigan, in the order named.

Properties.—Copper is a brilliant, sonorous metal, of a reddish color, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable odor when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8.92 to 8.95, and its fusing point 1080° C. Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well characterized oxides, a red suboxide, better known as *cuprous* oxide, Cu_2O, and a black oxide, known as *cupric* oxide, CuO. While a cuprous chloride, iodide, and sulphide are known, it is the cupric oxide chiefly that unites with the several acids to form the copper salts. With metals copper forms numerous alloys, of which that with zinc, called *brass,* and that with tin, called *bronze,* are the most useful. *Bell metal, gun metal, delta metal, phosphor bronze, statuary bronze, silico bronze, manganese bronze,* and *German silver* are other alloys in frequent use in which copper is the predominating constituent.

Characteristics.—Copper is recognized by its color, and the effects of tests on its solution in nitric acid. This solution, with potassium hydroxide, sodium hydroxide, and ammonia, yields a blue precipitate, soluble in excess of the latter alkali, with which it forms a deep azure-blue liquid. Potassium ferrocyanide occasions a brown precipitate of copper ferrocyanide, and a bright plate of iron immersed in the solution of copper nitrate immediately becomes covered with a film of metallic copper. Thoms (*Zeit. An. Chem.,* 94, 464) asserts that if to a solution, too dilute to give a sensible reaction with potassium ferrocyanide, be added a solution of potassium iodide, a yellow coloration is produced which becomes violet with starch paste. This test, in absence of deoxidizing agents, will show as little as 1 to 500,000. Potassium ferrocyanide is a very delicate test for minute portions of copper in solution. Another test, proposed by Verguin, is to precipitate the copper in the metallic state on platinum by electro-chemical action. For this purpose a drop of the (acid) liquid to be examined is placed on a slip of platinum foil, and a slip of bright iron is brought in contact with the platinum and the liquid. If copper be present it will be instantly precipitated on the surface of the platinum. Copper compounds when present in food or drug products in appreciable amounts may be detected by the simple test of immersing a bright piece of steel or iron (as a knitting needle or spatula) into the material which has been brought to a pasty condition and acidulated with hydrochloric acid. The copper will be deposited upon the iron or steel in the form of a very thin easily perceptible film.

Action on the Animal Economy.—Copper in its pure state is nearly inert, but in combination it is highly deleterious. Nevertheless, a minute portion of the metal has been found in the human body. Wackenroder found copper in the blood of man, but does not consider it a constant and normal constituent. He also detected this metal in the blood of domestic animals living on a mixed diet, but not in their blood when nourished on vegetable food only. It has been found in the feathers of certain birds, as of a grass-green paroquet from Australia, which is said to frequent districts of the country where copper is found.

The soluble combinations of copper, when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain in the stomach and bowels; frequent black and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine, and burning pain in voiding it; violent headache; cramps, convulsions, and finally death. The best antidote is potassium ferrocyanide, given freely, which forms with the poison the insoluble copper ferrocyanide. Soap and alkalies are also antidotal. Before the antidote can be procured, large quantities of albuminous substance of milk or white of eggs should be given mixed with water, which act favorably by forming copper caseinate and copper albuminate, respectively, but these compounds should be evacuated as soon as possible by vomiting and purging. Should vomiting not take place, the stomach tube may be employed.

There is some difference of opinion as to whether the prolonged injection of copper can give rise to a chronic type of poison. Although some of the older writers attributed various cachectic symptoms to copper poisoning, the experiments of Huber (*J. P. Ex. T.,* 1918, xi, p. 303) who tested the effects of prolonged administration of a large number of salts of copper from the lower animals, without noting any ill effects, is in harmony with the clinical evidence that if copper has any deleterious influence upon the general health, it is very slight.

In medico-legal examinations, where cuprous poisoning is suspected, Orfila recommends that the viscera be boiled in distilled water for an hour, and that the matter obtained by evaporating the filtered decoction to dryness be carbonized by nitric acid. The carbonized product will contain the copper. By proceeding in this way there is no risk of obtaining the copper which may happen to pre-exist in the animal tissues. This method of search is preferable to that of examining the contents of the stomach and intestines, from which copper may be absent, while it may have penetrated the different organs by absorption, especially the abdominal viscera.

Vessels of copper which are not coated with tin should not be used in pharmaceutical or culinary operations, for although the metal uncombined is inert, yet the risk is great that the vessels may be acted on and a poisonous salt formed.

CYPRIPEDIUM. N. F.

CYPRIPEDIUM Cypriped. [Lady Slipper Root]

"Cypripedium consists of the dried rhizome and roots of *Cypripedium bulbosum* Miller, *Cypripedium pubescens* Willdenow, or of *Cypri-*

UNIVERSITY OF ILLINOIS
LIBRARY-CHEMISTRY

pedium parviflorum Salisbury (Fam. *Orchidaceæ*). Cypripedium contains not more than 3 per cent. of other parts of the same plant or other foreign organic matter and yields not more than 6 per cent. of acid insoluble ash." *N. F.*

Lady's Slipper; Rhizoma Cypripedii; Yellow Lady's Slipper Root; Yellow Indian Shoe; Yellow Moccasin Flower; Yellow Noah's Ark; Venus' Shoe; Male Nervine; American Valerian; Racine de Cypripède jaune, Valériane américaine, *Fr.;* Gelbfrauenschuhwurzel, *G.*

Under the common name of *lady's slipper,* or *moccasin plant,* about 30 species of *Cypripedium* inhabit the woods in different parts of the north temperate zone. They are small plants, with large, many-nerved, plaited leaves, sheathing at the base, and large, often beautiful terminal flowers, of a shape not unlike the Indian moccasin, whence they derive one of their common names. Their generic name of *cypripedium* (Κύπρις, *Venus,* and πόδιον, *sock*) had a similar origin. Several of them have been used by American physicians, the root being the part employed. R. P. Stevens of Ceres, Pennsylvania, says of them that he has found the *C. reginæ* Walt. (*C. spectabile* Salisb.), and *C. acaule* Ait., especially when growing in dark swamps, to be possessed of narcotic properties, and to be less safe than the *C. parviflorum* Salisb. The rhizomes and roots of the two species, *C. hirsutum* and *C. parviflorum* are indiscriminately found in commerce and sold under the same name.

Cypripedium hirsutum Mill. (*C. pubescens* Willd.), or *Large Yellow Lady's Slipper,* has a simple, often flexuous, pubescent, leafy stem, from one to two feet high. The leaves are pubescent, ovate-lanceolate, acuminate, narrowing at the base, about four or five inches long by two in breadth, alternate, sessile, and sheathing. The flower is usually solitary and terminal, with four divisions of the perianth, the two outer cohering nearly to the apex, the inner longer, narrower, undulatory or twisted, and the lip an inch or two in length, swelling sac-like, and of a yellow color. The fruit is an oblong capsule, tapering at each end, recurved, pubescent, and peduncled. The plant is indigenous, growing abundantly in rich, moist woods from Newfoundland to Georgia, west to Minnesota and Eastern Kansas.

Cypripedium parviflorum Salisb., or *Small-flowered Yellow Lady's Slipper,* is a perennial plant with a leafy stem, a foot or two in height, and comparatively small, bright yellow flowers, appearing in May. The specific character of the flower is that the lobe of the style is triangular and acute; the outer petals are oblong-ovate and acuminate; the inner linear and contorted; the lips shorter than the petals, and compressed. This species has the same range as *C. hirsutum.*

The rhizomes and roots are gathered after the flowering of the plant in the spring, washed and dried. The commercial supplies are obtained from Michigan, Wisconsin, North Carolina, Kentucky, Virginia, Indiana and Missouri.

Description and Physical Properties.—"*Unground Cypripedium.*—Rhizome of horizontal growth, curved, 3 to 10 cm. long, 2 to 6 mm. thick, orange-brown to dark brown, the upper side showing numerous circular, cup-shaped scars, closely covered below with simple, wiry roots, the latter varying from 3 to 15 cm. in length; fracture of rhizome short, white; that of roots somewhat fibrous. Odor distinct, heavy; taste sweetish, bitter, and somewhat pungent.

"*Structure.*—Rhizome: epidermis composed of small cells with reddish brown walls; cortex of about twelve layers of thick-walled parenchyma cells, the latter being filled with starch or resin, a few containing raphides of calcium oxalate; stele without endodermis and consisting of irregularly distributed concentric fibro-vascular bundles surrounded by thick-walled porous parenchyma cells, the latter containing starch, resin, or calcium oxalate in raphides, no distinct pith present. Root; epidermis of small cells with reddish brown walls usually without root hairs, hypodermis of a single layer of small cells with yellowish walls; about seven layers of parenchyma cells containing starch, resin, or calcium oxalate in raphides; stele composed of from five to eight radial fibro-vascular bundles with the sieve in small groups adjoining a pericambium composed of a single layer of thin-walled cells; endodermis continuous, and composed of thin-walled cells, except opposite the sieve where two or three cells are thickened, more or less lignified and fiber-like.

"*Powdered Cypripedium.*—Yellowish brown; numerous rounded or somewhat angular, simple and compound starch grains up to 0.014 mm. in diameter; calcium oxalate in raphides up to 0.070 mm. in length and occurring isolated or in bundles, occasionally imbedded in a mucilage-like plasma; tracheæ spiral, scalariform, or with simple or bordered pores; a few tracheids, fibers, long, thin-walled and lignified; a few non-lignified, thick-walled fibers; fragments of epidermal tissue composed of elongated cells with reddish brown walls; groups of thick-walled parenchyma cells with numerous simple pores, and containing starch, resin, or calcium oxalate." *N. F.*

Locally poisonous properties have been attributed to *C. reginæ* Salisb. and *C. parviflorum* var. *pubescens* (see *Geol. Nat. Hist. Survey, Minnesota Bull.,* 9, part i), but it has been shown that the secretion from the glandular hairs simply exerts an irritant action.

Cypripedium has a somewhat aromatic odor, which diminishes by time, and a bitter, sweetish, peculiar, and in the end somewhat pungent taste.

Cypripedium contains a volatile oil, tannin and a bitter principle, perhaps glucosidal (Beshore, *A. J. P.,* 1887). The eclectic preparation *cypripedin* is said to be a resinoid, obtained by precipitating with water a concentrated tincture of the rhizome.

Uses.—Cypripedium appears to be a gentle nervous stimulant or antispasmodic, and has been used for the same purposes as valerian, though less powerful. E. Ives of New Haven, Conn., commends the remedy in *hypochondriasis* and *neuralgia.* It may be used in powder, infusion, or tincture.

Dose, of the powder, fifteen grains (1.0 Gm.), three times a day. The resinoid, obtained by precipitating the tincture, has been given in doses varying from half a grain to three grains (0.032 to 0.20 Gm.).

Off. Prep.—Fluidextractum Cypripedii, *N. F.*

DAMIANA. N. F.

DAMIANA [Turnera]

"Damiana is the dried leaf of *Turnera diffusa* Willdenow et Schultes, or of *Turnera aphrodisiaca* Ward (Fam. *Turneraceæ*). Damiana contains not more than 15 per cent. of its stems, not more than 3 per cent. of other foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

The genus *Turnera* is represented by about 85 species of tropical and subtropical American, African, and Madagascar plants that vary in habit from herbs, subshrubs or shrubs. Only one species, *Turnera diffusa* and its variety *aphrodisiaca* yield the drug, *damiana.* Both of these are shrubs indigenous to southern California, Mexico, South America and the West Indies. The commercial supplies of Damiana are imported chiefly from Bolivia and Mexico.

Description and Physical Properties.—"*Unground Damiana.*—Obovate to lanceolate, 10 to 25 mm. long and from 4 to 10 mm. wide, short-petioled, obtuse or acute at the apex, and with a short, cuneate base; sharply 2- to 10-toothed on each side; the veins ascending, generally strong, straight and simple and running to the sinuses of the teeth, but sometimes branched and sending the branches into teeth; the upper surface smooth and light green or yellowish green, the lower glabrous or with a few hairs on the ribs (*Turnera aphrodisiaca*) or densely tomentose over the entire surface (*Turnera diffusa*). Intermixed with the leaves are frequently found some reddish twigs, the young tips and buds of which are grayish with appressed pubescence (*Turnera aphrodisiaca*) or white floccose (*Turnera diffusa*), also flower buds, yellowish flowers, and globose pods. Odor aromatic; taste characteristic, aromatic and resinous.

"*Powdered Damiana.*—Light yellowish green; fragments of epidermal cells and mesophyll of leaf, the cells of the former with somewhat wavy, vertical walls and associated with stomata up to 0.030 mm. long, numerous rough simple hairs, up to 0.900 mm. in length and 0.030 mm. in width at the base, with a narrow lumen usually distinct at the base only and with heavy, mostly non-lignified walls, often curved near the base so that the major portion of the hair lies nearly parallel to the surface of the stem or leaf; fragments of the periderm from the stems composed of somewhat rectangular cells up to about 0.070 mm. in length and about one-third as broad, with square or somewhat pointed ends, with few broadly elliptical stomata about 0.030 mm. long; subepidermal cells from the stem resembling those of the epidermis in shape but with lignified walls; tracheæ, spiral, up to 0.020 mm. wide, or with bordered pores and up to about 0.035 mm. wide; tracheids from stem few; strongly lignified, thick-walled sclerenchyma cells or fibers few; lignified pith-parenchyma with large simple pores; numerous crystals of calcium oxalate in rosettes up to 0.030 mm. in diameter and occasionally in prisms; starch grains few, simple, up to 0.012 mm. in diameter." *N. F.*

Parsons (*A. Pharm.*, 1881, p. 133) obtained 0.2 per cent. of a volatile oil; 8.06 of a soft resin, fixed oil and chlorophyll; 3.46 per cent. of tannin; 7.08 per cent. of a bitter principle; 6.39 per cent. of a hard brown resin; 10 per cent. of extractive; 13.5 per cent. of a gum; 6.15 per cent. of starch, etc.

The leaves of the composite plant *Aplopappus discoideus* DC. (*Bigelovia Veneta* Gray) were, formerly, also sold under the name of damiana and are found occasionally as adulterants in the drug of commerce.

Uses.—Although damiana has achieved some repute in the treatment of sexual *impotence,* it is worthy of note that it is always given in conjunction with strychnine, phosphorus or some other stimulant; it is probably nothing more than a feeble tonic.

Dose, one-half to one drachm (2–4 Gm.) of the leaves, either in the form of infusion or fluidextract.

Off. Prep.—Fluidextractum Damianæ, *N. F.*

DATURÆ FOLIA. Br.

DATURA LEAVES

"Datura Leaves are the dried leaves of Datura fastuosa, *Linn.*, var. alba, *Nees* and also of Datura Metel, *Linn.*" *Br.*

DATURÆ SEMINA. Br.

DATURA SEEDS

"Datura Seeds are the dried seeds of Datura fastuosa, *Linn.*, var. alba, *Nees.*" *Br.*

The genus *Datura* consists of fifteen species, which are distributed throughout the warmer portions of the whole world, the greatest number being found in tropical America. Nearly all of them are used locally in medicine. The plants vary from herbs to shrubs and even trees. The leaves of *Datura Stramonium* L. are official in the U. S. Pharmacopœia. (See *Stramonium.*)

Datura fastuosa L. is an annual herb attaining a height of 4 to 5 feet which is indigenous to India but naturalized in the tropics of both hemispheres. It is characterized by possessing ovate-lanceolate, acuminate, toothed or wavy-margined leaves, trumpet-shaped flowers, up to

7 in. in length and erect; spiny, subglobular, capsular fruits. The var. *alba* Nees has white or nearly white flowers.

Datura Metel L. is another Indian annual herb somewhat resembling *D. fastuosa.* It differs from the latter in possessing entire or only slightly toothed, pubescent leaves and nodding capsules. The flowers are white.

Datura meteloides DC. is a perennial herb in the wild state but an annual as cultivated in temperate regions. It is native to northern Mexico and the southwestern United States and is especially characterized by its slender, forked, glaucous branches, unequally ovate, nearly entire leaves, acute at base and apex, its fragrant white flowers which are suffused with violet, and its succulent, erect and prickly capsules.

Of the varieties of *D. fastuosa,* the British Pharmacopœia recognizes that known as *alba.* From it the Thugs prepared the poison *Dhât* (whence is derived the generic name), which they used to stupefy their victims.

The *leaves* are described as "Brownish or yellowish-green, attaining twenty centimetres in length and thirteen centimetres in breadth; ovate, acuminate, with sinuate-dentate margins and long petioles; often unequal at the base; bearing scattered glandular or simple hairs. Characteristic odor; taste bitter." *Br.*

The trumpet-shaped corolla, together with the stamens, is sometimes found mixed with the leaves. The drug has a slight unpleasant odor, and a bitter taste.

The *seeds* are "yellowish-brown, somewhat wedge-shaped, flattened, with rounded, thickened, furrowed, wavy margins; from four to five millimetres broad and about one millimetre thick. Hilum large, extending from about the middle to the acute end of the seed. Surface finely pitted and reticulated. Endosperm narrow and translucent, enclosing a curved embryo. No odor; taste slightly bitter." *Br.*

Constituents.—The *D. fastuosa* differs chemically from the *D. Stramonium,* which is official in the U. S., in that its dominant alkaloid is scopolamine (Andrews, *Tr. Chem. Soc.,* 1911, xcix, p. 1876), but it also contains traces of hyoscyamine. The proportion of alkaloid in the leaves is usually about 0.12 per cent., and in the seeds approximately double this quantity (Schmidt, *A. Pharm.,* 1906, ccxliv, p. 66). The alkaloids of the *D. Metel* and of the *D. meteloides* are very similar to those of the official species, but Pyman and Reynolds (*Tr. Chem. Soc.,* 1908, xciii, p. 2077 and 1912, ci, 946) have found small amounts of two new alkaloids—*meteloidine* and *nor-hyoscyamine.*

Uses.—While this drug produces effects more or less similar to those of belladonna its precise action has not been clearly determined. It is used in India to a considerable extent as a criminal poison; cases have been reported by Banerja (*Indian Med. Gaz.,* 1885, xx, p. 209) and by Gimlette (*B. M. J.,* 1903, i, p. 1137). In India the *Datura fastuosa* leaves have been used for the same purposes as the stramonium leaves.

Off. Prep.—Tinctura Daturæ Seminum, *Br.*

DECOCTA. U. S.

DECOCTIONS

Tisanes par décoction, Décoctions, *Fr.;* Abkochungen, *G.;* Decotti, *It.;* Cocimiento, *Sp.*

Decoctions are solutions of vegetable principles, obtained by *boiling* the substances containing these principles in water. Vegetable tissues generally yield their water-soluble constituents more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the principles which are to be extracted are not injured by heat. The process should be conducted in a covered vessel. The boiling, moreover, should not, as a rule, be long continued for the same reason. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful. Should the physician not happen to prescribe this preliminary preparation, the pharmacist should not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavorable to its activity, and in still others inert matter is too freely extracted, and in the large class of drugs containing resinous principles, water is of very little use in extracting the virtues of the drug. In some of these instances, infusion is preferable to decoction. Besides, by the latter process more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place and the liquid is rendered turbid, and this constitutes the greatest objection to this class of preparations. When the active principle is thus dissolved is excess, the decoction should always be strained while hot, so that the matter which separates on cooling may be mixed again with the fluid by agitation at the time of administering the remedy. In compound decoctions several of which were vary popular at one time, the ingredients were advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, if one of them owed its activity to a volatile principle, the plan followed, at the close of the process, was to pour upon it the boiling decoction of the other ingredients, and allow the liquor to cool in a covered vessel.

As a rule, glass or earthenware vessels should be preferred, as those made of metal are sometimes corroded by the ingredients of the decoction, which thus become contaminated. Vessels of block tin are preferable to those made of copper, brass, or zinc; but iron pots should not be used where astringent vegetable substances are concerned.

Decoctions, on account of the presence of fermentable constituents and the absence of any preservative solvent such as alcohol or glycerin are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, when the weather is warm, for a longer period than forty-eight hours.

The tendency of modern medicine and pharmacy has been decidedly against the employment of decoctions; their nauseous taste, bulky dose, repulsive appearance, and non-permanent character have been powerful reasons for causing their retirement, while the use of tinctures and fluidextracts has largely increased.

There is, at present, no decoction specifically recognized by the U. S. Pharmacopœia, but the following general formula is given:

"Decoctions must be freshly made, and when their strength is not otherwise directed, they are to be prepared by the following general formula: The Drug, coarsely comminuted, 50 Gm.; Water, a sufficient quantity to make 1000 cc. Place the drug in a suitable vessel provided with a cover, pour upon it 1000 cc. of cold water, cover it well, and boil for fifteen minutes. Then allow it to cool to about 40° C., express, strain the expressed liquid, and pass enough cold water through the strainer to make the product measure 1000 cc.

"Caution.—The strength of decoctions of energetic or powerful drugs should be specially directed by the physician." *U. S.*

DECOCTUM ACACIÆ CORTICIS. Br.

DECOCTION OF ACACIA BARK

"Acacia Bark, bruised, 60 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Acacia Bark with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in India as an astringent gargle, lotion, or injection. The *dose* is from four fluidrachms to two fluidounces (15–60 cc.).

DECOCTUM AGROPYRI. Br.

DECOCTION OF COUCH GRASS [Decoction of Triticum]

"Couch Grass, cut small, 50 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Couch Grass with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in *cystitis* and *urinary diseases. Dose,* four fluidrachms to two fluidounces (15–60 cc.).

DECOCTUM GOSSYPII RADICIS CORTICIS. Br.

DECOCTION OF COTTON ROOT BARK

"Cotton Root Bark, bruised, 200 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Cotton Root Bark with two thousand *millilitres* of the Distilled Water, in a suitable vessel, until the volume is reduced to one thousand *millilitres;* strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used as an emmenagogue and in *uterine hemorrhage. Dose,* from four fluidrachms to two fluidounces (15–60 cc.).

DECOCTUM ALOES COMPOSITUM. Br.

COMPOUND DECOCTION OF ALOES

Tisane (Décocté) d'Aloès composée, *Fr.;* Zusammengesetztes Aloëdecoct, *G.*

"Extract of Aloes, 10 *grammes;* Myrrh, Potassium Carbonate, of each, 5 *grammes;* Extract of Liquorice, 40 *grammes;* Compound Tincture of Cardamoms, 300 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Reduce the Extract of Aloes and the Myrrh to coarse powder, and boil them and the Potassium Carbonate and the Extract of Liquorice with four hundred *millilitres* of Distilled Water in a covered vessel for five minutes; cool; add the Tincture of Cardamoms; set aside for two hours; strain through flannel; pass sufficient Distilled Water through the strainer to produce the required volume." *Br.*

This is essentially the former process of the British Colleges. The effect of the alkaline carbonate is, by combining with the resin of the myrrh and the insoluble portion of the aloes, to render them more soluble in water, while the licorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by adding preservative qualities. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*P. J.*, xiv, 491.) J. F. Brown proposes to prepare a concentrated decoction which keeps for a long time unchanged. (*C. D.*, 1896, 425.)

Long boiling impairs the purgative property of aloes, and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself; it is also more tonic and cordial, from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the potassium carbonate. It is given as a gentle cathartic, tonic, and emmenagogue, and is especially useful in *dyspepsia, habitual constipation,* and atonic *amenorrhea.* The decoction should not be combined in prescription with acids, acidulous salts, or other bodies incompatible with the alkaline carbonate.

Dose, from one-half to two fluidounces (15–60 cc.).

DECOCTUM HÆMATOXYLI. Br.

DECOCTION OF LOGWOOD

Tisane (Décocté) de Bois de Campêche, *Fr.;* Blauholz Abkochung, *G.*

"Logwood, in chips, 50 *grammes;* Cinnamon Bark, bruised, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Logwood with twelve hundred *millilitres* of Distilled Water in a suitable vessel for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition, but there might be circumstances under which it would be better omitted, and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in *diarrheas* of relaxation.

Dose, from one-half to two fluidounces (15–60 cc.).

DECOCTUM ISPAGHULÆ. Br.

DECOCTION OF ISPAGHULA

"Ispaghula, bruised, 15 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Ispaghula with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used as a demulcent drink in India for *diarrhea.*

Dose, from four fluidrachms to two fluidounces (15–60 cc.).

DECOCTUM SAPPAN. Br.

DECOCTION OF SAPPAN

"Sappan, in chips, 50 *grammes;* Cinnamon Bark, bruised, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Sappan with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used like logwood decoction in India as an astringent in *diarrhea* in *doses* of four fluidrachms to two fluidounces (15–60 cc.).

DELPHINIUM. N. F.

LARKSPUR SEED Delphin.

"Larkspur Seed is the dried, ripe seed of *Delphinium Ajacis* Linné (Fam. *Ranunculaceæ*). Larkspur Seed contains not more than 2 per cent. of foreign seeds or other foreign organic matter." *N. F.*

Knight's Spur; Lark's Heel; Lark's Claw; Staggerweed; Flores Calcatrippæ; Rittersporn, *G.;* Dauphinelle, Pied d'Allouette, *Fr.*

Both of the official species of Larkspur are natives of Europe but have become sparingly naturalized in the Middle Atlantic States. They differ from our native species in being annuals instead of perennials having only two petals instead of four and a single pistil. The leaves are divided into narrowly linear segments. The delphiniums are very closely related to the staphisagria, indeed their seeds are often substituted for this. The *D. Consolida* seeds do not appear to be commercially common.

Description and Physical Properties.—"*Unground Larkspur Seed.*—Irregularly tetrahedral, or somewhat triangulate, acute at one end, obtuse or rounded at the other, about 2 mm. in length and equally broad or slightly narrower; surface black or blackish brown, occasionally grayish with from 8 to 12 rows of centrifugally elongated epidermal cells transversely encircling the seed and forming wavy continuous vertical walls or ruffles occasionally intersecting and with narrow channels between; seed-coat crustaceous; endosperm whitish, fleshy and oily; embryo small, in fleshy endosperm. Odor very faint; taste bitter, afterward biting and acrid.

"*Structure.*—Epidermis of non-lignified cells with thick light-yellowish walls some of which extend outwardly forming more or less continuous, ruffle-like projections; several layers of cells containing a dark brown pigment; inner seed-coat composed of non-lignified cells with thick, porous walls; occasionally cells near the micropyle containing a few starch grains; a large endosperm of thick-walled parenchyma, the cells being filled with fixed oil and aleurone grains.

"*Powdered Larkspur Seed.*—Gray-brown. Numerous fragments of endosperm parenchyma filled with fixed oil and aleurone grains, the latter up to 0.012 mm. in length; fragments composed of elongated epidermal cells, the latter up to about 0.045 mm. in diameter and 0.300 mm. in length; groups of elongated cells from the inner layer of seed-coat up to 0.010 mm. in width, with characteristic beaded walls." *N. F.*

Despite the close botanical relation, the toxic principles of delphinium are not the same as those of staphisagria. Indeed the two species recognized by the N. F. differ from each other in their composition. Keller and Volker (*A. Pharm.,* 1913, ccli, 207) have found in the *D. Ajacis* two alkaloids—*ajacine,* $C_{15}H_{24}O_4N$ and *ajaconine,* $C_{17}H_{29}O_2N$. From the *D. Consolida,* Hopkins (*A. J. P.,* 1839) obtained the alkaloid which he called *calcatripine.* Keller (*A. Pharm.,* 1910, ccxlviii, 468) found in this species three alkaloids neither of which was identical with delphinine from staphisagria. For literature on the alkaloids of other species of Delphinium see Miller (*J. A. Ph. A.,* 1923, xii, 492).

Uses.—All of the larkspurs appear toxic and the indigenous *D. exaltum* and *D. azureum* are frequently fatal to sheep and cattle. As far as we know the official species have not been subjected to physiological investigation. One of the bases separated by Keller from *D. Consolida* was found to paralyze the motor nerves like delphinine (see *Staphisagria*). The *D. Consolida* was formerly used for the relief of various spasmodic disorders such as asthma, dysmenorrhea, etc., and was also attributed with diuretic powers. It is, however, at present, almost never employed as an internal remedy, being used only as a local application for the destruction of lice in the hair.

Off. Prep.—Tinctura Delphinii, *N. F.*

DEXTRINUM ALBUM. N. F.

WHITE DEXTRIN Dext. Alb.

"A mixture of soluble carbohydrates, amylodextrin, achroodextrin, erythrodextrin and maltodextrin, together with a variable amount of unconverted starch, obtained by the incomplete hydrolysis of starch by the action of an acid." *N. F.*

Dextrin; Artificial Gum; British Gum; Stärkezucker, *G.;* Dextrine, *Fr.*

The dextrins are a group of carbohydrates which may be regarded as partially hydrolized starch. In their chemical structure as well as their phyisical properties they are closely allied to the gums and mucilages, but do not yield mucic acid by the action of nitric acid. The following stages in the hydrolysis of starch by boiling with dilute acids have been recognized: (1) The starch is converted into soluble starch (some times called *amylodextrin*); this gives a blue reaction with iodine. (2) Maltose is split off leaving behind *erythrodextrin;* this gives a red color with iodine. (3) Maltose is in turn split off from the erythrodextrin forming *achroödextrin;* this gives no reaction with iodine, (4) The last named yields *maltodextrin.* (5) The final stage gives maltose as the result of complete hydrolysis. The chemical formula for the dextrines is homologous to that for starches, namely—$(C_6H_{10}O_5)n$.

Dextrin may be prepared from starch either by a torrefaction process applied to starch which has been moistened with acid and then dried, or in aqueous suspension by the action of acids or of diastase. Commercially it is usually manufactured by the Heuse Process, a torrefaction process which is as follows: One thousand kilos of starch are moistened with 2 kilos of nitric acid diluted with 300 liters of water, the mass is then made into loaves which are dried in the air, ground finely, and heated for about two hours at 100° to 120° C. The powder is then heated in a suitable oven or placed in a circular Uhland apparatus, it is heated with superheated steam, and continually stirred to secure intimate mixture. If the temperature is raised to 130° to 140° C. the duration of heating is shortened, but yellow and not white dextrin is obtained. For further detail, consult *General and Industrial Chemistry,* Molinari.

Description and Physical Properties.—"White Dextrin occurs as a white, glistening, non-hygroscopic, amorphous powder, producing a peculiar and characteristically harsh sensation when rubbed in the hand; odorless and having a sweetish taste. Only partly soluble in cold water, but completely soluble in three parts of water on boiling.

"An aqueous solution prepared in the cold and filtered is colored wine-red by iodine T.S.; an aqueous solution prepared with boiling water is colored blue by iodine T.S. Alkaline cupric tartrate solution is not changed by a solution of White Dextrin in the cold, but is reduced on boiling.

"Separate portions of a freshly prepared, filtered solution in cold water do not become turbid on the addition of calcium chloride T.S., or of calcium hydroxide T.S. (*oxalic acid*). Not more than 5 per cent. of White Dextrin is soluble in boiling alcohol (*dextrose*). Dry White Dextrin at 110° C.: it loses not more than 10 per cent. in weight (*moisture*). Separate portions of a filtered aqueous solution of White Dextrin (1 in 20) are not immediately precipitated by lead acetate T.S., or by basic lead acetate T.S., but upon the addition of a few drops of ammonia water to the mixtures, precipitation occurs (difference from *natural gums*). A solution of White Dextrin does not darken on the addition of hydrogen sulphide T.S. even when supersaturated with ammonia water (*metals*). White Dextrin yields not more than 0.5 per cent. of ash." *N. F.*

Dextrin is used in medicine solely for its pharmaceutical properties, occasionally as an emulsifying agent, more frequently to give consistency to medicinal pastes.

Off. Prep.—Pasta Dextrinata, *N. F.*

DEXTROSUM. U. S.

DEXTROSE Dextros. [d-glucose]

"A sugar [$C_6H_{12}O_6.H_2O$] usually obtained by the hydrolysis of starch." *U. S.*

Anhydrous Glucose; Pure Glucose; Saccharum Amylaceum.

Anhydrous dextrose is prepared from granular hydrated glucose (dextrose), which is produced in a manner similar to that employed for the preparation of syrupy glucose (see *Glucosum*), the conversion being carried to completion and the dextrose crystallized by reducing the temperature, adding previously formed dextrose crystals, and centrifuging the granular crystalline mass which results, to remove dextrin and other impurities. The details are as follows: *Cerealose,* the crude crystalline product obtained by the complete hydrolysis of starch, is mixed in a kneading machine with enough water to enable it to be centrifuged. Washing with cold water in this manner raises the purity to 99 per cent. The partly purified product is then heated with water to make a solution of sp. gr. 63° to 68° Brix, and is filtered through bone black filters at a high temperature (about 80° C.). The syrup is then crystallized for 72 hours without seeding. The crystalline residue is then centrifuged, and washed with cold water and subsequently dried in a hot air drier at 40° to 50° C. to constant weight. In this manner a purity of 99.9 per cent. has been reached and the article contains no bleaching agents or chemicals. (*J. I. E. C.,* 1922, xiv, 217.)

Description and Physical Properties.—"A white, crystalline powder, or white granules. It is odorless, and has a sweet taste. One Gm. of Dextrose is soluble in 1 cc. of water, and in 59 cc. of alcohol, at 25° C. It is more soluble in boiling water and in boiling alcohol.

"An aqueous solution of Dextrose (1 in 20) is neutral to litmus paper and is dextrorotatory. The specific rotation $[a]_D$ of Dextrose determined at 25° C. in an aqueous solution containing in each 100 cc. 10 Gm. of Dextrose, previously dried to constant weight at 100° C., and using a 200 mm. tube, is not less than $+52.5°$ and not more than $+53.0°$. The solution must be allowed to stand twenty-four hours before observing the rotation. Add a few drops of its aqueous solution (1 in 20) to 5 cc. of hot alkaline cupric tartrate T.S.: a copious red precipitate of cuprous oxide is formed (*difference from sucrose*).

"Dextrose loses not more than 10 per cent. when dried to constant weight at 105° C. Ash: not more than 0.1 per cent. One Gm. of finely powdered Dextrose dissolves completely on boiling with 15 cc. of alcohol under a reflux condenser (*dextrin, lactose*). Add 1 drop of iodine T.S. to a solution of 1 Gm. of Dextrose in 10 cc. of distilled water: the liquid is colored yellow (*soluble starch, sulphite*). Its aqueous solution (1 in 20) meets the requirements of the test for *heavy metals.* Dissolve 1.5 Gm. of Dextrose in 5 cc. of distilled water, add 5 cc. of diluted sulphuric acid and 1 cc. of bromine T.S., and heat for five minutes on a water bath. Add 0.5 Gm. of potassium iodide, follow with 5 drops of stannous chloride T.S., cool, and test for *arsenic.* The stain produced, if any, is not greater than that produced in a test made with the same quantitites of reagents and 2 cc. of the standard arsenic solution. Two Gm. portions of Dextrose show no more *chloride* than 0.5 cc. of fiftieth-normal hydrochloric acid, and no more *sulphate* than 0.5 cc. of fiftieth-normal sulphuric acid.

"Preserve in well-closed containers." *U. S.*

It melts at 146° C., and at higher temperatures decomposes with the production of caramel. Nitric acid oxidizes it and forms a number of decomposition products of which *saccharic acid.* $H_2C_6H_8O_8$, is the most important. Saccharic acid is an amorphous, deliquescent solid easily soluble in water and forming salts with metallic bases. Dextrose has strong reducing properties and is estimated quantitatively by means of Fehling's solution.

Uses.—It is generally held by physiologists of to-day that all carbohydrates are converted into dextrose before they are utilized by the body cells. There is reason to believe that increasing the amount of this sugar in the blood, thereby offering to the working muscle readily-oxidizable, energy-yielding form of carbon, not only increases its immediate efficiency but lessens the call upon the fuel stored up with it. It is to this mechanism and the rapidity of its absorption that sugar owes its power of banishing the sense of fatigue from muscular exertion. Thus Dixon (*J. P.,* 1907, xxxv, p. 346) has found that the injection of glucose into the blood stream may cause an immediate increase in the force of the cardiac contractions presumably by furnishing an easily oxidizable food.

Kleiner (*J. Ex. M.,* April, 1916) has found that after the intravenous injection of large amounts of dextrose in dogs, the blood sugar returns to its normal quantity within 1½ hours. Of the excess dextrose introduced, the major part is eliminated through the kidneys but about 40 per cent. escapes from the blood vessels, by the process of dialysis, into the surrounding tissues and a small amount is destroyed by increased oxidation. It has long been known that in conditions where there is an inability to oxidize blood sugar, as in diabetes mellitus, there is a tendency towards the diminution of the alkalinity of the blood; a condition known commonly although inaccurately as acidosis. There is strong evidence that a similar disturbance occurs when there is a deficiency in the food supply, especially of the carbohydrate foods. Conversely flooding the system with excess of sugar in cases of acidosis, even when the result of diabetes, will usually—at least temporarily—ameliorate this condition.

Chemically pure dextrose has been introduced into medicine in order to provide a form of sugar suitable for intravenous administration.

Buedingen (*D. A. K. M.*, 1914, cxiv, 534), Pfalz (*D. M. W.*, 1919, xlv, 1181) and others have injected intravenously a dextrose solution, isotonic with the blood, in the treatment of *heart disease* with asserted benefit. Litchfield (*J. A. M. A.*, 1918, lxxi, 503) introduced the use of dextrose intravenously in the treatment of *pneumonia.* In his earlier cases he employed an isotonic solution, but later much more concentrated solution, as high as 25 per cent. Of this solution 250 cc. (8½ fluidounces) is injected very slowly into the vein so that upwards of an hour is required for the complete dose. This method has been followed, more or less modified in details, by John (*A. J. M. S.*, 1920, clx, 542) and others with apparently satisfactory results. Fisher and Snell (*J. A. M. A.*, 1924, lxxxiii, p. 1906) report prompt relief of the symptoms of surgical *shock* by the conjoint administration intravenously of dextrose and insulin. They used 1000 cc. of a 10 per cent. solution of glucose, with a simultaneous administration of 30 units of U-20 insulin. Titus and Givens (*J. A. M. A.*, 1922, lxxviii, 92) employed glucose intravenously in pernicious *vomiting of pregnancy* and also in *eclampsia,* on the theory that these toxemias were due to a carbohydrate deficiency; they report an immediate clinical improvement in individual patients and a general lowering of the mortality rate.

For intravenous use it is essential that the dextrose shall be of the highest purity. Titus and Givens find that even with the best quality of dextrose it is advisable to filter the solutions because of the presence of dust particles. It is, of course, also essential that the solutions should be completely sterilized, which may be accomplished by heating in the autoclave, under 15 pounds' pressure, for 30 minutes. In a number of cases unpleasant symptoms have been caused apparently from the acidity of the solution. Williams and Swett (*J. A. M. A.*, 1922, lxxviii, 1024) find that heating solutions of glucose increases the hydrogen ion concentration —that is the acidity—and recommend, for the purpose of counteracting this, the addition of a " buffer " salt composed of a mixture of monopotassium and dipotassium phosphate. The solutions of dextrose employed have ranged in concentration from 5.1 per cent., which is isotonic with the blood, up to 25 per cent. The solutions may be made directly in distilled water, the addition of sodium chloride being unnecessary with these concentrations.

DIAMORPHINÆ HYDROCHLORIDUM. Br.

DIAMORPHINE HYDROCHLORIDE

" Diamorphine Hydrochloride, $C_{21}H_{23}NO_5$,-HCl,H_2O, is the hydrochloride of an alkaloid obtainable by the action of acetic anhydride on morphine." *Br.*

Diacetylmorphinæ Hydrochloridum, *U. S. IX; Hydrochloridum, Br.;* Diacetylmorphine Hydrochloride; Heroin Hydrochloride; Diacetylmorphinum Hydrochloridum, *P.G.*

Because of a Federal law forbidding its importation or manufacture in this country, this alkaloid has been dropped from the U. S. Pharmacopœia. It was introduced under the trade-name of *Heroin.* It is made by treating morphine with acetyl chloride, washing the product with a dilute alkaline solution and crystallizing from alcoholic solution. The base, diamorphine, is " a white, crystalline powder without odor. One Gm. of Diacetylmorphine dissolves in about 1700 cc. of water, 31 cc. of alcohol, 1.4 cc. of chloroform, and in 100 cc. of ether at 25° C. Its saturated alcoholic solution is alkaline to moistened litmus paper. It melts between 171.5° and 173.5° C. Dissolve about 0.01 Gm. of Diacetylmorphine in a few drops of nitric acid; a yellow color is produced, which gradually changes to greenish-blue. Heat about 0.1 Gm. of Diacetyl-morphine with 1 cc. of alcohol and 1 cc. of sulphuric acid; ethyl acetate is produced, recognizable by its odor." *U. S. VIII.*

For further details of the properties of this base see *U. S. D.*, 20th ed., p. 401.

The hydrochloride is a " white, crystalline powder; taste bitter. Melting point from 231° to 232° C. Soluble in 3 parts of *water* and in 11 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of chlorides. 0.1 gramme dissolved in 2 millilitres of *alcohol* (90 per cent.), mixed with 1 millilitre of *sulphuric acid* and warmed, develops an odor of acetic ether. A solution of 0.1 gramme in 1 millilitre of *sulphuric acid* heated on a water bath, cooled and diluted with 6 millilitres of *water,* gives a deep blue color on the addition of an aqueous solution (0.5 in 100) of *potassium ferricyanide* to which 1 drop of *T. Sol. of ferric chloride* has been added. Treated with a few drops of *nitric acid* a yellow color is produced, which changes to greenish-blue on warming, and finally becomes yellow again. 0.02 gramme added to 5 millilitres of an aqueous solution (0.5 in 100) of *potassium ferricyanide,* to which 1 drop of *T. Sol. of ferric chloride* has been added, produces a greenish color and not a deep blue (absence of morphine)." *Br.*

A method for the rapid determination of small quantities of heroin or its salts, especially adapted for revenue officers who are required to give testimony concerning seizures under the Harrison Narcotic Act, was devised by Reginald Miller and is described in *A. J. P.*, 1915, p. 248. It is a colorimetric method, using the formaldehyde sulphuric acid reagent. Duran (*J. A. Ph. A.*, 1916, p. 163) makes use of the insolubility of morphine in carbon tetrachloride to separate the two bases.

Uses.—In its general physiological action diamorphine acts much like morphine except that, according to Ott, it is depressant to the spinal cord. It is, however, about twice as powerful in its depressant action upon the respiratory center. For this reason it is greatly inferior to morphine as an analgesic. Its most important use in medicine is as a sedative to the respiratory center; thus it is employed to allay *cough* whether due to *bronchitis* or of nervous origin, to relax the *asthmatic* paroxysm, in *whooping cough, cardiac dyspnea,* and similar conditions. According to Impens (*A. G. P.*, 1899, lxviii, p. 527), although actually more poisonous to the respiratory center, it is relatively safer than morphine as disproportionally smaller quantities are needed to exercise therapeutic sedation.

Diamorphine has been employed by physicians in cases in which formation of the drug habit is feared but it is fully as dangerous a drug in this regard as morphine itself, indeed, the heroin habit is apparently the more rebellious addition of the two. Cases of acute poisoning are not very numerous but Trawick (*Kentucky Med. Journ.*, 1911) reports a case, following a dose of one-half a grain, with serious symptoms of the opium type—marked slowing of the respiration, and contracted pupils. In some cases there is also a semi-delirious condition somewhat resembling that seen in scopolamine poisoning.

Dose, one-sixteenth to one-sixth of a grain (0.004–0.01 Gm.).

DICHLORAMINA. U. S.

DICHLORAMINE Dichloram. [Paratoluenesulphondichloramide, Dichloramine-T]

" Dichloramine [$C_6H_4(CH_3)(SO_2NCl_2)$] contains not less than 28 per cent. and not more than 30 per cent. of active chlorine." *U. S.*

This is the acid of which chloramine is the sodium salt. It differs from its sodium salt in that it is soluble in certain organic bases, notably, eucalyptol and liquid petrolatum, although insoluble in water.

When perfectly pure, dichloramine keeps unchanged but commercial varieties decompose with a rapidity in proportion to the amounts of impurities present, solutions in chlorcosane show a noticeable diminution in strength within a month. Sollmann (*J. A. M. A.*, 1919, lxxii, 992) determined the rate of destruction of dichloramine by various forms of petrolatum. With liquid petrolatum from 25 to 50 per cent. of the dichloramine was decomposed in one day and 71 per cent. decomposed in two months. With various ointment petrolatums from 80 to 95 per cent. was decomposed in one day. With chlorcosane the loss in strength was about 10 per cent. in one day and about 25 per cent. in one week. The destruction by these ointments was practically the same for the white as for the yellow. Kerosene and olive oil decomposed dichloramine with extraordinary rapidity. Solutions in carbon tetrachloride were practically stable for a week and at the end of two months showed loss of only 21 per cent.

It is prepared by the following method: Chlorinated lime (from 350 to 400 Gm.) of good quality is shaken with 2 liters of water on a shaker for half an hour, and then the mixture allowed to settle. The supernatant fluid is siphoned off and the remainder filtered. Powdered toluene-parasulphonamid, 75 Gm. (the crude product may be used), is then added to the hypochlorite solution and shaken till dissolved. The mixture is filtered, if necessary, placed in a large separating funnel, and acidified by the gradual addition of acetic acid. The mixture is then extracted with chloroform; the chloroform solution, after drying over calcium chloride and filtration, is allowed to evaporate in the air. The residue is usually sufficiently pure without recrystallization.

Description and Physical Properties.—" Pale yellow crystals or a yellowish crystalline powder, having an odor of chlorine. It gradually decomposes on exposure to air, losing chlorine. Dichloramine is almost insoluble in water. It is soluble in eucalyptol and in chlorinated paraffin hydrocarbons, also in glacial acetic acid. One Gm. is soluble in about 1 cc. of benzene or chloroform and in about 2.5 cc. of carbon tetrachloride. It is decomposed by alcohol.

" Dichloramine melts at about 80° C. Add about 0.1 Gm. of Dichloramine to 5 cc. of an aqueous solution of sodium bromide (1 in 10): bromine is liberated (*difference from chloramine*). Strong mineral acids added to Dichloramine liberate chlorine. One Gm. of Dichloramine dissolves completely in 5 cc. of chloroform. Add 1 cc. of sulphuric acid to 0.1 Gm. of Dichloramine: chlorine is evolved but no appreciable darkening occurs (*readily carbonizable substances*).

"**Assay.**—Dissolve about 0.1 Gm. of Dichloramine, accurately weighed, in 20 cc. of glacial acetic acid, in a dry, glass-stoppered bottle. Add 10 cc. of potassium iodide T.S. and 50 cc. of distilled water, allow the mixture to stand for ten minutes, and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.001773 Gm. of active chlorine.

" Preserve in well-closed containers, protected from light." *U. S.*

Uses.—Dichloramine, like its near relation chloramine, is a powerful germicide. McMaster (*J. Inf. D.*, 1919, xxiv, 378) finds that the oily solution will destroy *Bacillus typhosus* in strength of five parts in 10,000, which makes it about eight times as strong as phenol when tested by the same method.

As dichloramine is practically insoluble in water, it is usually employed in the form of a solution in eucalyptol diluted with liquid petrolatum. Ordinary petrolatum has such an affinity for chlorine as to decompose the dichloramine, so that it is necessary that the solvent be saturated with this element and the Pharmacopœia therefore recognizes a chlorinated paraffine as a solvent (see *Paraffinum Chlorinatum*).

Dichloramine is used as a disinfectant. Sweet (*J. A. M. A.*, 1917, lxix, 1076) reported from a large hospital experience during the World War, that in infected *wounds* it not only gave as good surgical results as any method of treatment, but was of great practical value because of its ease of application and economy of dressing material and that it is much less irritating to the surrounding healthy skin than other disinfectants. It has also been used as an antiseptic application to the mucous membranes of the nose and throat and even of the eye. As a surgical disinfectant it may be employed in strengths of from 2 to 10 per cent. As an application to the mucous membranes from 0.5 to 2 per cent.

Horan (*Illinois M. J.*, 1921, xl, 123) finds dichloramine dressings of great value in *burns* because the oily solvent makes the changing of dressings painless while they are actively antiseptic. Dakin and Dunham (*B. M. J.*, May 20, 1917) have introduced also, under the name of *Halazone,* the para-sulphone dichloramide-benzoic acid, which is intended for the sterilization of drinking water.

DIGITALIS. U. S. (Br.)

DIGITALIS Digit. [Foxglove, Digitalis Folium P. I.]

"Digitalis is the dried leaf of *Digitalis purpurea* Linné (Fam. *Scrophulariaceæ*). Digitalis, in the form of the tincture, properly diluted and injected into the ventral lymph sac of a frog, has a mimimum systolic dose (the minimum dose producing in one hour a stoppage of the ventricle of the heart in systole) not exceeding 0.006 cc. of tincture, equivalent to 0.00,000,05 Gm. of ouabain, for each gram of body weight of frog. It contains not more than 2 per cent. of browned leaves, stems, flowers, or foreign organic matter, and yields not more than 5 per cent. of acid-insoluble ash." *U. S.*

"Digitalis Leaves are the dried leaves of Digitalis purpurea, *Linn.*, collected from plants commencing to flower, thoroughly dried at a low temperature, and kept dry in well-filled air-tight containers. When powdered no portion should be rejected." *Br.*

Digitalis Folia, *Br.*, Digitalis Leaf; Digitalis Leaves, Foxglove Leaves; Fairy Cap, Fingers, Thimbles, or Bells, Lady's Glove, Purple Foxglove, Flop-dock, Throatwort, Cottagers; Digitale, *Fr. Cod.;* Feuilles de Digitale Pourprée (de grande Digitale), Digitale Pourprée, Doigtier, *Fr.;* Folia Digitalis, *P. G.;* Purpurrother Fingerhut, Fingerhutkraut, Fingerhutblätter, *G.;* Digitale, *It.;* Digital (Hoja de), Dedalera, *Sp.*

The common foxglove, *Digitalis purpurea,* is a biennial or occasionally perennial plant, native to Europe, but now widely cultivated both for medicinal and ornamental purposes in the United States and other parts of the world. It has become naturalized in several sections of the United States, particularly in Washington, Oregon and New York.

The underground portion of the plant consists of a fibrous root system which, during the first year, sends forth a rosette of long stalked, ovate to ovate-lanceolate, radical leaves. During the second summer, a single, erect downy and leafy stem arises from the center of a leaf rosette to the height of 1 to 1.5 meters and terminates in an elongated raceme of large, purple, tubular-campanulate flowers. The lower leaves are ovate to ovate-lanceolate, pointed, about eight inches in length and three in breadth, and stand upon short, winged petioles; the upper are alternate, sparse, and lanceolate; both are irregularly crenate to dentate, and have wrinkled pubescent surfaces, of which the upper is a fine deep green, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short pedicels, in such a manner as generally to hang down upon one side. At the base of each pedicel is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is gamopetalous, tubular-bell-form, swelling on the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size not unlike the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. Its mouth is guarded by long soft hairs. Externally, it is in general of a bright purple; internally, it is sprinkled with dark spots upon a white ground. There are four didynamous stamens whose filaments are white, curved, and surmounted by large yellow anthers. The style is simple, and supports a bifid stigma. The seeds are numerous, very small, grayish-brown, and contained in a pyramidal two-celled capsule.

Several varieties of *Digitalis purpurea* have occurred in cultivation, the leaves of which have been commonly collected with those of the pure species as a source of the drug of commerce. The var. *gloxinæflora* Hart. has longer racemes with larger and more spotted flowers; the var. *alba* Hart. possesses white flowers; the var. *campanulata* Hart. is a large form whose upper flowers are united into a large bell-shaped bloom; the var. *monstrosa* is a double peloric form. All of the species of the genus *Digitalis* seem to have similar effects upon the system. Miller and Baker (*J. A. Ph. A.*, March, 1914) examined 23 different species or varieties of *Digitalis* and found one or two, indeed, surpassed the *D. purpurea* in power.

The leaves of the *D. Thapsi* L. have appeared commercially under the name of *Spanish Digitalis.* Guerin states that these have practically no simple hairs and that the glandular hairs are averagely longer stalked than those of *D. purpurea.* For further details see *C. D.,* 1919, p. 1151.

Foxglove grows wild in the temperate parts of Europe, where it flowers in the middle of summer. In this country it is cultivated both for ornamental and for medicinal use. (For methods of cultivation in the United States, see Newcomb, *A. J. P.,* 1911, p. 529; Borneman, *A. J. P.,* 1912, p. 547; Miller, *A. J. P.,* 1913, p. 297.) The leaves are the part generally employed. The U. S. Pharmacopœia IX departed from the ancient requirement, and in our opinion properly so, that digitalis should be collected only in the second year. Modern investigators, such as Sharp (*P. J.*, lxxxix, 131), Miller and Baker (*J. A. Ph. A.*, 1913, ii, 198), and Carr (*A. J. P.*, 1913, lxxxv, 297) are unanimous that the first year's leaves are fully as powerful as those collected just before flowering. Hale (*Proc. A. Ph. A.*, 1910, 294), as well as Miller and Baker, finds that there is no difference between the wild and cultivated plants; indeed, the latter say, even if grown in hot houses. Likewise the formerly accepted view that digitalis leaves deteriorate rapidly has been shown to be erroneous. If properly dried, the loss of strength is practically negligible during a year's storage (Haskell and Miller, *J. A. Ph. A.*, 1914, iii, 306) and probably for several years (Pick and Wasicky, *C. D.*, 1917, lxxxix, 320); the last named authors have shown that when improperly stored the loss of potency may be quite considerable. Various methods of drying the leaves have been recommended. Joachimglu (*Ph. Wb.*, 1920, lvii, 799) recommends drying at a temperature of 60° C., while Haskell and Miller state that any temperature below 120° C. is not injurious. Pick and Wasicky recommend that the air of the container be kept dry by the use of burnt lime. Straub (*D. M. W.*, 1921, xlviii, 791) finds that, of the three chief principles of digitalis, digitalein is the most readily decomposed, digitoxin the least, and gitalin stands midway between.

The seeds contain more of the active principle than the leaves, are less likely to suffer in drying, and keep better, but are nevertheless little used. So far as the relative strength of these two parts can be determined from that of their alcoholic extracts, it would appear, from the experiments of Hirtz, that the seeds are ten times stronger than the leaves. (See *A. J. P.*, xxxiii.)

The commercial supplies of digitalis used in the United States are obtained chiefly from plants grown in Germany and the U. S. A.

Fresh digitalis leaves are without odor but acquire a characteristic odor when dried and rubbed in the hollow of the hand. The color of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green.

Description and Physical Properties.—"*Unground Digitalis.*—More or less crumpled or broken; blades ovate to ovate-lanceolate, about 25 cm. in length and contracted into a winged petiole; margin crenate or irregular; thin, lower surface densely pubescent, upper surface wrinkled, finely hairy; venation conspicuously reticulate, the midrib and principal veins broad and flat and the lower veins continued into the wings of the petiole; color of upper surface dark green, of lower surface grayish from the dense tomentose pubescence, the larger veins often purplish; odor slight when dry, peculiar and characteristic when moistened; taste very bitter.

"*Structure.*—Upper epidermis with slightly wavy vertical walls, no stomata, and numerous hairs; lower epidermis with wavy, vertical walls, numerous oval stomata and many hairs and not attached over irregular areas to the cell layer within, especially near the veins; chlorenchyma of a single layer of short palisade cells and several layers of spongy parenchyma, vascular bundles of larger veins and petiole, numerous, separated by medullary rays 1-cell wide.

"*Powdered Digitalis.*—Dark green; numerous irregular fragments of epidermis; non-glandular hairs frequently curved or crooked, up to 0.5 mm. in length, uniseriate, 2 to 8 cells, some of the cells collapsed so that the planes of adjoining cells may be at right angles, the terminal cell pointed; glandular hairs few, small, usually with a 1- or 2-celled stalk and a 1- or 2-celled head; fragments of veins and petioles with tracheæ annular, reticulate or spiral or with simple pores; calcium oxalate absent.

"**Assay.**—Prepare a tincture according to the official process and proceed as directed under *Tinctura Digitalis.*

"Preserve Digitalis, thoroughly dried, in airtight containers." *U. S.*

The British Pharmacopœia description is as follows: "Hairs of two kinds, either simple, mostly 3–5 celled and bluntly pointed, or glandular and consisting of a short pedicel bearing a unicellular or bicellular gland. In transverse section, no sclerenchymatous cells or fibers, and no crystals of calcium oxalate. In the powdered Laves, groups of epidermal cells with more or less sinuous walls, numerous fragments of multicellular hairs with thin, granular walls; but no sclerenchymatous cells or fibers, of crystals of calcium oxalate. No marked odor; taste very bitter." *Br.*

For a comprehensive description of the morphology and anatomy of the leaves of *Digitalis purpurea* and the adulterants of this drug, see Bohny's article in *Bot. Centralbl.*, 1906, p. 267. Collin reviews the pharmacognosy of Digitalis (*J. P. C.*, 1905, p. 56), showing the characteristics of the powder and the detection of the principal leaf adulterants, such as *Inula Conyza, Verbascum phlomoides, Artanthe elongata,* and *Salvia Sclarea.* Kraemer (*A. J. P.*, 1912, p. 35) discusses the morphology of digitalis leaves and shows the variation and the forms of hairs in different commercial specimens. Youngken (*J. A. Ph. A.*, 1919, p. 923) investigated the structure and pharmacodynamics of *D. Sibirica.* He found that a 10 per cent. tincture of the leaves of this Siberian herb was about 75 per cent. stronger in the physiologic effects than the U. S. P. tincture of digitalis. The chief adulterants for digitalis in recent years have been the leaves of Mullein species which may be readily detected as an admixture even in small quantities, by their candelabra-shaped trichomes and velvety texture.

Constituents.—Despite an enormous amount of labor, the chemical problems in connection with digitalis are not completely solved. While the statement made below concerning the active constituents of this drug may be revised by future investigations, we believe that it fairly represents the conclusions of the most recent and competent investigations.

It should be remarked in the first place that the term digitalin has been applied to at least four distinct substances and therefore, unless qualified, is meaningless. *Homolle's digitalin* (*French digitalin*) is an amorphous powder, probably an impure form of Kiliani's digitalin. *Nativelle's digitalin* (*digitaline cristallisée*) is apparently an impure form of the substance now known as digitoxin. *Merck's digitalin* (*German digitalin*) is a concentrated extract from the seeds; it is a yellowish-white amorphous powder soluble in either water or alcohol and contains over 50 per cent. of digitonin with 5 to 6 per cent. of Kiliani's digitalin as well as other glucosides.

The most important researches upon the chemistry of digitalis are those of Schmiedeberg (*A. E. P. P.*, 1874, iii, 19; 1882, xvi, 149), Kiliani (*A. Pharm.*, 1895, 1899; 1914, cclii), Keller (*P. J.*, July 24, 1897), Kraft (*S. W. P.*, 1911, xlix), Berry (*P. J.*, 1915, xcv, 783) and McGill (*J. Am. C. S.*, 1920, xlii, 1893).

Digitalis contains a number of glucosides; these may be divided into two groups, those that possess the characteristic physiological properties of the drug, and those whose action places them among the saponins. Of the first group there are three whose identity appears to be satisfactorily established: *digitoxin, digitalin Kiliani,* and *gitalin.* The status of *digitophyllin* is not yet settled. The saponin glucosides which do not act upon the heart include *digitonin, digitoflavone* (*luteolin*) and perhaps *gitonin.*

For account of clinical applications of various principles see under *Uses.*

DIGITONIN forms fully one-half of the mixed glucosides from the digitalis seed and the principal portion of "German digitalin," from which it may be prepared by extraction with and crystallization from 85 per cent. alcohol. Digitonin softens at 225° C., and melts completely at 235° C. The crystals dissolve sparingly in cold water, more readily in hot, to an opalescent solution which froths on agitation. It cannot be crystallized from water. The aqueous solution is lævorotatory ($[a]_D = -49$ at 25° C., and is precipitated by tannin, ammoniacal lead acetate, and baryta water. Digitonin is only slightly soluble in absolute alcohol, and still less so in ether, chloroform, or petroleum benzin. It forms a crystalline compound with amyl alcohol. According to Kiliani, digitonin has the formula $C_{27}H_{46}O_{14} + 5H_2O$, and when boiled with strong alcohol and hydrochloric acid splits up into dextrose, galactose, and *digitogenin,* the last body separating in warty masses on cooling. Digitonin does not possess the characteristic physiological properties of digitalis; its action is similar to that of the saponins.

Kraft believes that there are two substances which have been described under the name of digitonin and suggests that one of these be called *digitsaponin.* The substance described by Schmiedeberg under the name of *digitin* is probably an impure form of digitonin.

DIGITOXIN is characterized by its free solubility in alcohol and chloroform, slight solubility in ether, and insolubility in petroleum benzin. It crystallizes from alcohol in pearly scales or needles which melt at 240° C. It is quite insoluble in water, to which it does not impart even a bitter taste. Warmed with strong hydrochloric acid, it gives a yellow or greenish coloration. Schmiedeberg states that it is not a glucoside, but Kiliani asserts that upon heating its alcoholic solution with hydrochloric acid it splits up into *digitoxigenin* and a sugar, *digitoxose.* The reaction for this is now considered to be:

$$C_{34}H_{54}O_{11} + H_2O = C_{22}H_{32}O_4 + C_6H_{12}O_4$$

Digitoxin is found mainly in the leaves (Kiliani stating that it is not found in the seeds at all), but Keller (*P. J.*, July 24, 1897) finds it also in the seeds in smaller amount. It is the most poisonous of the constituents of digitalis so far isolated.

DIGITALIN (*Digitalinum verum* of Kiliani) forms a white amorphous powder or soft white grains which remain unchanged when heated to 200° C., at 210° C. begin to aggregate, and towards 217° C. melt, becoming yellow. When treated with water the particles of digitalin swell up and dissolve slightly, giving a solution which foams strongly on agitation. It is dissolved sparingly (1 to 100) by cold proof spirit, but in considerable amount by hot rectified spirit or absolute alcohol. When a minimum of alcohol is used, the solution on cooling becomes almost solid from the separation of a thick magma of granules, which are, however, destitute of crystalline structure. This peculiar behavior affords a valuable means of testing its purity, as only a small percentage of the other glucosides with the digitalin prevents the formation of the granules. The minutest admixture of amorphous glucosides also rapidly causes an intense yellow coloration. Digitalin is very sparingly soluble in ether or chloroform. When digitalin is heated with diluted hydrochloric acid, an insoluble resinous substance almost immediately separates out; Schmiedeberg termed this *digitaliresin.* By operating in alcoholic solution, Kiliani avoids the separation of resin, and finds that digitalin splits up as a glucoside into *digitaligenin, glucose,* and *digitalose,* thus:

$$C_{29}H_{46}O_{12} + H_2O = C_{16}H_{22}O_2 + C_6H_{12}O_6 + C_7H_{14}O_5$$

Kiliani found that commercial *digitalinum purum* contained but 5.5 per cent. of true digitalin.

GITALIN has been described by Kraft (*S. W. P.*, 1911, xlix) as an amorphous white powder soluble in 600 parts of water. It can be obtained also as a crystalline hydrate. *Digitalein* of Schmeideberg is regarded by Kraft as an impure gitalin. Kiliani doubts the chemical individuality of gitalin. There is on the market a substance called *verodigen* which is asserted to be gitalin.

Digitalis contains, besides active principles, a volatile oil, a fatty matter, a red coloring substance analogous to extractive, chlorophyll, albumen, starch, sugar, gum, lignin, and salts of potassium and lime, among which, according to Rein and Haase, is acid potassium oxalate. Morin, of Geneva, discovered in the leaves two acids: one fixed, called *digitalic acid,* the other volatile and resembling valerianic acid, which he proposed to name *antirrhinic acid* (*P. J.,* vii, 294). England (*A. J. P.,* 1892, 361) found about 5 per cent. of fixed oil in digitalis leaves. Morries obtained a narcotic empyreumatic oil by the destructive distillation of the leaves. The yield of ash from digitalis leaves is usually put down at from 7 to 10 per cent., and this is in accord with the result reached by F. H. Alcot with British leaves. (*P. J.,* Jan., 1903.) On the other hand, M. Greshoff (*P. J.,* Dec., 1902) has obtained in various samples of German digitalis, after the leaves have been freed from sand and the leaf-stalks removed, a yield of from 16.4 to 25 per cent. of ash.

Assay.—The three animals most commonly used as reagents for the biological standardization of digitalis are the frog, the guinea-pig, and the cat. Although a number of writers had employed physiological tests to determine the relative potency of different digitalis bodies, the first to use the biological assay in a systematic manner was Houghton, who used what is now known as the "twelve hour frog method."

The U. S. P. IX gave an optional biological standard for digitalis based upon the so-called one hour frog method. The same test has been made compulsory in the U. S. X (for official description see under *Tinctura Digitalis*). In the second part of the U. S. P. IX this method was described somewhat more in detail than it is in the present Pharmacopœia. As this description contains much that is of practical interest, it is here repeated: "For the members of the digitalis series the so-called 'one hour frog' method is recommended. This method consists essentially in ascertaining the dose of a drug or preparation which will bring the heart of a standard sized frog to systolic standstill in one hour's time. The method is carried out as described below; all measurements being performed with the same degree of accuracy used in ordinary quantitative chemical estimations.

"*Frogs.*—The frogs to be employed in an assay should be in a healthy condition and of the same species. Those most commonly obtainable in this country are the common grass frogs (*Rana viridis* or *Rana pipiens*). While the dose for a frog is estimated according to its weight, it is best to use frogs of a fairly uniform size, the most convenient weight for such work being between 15 and 25 Gm.

"*Storage.*—Before use the frogs should be stored in tanks kept in a cool room, preferably where the temperature does not rise above 15° C. The bottom of the tanks should be covered with running water or, if running water is not convenient, standing water may be used if it is changed from two to four times daily. An hour before the frogs are to be used for an assay a sufficient number should be taken to the operating room, each one carefully weighed to within 0.1 Gm. [0.5 Gm. *U. S. X*] and placed in an individual wire cage or container, these are then placed in a tank containing water to the depth of about 1 cm. (½ inch), which is kept during the process of assay at a uniform temperature of 20° C. The maintaining of a uniform temperature at which all assays of the members of this group should be carried out is important, as the susceptibility of frogs differs very considerably at different temperatures.

"*Dosage.*—After the frogs have been weighed as described, the doses to be given are calculated according to their weights and are measured into small conical glasses by means of a finely graduated pipette. The doses of the preparation which are to be injected should be as uniform in quantity as possible and should not exceed 0.015 mil for each gramme of body weight of frog. The members of the digitalis series may be assayed in either fluidextract or tincture strength, being diluted with water as may be necessary to get the volume dose. In case the alcohol content in any preparation after dilution is higher than 20 per cent., the preparation may be subject to careful evaporation and subsequent dilution with an aqueous solution containing 0.7 per cent. of sodium chloride until the original volume is restored and the alcohol content is not above the per cent. named. It is always best to have the alcohol content of different preparations uniform. In case there is a precipitate the preparation to be assayed should be shaken each time a dose is measured out. When the doses are ready, they may be injected into the anterior lymph sac of the animal. This is done by means of a glass pipette which is drawn out to a fine point [the so-called 'tuberculin' hypodermic syringe, which is graduated in 0.01 cc., is more convenient]. The frog is held on its back in one hand and the pipette with the contained drug in the other, the mouth of the frog is opened with the point of the pipette and, carefully avoiding the tongue, the floor of the mouth is punctured and the point of the pipette is then seen to enter the anterior lymph sac of the frog. The contents of the pipette are now forced into the sac either by gravity or by gently blowing, if necessary. In the latter case, care should be taken not to introduce air into the sac. Care should also be taken not to puncture the skin. The animal is then replaced in its cage in the tank, the temperature of which is maintained as stated at 20° C. At the end of one hour from the time of injection each frog is pithed, both brain and cord, the heart is exposed and its condition examined. For the correct end reaction the ventricle should be in systolic standstill while the auricles should be widely dilated. Following mechanical stimulation feeble contractions may be allowed in the auricles and localized contractions in the ventricle, but no general contraction is allowable. If when the heart of an animal is being exposed for examination, remains of the injected drug are found in the lymph sac unabsorbed, such an animal should be discarded and not considered in the results obtained. It happens sometimes that one frog out of a large series may prove a decided exception to the others in the way of increased or decreased susceptibility to the drug. Such an animal should also be discarded. After the primary or trial assay has been carried out and the approximate strength of the preparation ascertained, a second series of frogs is injected in like manner, using doses the limits of which are considerably narrower than the first series. A third or even fourth series of injections may be necessary to confirm the earlier results. The dose thus found is then compared with the dose of a standard which is similarly ascertained upon another series of frogs of the same lot. From such a comparison the strength of the unknown preparation can be suitably adjusted. The use of a standard is made necessary by the fact that frogs differ in their susceptibility to the members of the digitalis series at different seasons of the year. The condition of susceptibility is ascertained and allowed for by the use of a solution of ouabain (see Part III) as a standard which in appropriate doses is injected into a series of frogs and their resistance thus determined." *U. S. IX.* The necessary strength of an unknown preparation may be calculated from the dose actually found by the ratio of the standard dose of ouabain to the dose of ouabain found necessary to kill. Thus:

"Standard dose of ouabain : Found dose of ouabain :: Standard dose of drug being assayed : Necessary dose of unknown.

"The standard dose of ouabain is 0.0000005 Gm. per gramme of body weight of frog. The standard dose of Tincture of Digitalis to correspond is 0.006 mil per gramme of body weight of frog. If, therefore, in a certain series of frogs the resistance to ouabain is found to be increased so that a dose of 0.00000075 Gm. is necessary to stop the heart in systole in one hour, the dose of Tincture of Digitalis would also have to be increased to 0.009 mil, and the actual dose found calculated against this, instead of against the standard dose of 0.006 mil. For example, in frogs showing the increased resistance as indicated above, if the Tincture being examined assays 0.018 mil per gramme of body weight it is one-half strength." *U. S. IX.*

In carrying out this method it is well to make a preliminary series of observations on 5 or 6 frogs, using doses rising in equal gradations from 0.2 to 1.0 milligrammes of the digitalis per gramme of frog. At the same time a similar series of frogs should be tested with ouabain solution, using doses ranging between 0.0003 to 0.0007 milligramme per Gm. The ouabain may conveniently be made up into a solution containing 5 parts per 100,000; of such a solution 0.01 cc. would represent the standard dose per gramme of frog-weight for ordinarily susceptible frogs. In standardizing frogs the doses for a 25-gramme frog of such a solution would be from 0.2 to 0.5 cc. for the preliminary series. A second set of experiments is then performed using as the limit of doses the largest amount which failed to arrest the heart and the smallest amount which caused cardiac spasm and using two frogs for each of the doses in the middle. Houghton prefers that the observation be made at the end of 14 or 15 hours, instead of one hour. Focke (*A. Pharm.*, 1907) modifies the frog's heart method by using a constant dose, the time of arrest being the variant which furnishes the index to relative potency.

The "guinea-pig method" consists in simply finding the minimum lethal dose for a guinea-pig. To a series of previously weighed guinea-pigs is administered hypodermically ascending doses of a tincture of the sample to be tested. The end-point of the test is the smallest dose which will kill the guinea-pig within twenty-four hours. The method is essentially similar to that employed for aconite. (See *Aconitum.*)

A much more elaborate method has been suggested by Hatcher (*J. A. M. A.*, 1910, lv, p. 746). He has found that the lethal dose of crystalline strophanthin (ouabain) for the cat is very constant, being almost exactly 0.1 milligramme per kilogramme of body weight when administered intravenously. The method of assay is to give a quantity of the sample to be tested, of about two-thirds of the expected fatal dose for the cat, and then run slowly into a vein a solution of strophanthin until death is caused. The difference between the ordinary fatal dose of the glucoside and the quantity used in the test represents the amount of strophanthin to which the digitalis being tested is equivalent; that is, the larger the amount of strophanthin which has been used, the weaker is the preparation. Other test-animals which have been suggested are gold-fish (Pittenger) and turtles (Zeigler, *J. A. Ph. A.*, 1916, v, 1188).

Among the most important objections to the frog methods of standardizing are the facts that not only is there great difference in susceptibility between different species of frogs, but also in the same species at different seasons of the year. Focke, for instance, has found that the frog in the spring was twice as resistant to digitalis as in the fall. (*A. Pharm.*, 1907.) This variation is due in part to the difference in temperature at various seasons of the year but also in part to the nutritional condition of the batrachian. For this reason the U. S. P. recommends that the frogs be standardized by testing their resistance against crystalline strophanthin. It is doubtful, however, whether this standardization of a frog is of any great usefulness for the reason that the relative toxicity of various members of the digitalis series to the cold-blooded animal bears little correspondence to their relative power in man. The question of whether or not the guinea-pigs show seasonal variation in susceptibility to digitalis is still open for difference of opinion. See Haskell (*A. J. P.*, 1914, lxxvi, p. 7).

There has been a good deal of difference of opinion as to which one of the methods of assay is to be preferred. Colson (*J. A. Ph. A.*, 1918, vii, 13) prefers the cat method as being more accurate and less time consuming; Kruse (*J. P. Ex. T.*, 1923, xxi, 216), on the other hand, condemns the intravenous injection, as the factor of rapidity of absorption influences clinical activity. It should be noted that, as shown by Rowe (*J. A. Ph. A.*, 1919, viii, 900), there is no close relation between the results on different animals. Gottlieb (*A. E. P. P.*, 1918, lxxxiii, 117) pointed out that there will be a difference in the one-hour and twelve-hour frog methods, depending on the variations in rapidity and elimination of the various principles; thus sample A by the one-hour method might be more active than sample B, but by the twelve-hour method the relationship be reversed.

After all none of these methods of biological standardization of digitalis and its congeners can be regarded as an accurate method for the assay in the same sense that chemical standardization is; their chief utility is in preventing inert preparations of digitalis from being placed upon the market. In a comparative test by a number of experienced pharmacologists carried out under the auspices of a committee of the American Drug Manufacturers' Association, neither the Hatcher's method on the cat nor the one-hour frog test gave satisfactory results; not only was there wide variance in the results by different workers, but the results did not correspond with the known values of the tinctures tested.

For a discussion of the various details of the methods for the assay of digitalis, see also Edmunds and Hale (*U. S. Hygienic Laboratory Bulletin* No. 48, 1909); Hamilton and Rowe (*J. A. Ph. A.*, 1915, iv, p. 108); Vanderkleed and Pittenger (*J. A. Ph. A.*, 1914, iii, 815).

No simple and satisfactory *chemical assay* process has yet been devised for digitalis and hence the U. S. P. contains no process. The amount of digitoxin present in digitalis has been proposed by several investigators as a means of standardizing it, but it is by no means clear that this is a reliable criterion. Several attempts have been made to estimate the practical usefulness of the assay for digitoxin by comparing the results with the physiological tests of digitalis. While some experimenters have found a fairly close agreement between them, the great majority of those who have studied the question incline to the opinion that the two methods of assay do not run at all parallel. There are three possible reasons for this variation and each one of them seems to be operative. These are, first, inaccuracies in the chemical method for assaying digitalis; second, the unavoidable inaccuracy of the biological assay; third the fact that the relative quantity of digitoxin to the other constituents of digitalis may vary from one sample to another. While digitoxin is the most important constituent of digitalis it is by no means the only important one. The experiments of Lutzkaga (*A. I. P. T.*, 1908, xviii) and those of Barger and Shaw demonstrate that between 60 and 70 per cent. of the activity of digitalis leaf is due to its digitoxin, and that the proportion in digitalis cannot be relied upon as a criterion of the quality of the drug. (See *B. Chem. G.*, 1897; *Ph. Rev.*, 1901, 514; *D. C.*, 1902, 223; *P. J.*, 1902, 358; *Chem. News*, 1903, 123; *A. Pharm.*, 1903, 358.) J. Gordon Sharp proposed a test for digitalis based upon the fact that the leaves contain an enzyme, which acts on amygdalin producing an odor like that of bitter almond with hydrocyanic acid. (*P. J.*, 1902, 236.)

Knudson and Dresbach (*J. P. Ex. T.*, 1922, xx, p. 205) report on quantitative assay of digitalis based upon the *Baljet reaction* (*Schweiz. Ap. Ztg.*, 1918, lvi, p. 84). This is an orange-red color produced by the salts of picric acid with digitalis and strophanthus glucosides. The quantitative method as applied by the authors is as follows: A quantity of the liquid preparation, representing 0.5 Gm. of digitalis, diluted with water to 15 cc. To this add 2.5 cc. of a 10 per cent. solution of neutral lead acetate. After standing one minute filter and to 12.5 cc. of the filtrate add 1.25 cc. of a 10 per cent. solution of dibasic sodium phosphate. Add water up to 25 cc. Filter. The filtrate should be clear and almost colorless. Take 5 cc. of this filtrate and add to it 5 cc. of picrate solution, at the same time using for standard a solution of ouabain containing 0.266 milligm. in 5 cc. of water. These two solutions are allowed to stand 20 minutes and then compared in a colorimeter. Instead of the ouabain solution a permanent standard made with potassium dichromate can be used. In camparative experiments with 25 galenical preparations by this color reaction and the Hatcher cat assay, there was a very obvious similarity in the results by the two methods; in two preparations, however, there was considerable discrepancy.

Uses.—Although digitalis appears to have been used by the inhabitants of Britain as far back as the tenth century of the Christian Era, it was introduced into regular medical practice by William Withering in 1775, who obtained his knowledge of the value of foxglove in dropsy from an old woman of Shropshire.

The opinion of the medical profession as to the mode of action of digitalis and the class of cases in which it is useful has undergone many changes. Recent studies have led to another one of these revisions of the accepted belief concerning the effects of this drug upon the system, especially upon the circulation.

When given in small dose, that is, in quantities barely sufficient to cause any visible change, the only marked effect of digitalis upon the circulation is a slowing of the pulse, which is due to a stimulation of the inhibitory mechanism of the heart. After somewhat larger quantities the heart-beat becomes extremely slow, the size of the wave very large, and the vigor of the contraction of the heart perhaps a little increased, but the blood pressure is not materially affected because of the great reduction in pulse rate. The slowing of the pulse is due partly to a delayed conduction of the cardiac muscles, but also in part to a reduction in the impulses arising in the node. In the normal animal these effects are apparently produced entirely through the inhibitory mechanism unless toxic doses have been given. According to Cushny (*J. P. Ex. T.*, 1918, xi, 103), however, when the nutritional condition of the heart muscles is poor, as seen in certain cardiac diseases, conduction across the auriculo-ventricular bundle may be greatly impeded or entirely blocked through an action directly upon the muscle tissue.

Despite the fact that there is no increase in arterial pressure it is probable that even at this stage of the action of the drug there is more or less stimulant effect upon the vasomotor mechanism, the pressor effect of the vascular constriction being overcome by the great reduction in the pulse rate. When toxic doses are administered the blood pressure is distinctly, and sometimes greatly, elevated. This is brought about partially by an increased vigor of the heart's contraction, but probably in greatest part by constriction of the blood vessels. Often at this stage there appear various forms of cardiac irregularities, the most common of which is that which is known as an "extra-systole"; the irritability of the heart muscle is so greatly increased that before the completion of the diastolic period a new contraction interrupts the relaxation. Sometimes these extra-systoles occur regularly with every alternate beat of the pulse, producing the so-called *pulsus bigeminus* (sometimes incorrectly called a dicrotic pulse). Later on in the poisoning the cardiac contractions become extremely rapid, more or less irregular, and the diastole never complete. Eventually in the frog the ventricle passes into a condition of permanent contraction, or, as it is more frequently called, systolic spasm. In the warm-blooded animal, however, the heart relaxes immediately before death and passes into a state of fibrillation.

Under certain conditions digitalis produces a marked increase in the flow of urine. Apparently in normal health it has little or no diuretic action. Its effect upon the kidney appears to be the result of the reaction of the renal artery. Joseph (*A. E. P. P.*, 1913, lxxiii, p. 81) has shown that the contraction of the renal artery by digitalis is less than that in the rest of the body and that after small doses there may even be an actual dilation of the blood vessels of the kidney. This, of course, means that a larger proportion of the blood is driven to these organs and consequently there will be a freer secretion. Although both Gottlieb (*A. E. P. P.*, 1917, lxxxii, p. 1) and Hatcher and Eggleston (*J. P. Ex. T.*, 1919, xii, 405) have found 90 per cent. of digitalis glucoside, injected intravenously, disappear from the blood within ten to fifteen minutes, the physiological effects of digitalis last for a long period of time. Robinson (*J. A. M. A.*, 1919, lxxiii, 716) states that the maximum effects from a single dose of digitalis by the mouth appear within from 15 to 26 hours and last for several days, the average of his observations being nine days; but Pardee (*J. A. M. A.*, 1920, lxxv, 1258) finds the effect of single doses begins in 3 to 4 hours and reach their maximum usually by the 6th or 7th hour. The average elimination under continuous administration ordinarily is about 22 minims of the tincture per day, and the continued administration of 10 minims three times per day if continued will generally lead eventually to toxic symptoms.

Digitalis is used in practical medicine for three purposes, as a stimulant in acute circulatory failure, as a diuretic, and as a cardiac tonic in chronic heart disease.

As a circulatory stimulant digitalis is a remedy of only secondary importance. In the first place, in the acuter forms of *circulatory failure*, such as *surgical shock*, when given by the mouth it is so slow in its action that the condition will have terminated one way or the other before it begins to influence the circulation. When given hypodermically it is intensely irritant and even by this channel its effects are too slow to be of much service, and although certain proprietary preparations are upon the market which are suitable for intravenous injection, there is no reason to believe them superior for this purpose to stophanthin. In *infectious fevers* the weakness of the heart manifests itself sufficiently gradually that there is usually time enough for the action of the drug, but unfortunately clinical experience has shown that in this condition its power is much diminished.

As a diuretic digitalis is of service whenever there is *dropsical accumulation*. How far the beneficial effects are the result of improvement in the circulation and how far from a direct action upon the kidney is somewhat doubtful.

The most important use of this drug is in the treatment of various forms of *chronic heart disease*, including those due to *valvular lesions*, various types of *myocarditis*, and the *cardiac neuroses*. Its beneficial influence in these states is probably the result of several factors: the stimulation of inhibition gives the heart more time to rest, the increased force of the contraction improves the nutrition of the heart muscle, the diuresis, which occurs if there be edema, lessens the burden upon the diseased heart. Although this drug is, in a large number of cardiac conditions, the most important remedy we possess it must not be regarded as a panacea for all forms of chronic heart disease. A discussion of the various forms of cardiac weakness in which this drug is indicated or contraindicated can scarcely be undertaken in this place, and the interested reader is referred to H. C. Wood, Jr.'s *Text-book of Pharmacology* for further information.

The active principles of digitalis are absorbable through the skin and the external application of digitalis poultices was formerly used to a considerable extent in the treatment of dropsies.

Two methods for the administration of digitalis have been advocated. The older and more frequently used is to begin with moderate doses —5 to 10 minims of the tincture three times a day—gradually increasing until some definite effect is obtained. The second method advocated by Eggleston (*J. A. M. A.*, 1920, lxxiv, 733) is to rapidly digitalize the patient. The principle of the Eggleston method is that it requires 0.15 cc. (approximately 2½ minims) of a standard tincture per pound body weight to produce maximum therapeutic results. From ¼ to ½ of this quantity may be given at once and followed by 1/10 of the dose every 6 hours, until the occurrence of either nausea, slowing of the pulse or cardiac irregularity; evidences of digitalis action. The method is not safe in patients who have previously received any drug of the digitalis group, and for its successful application requires a preparation that meets the physiological standard advocated by Doctor Eggleston, as well as continuous observation, and is therefore more suitable for hospital practice than ordinary clinical conditions.

Preparations of digitalis vary so much in their potency, and the conditions in which it is used so frequently demand the full actions of the drug, that the therapeutist should be guided in his dosage only by the degree of effect. The two most important symptoms indicating that the patient is taking as much as he can stand are great reduction in the rate of the pulse—say below sixty per minute—or the occurrence of nausea.

The symptoms of digitalis poisoning are nausea and vomiting, with muscular weakness, the pulse is at first very slow, may fall to thirty or forty a minute, and in severe cases later becomes very rapid and irregular. Visual disturbances, especially of the color sense, have been reported in several cases (see Sprague, *J. A. M. A.*, 1925, lxxxv). In some instances the pulse may be slow as long as the patient remains in a recumbent posture but becomes rapid if he assumes an upright position. Outside of the evacuation of the stomach and keeping the patient lying down there is no treatment of the poisoning which is known to be efficacious, although Zugsmith has reported favorable results from the external application of heat.

Preparations.—Because of the variability of the official preparation of digitalis and of their liability to produce gastric disturbances, a large number of proprietary preparations of the drug have been placed upon the market. It may be pointed out in connection with these substances that Hatcher and Weiss (*A. I. M.*, 1922, xxix, 690) have shown that the nauseating action of digitalis is due chiefly to a reflex from the heart to the vomiting center in the medulla, and that any preparation, therefore, which does not nauseate is therapeutically useless. In the second place, it is not probable that any single principle of the drug has exactly the same influence upon the circulation as the whole leaf. The following are some of the more important preparations of digitalis.

Digitalinum Gallicum, French digitaline, also known as *digitaline chloroformique* and as *Homolle's digitaline.* This is almost insoluble in water, and is said to consist largely of a glucoside allied to, or identical with, Kiliani's digitalin. The dose of the commercial article may be put down as about one two-hundred and sixtieth of a grain (0.00025 Gm.), to be repeated several times per day, the maximum daily dose being one-fortieth of a grain (0.0016 Gm.).

Digitoxin has been used to a certain extent clinically. According to the experiments of Fraenkel, however, it is more liable to give rise to cumulative effects than is the crude drug. It is almost insoluble in water and is locally irritant. *Dose,* one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

Digitalinum Germanicum, also known as *Merck's digitalin* or *German digitalin.* This is practically a concentrated extract of the digitalis seeds. It probably contains true digitalin, and digitalein, as well as digitonin. The dose is from one-tenth to one-half a grain (0.005–0.03 Gm.).

Digalen is claimed to be a *soluble digitoxin,* but such a statement is manifestly impossible. The claim of its discoverer Cloetta that it is isomeric with digitoxin but has twice the molecular weight of digitoxin, would seem to disprove its identity. According to Kiliani (*M. M. W.*, 1907), it is identical with digitalein.

Digipuratum is a yellowish powder which is asserted to contain all the active glucosides of digitalis leaves in the form of tannates without various objectionable constituents. It is physiologically standardized by tests upon frogs. The dose is the same as that of the leaves.

Digifolin is asserted to contain the cardiac principles without the saponins of digitalis. It is marketed in the form of tablets and of ampoulæ, each of which represents one and one-half of a grain (0.1 Gm.) of digitalis leaves. *Digipan* is a preparation of the same nature which is issued both in tablets and in solution, the dose of the tablets being one or two and of the solution fifteen drops (0.9 cc.). *Adigan* is also a saponin free preparation but does not seem to have been proven clinically. *Digitol* is standardized tincture made from leaves freed of their fatty matter by treating with benzin. The *dose* is the same as of the official tincture.

Of the various pure principles of digitalis the doses are as follows: *Digitalein,* one-sixtieth to one-thirtieth of a grain (0.0011–0.002 Gm.); *digitoxin,* one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.); *Kiliani's digitalinum verum* has not been used enough clinically to determine the proper dose. *Verodigen,* which is stated to be the same as gitalin, is given in doses of one-eightieth of a grain 0.0008 Gm.).

There are two substances known as *crystallized digitalin,* one of which, the *digitaline crystallisée* of the French Codex also known as *Nativelle's digitalin,* is probably identical with digitoxin. Merck's *crystallized digitalin* appears to be largely composed of digitonin and does not therefore represent the physiological properties of digitalis.

Dose, of digitalis leaves, one to two grains (0.065–0.13 Gm.).

DIOSCOREA. N. F.

DIOSCOREA Dioscor. [Wild Yam Root]

"Dioscorea consists of the dried rhizome of *Dioscorea villosa* Linné (Fam. *Dioscoreaceæ*). Dioscorea contains not more than 2 per cent. of foreign organic matter." *N. F.*

Wild Yam Root, Colic Root, Rheumatism Root.

The genus *Dioscorea* is represented by over 200 species which are native to tropical and temperate countries. They are all herbs with tuberous roots and twining herbaceous stems. Their leaves are broad, petiolate, frequently cordate, reticulately veined, and vary from simple, alternate or opposite to compound. Their flowers are small, greenish-yellow and diœcious and their fruits are 3-winged capsules enclosing winged seeds.

While *Dioscorea villosa* L. has long been considered the species yielding the drug, Bartlett finds this name no longer tenable on account of the confusion attending its use. He recognizes 5 species passing as *D. villosa,* namely *D. quaternata* Gmel., *D. Glauca* Muhl., *D. paniculata* Michx., *D. Lirticaulis* Bartlett and *D. floridana* Bartlett. For a detailed description of these see Bull. 189, *Bur. Pl. Ind., U. S. Dept. Agric.,* 1910. The species yielding the drug are all native to North America. The commercial supplies of the drug are obtained from Virginia, North Carolina, Indiana and Michigan.

Description and Physical Properties.—"*Unground Dioscorea.*—Knotted and woody, elongated, 6 to 20 mm. thick, often compressed, bent and branched, bearing scattered nodular projections, slender tough roots or thorn-like root-remains in circular depressions on the sides and underneath, and stem-scars on the upper surface; externally pale brown, surface more or less scaly from the partly detached, thin outer layer; fracture short but tough, the fractured surface whitish or pale-yellowish, with numerous small, scattered, yellowish wood-bundles. Odorless; taste starchy, insipid, afterwards acrid.

"*Structure.*—Rhizome: epidermis thin-walled, more or less detached; an outer layer composed of several rows of parenchyma cells with yellowish walls occasionally developing as a thin cork layer; a few rows of tangentially elongated thin-walled parenchyma, remaining tissue consisting chiefly of longitudinally elongated, thick-walled porous, partially lignified parenchyma containing starch, with numerous collateral fibrovascular bundles scattered throughout; raphides of calcium oxalate occasionally present in the parenchyma cells. Root; epidermal cells with yellowish thin walls; cortex composed of thin-walled, porous, slightly lignified parenchyma; endodermis distinct, the inner and radial walls being heavily thickened and slightly lignified; stele with a continuous zone of heavily lignified fibers, alternating small groups of tracheæ and sieve tissue and a pith composed of thick-walled, slightly lignified parenchyma. Sections of the root made close to the rhizome do not exhibit an endodermis.

"*Powdered Dioscorea.* — Whitish; exhibits numerous fragments of thick-walled, lignified parenchyma cells many of which contain spherical or ovoid starch grains up to 0.035 mm. in diameter; numerous isolated starch grains and a very few raphides of calcium oxalate; few fragments of thin-walled parenchyma cells; fragments of fibro-vascular bundles with tracheæ and tracheids which have minute border pores; yellowish or brownish fragments of epidermal tissue; few isolated lignified fibers." *N. F.*

W. C. Kalteyer found abundant saponin in the roots. (*A. J. P.,* 1888; see also *M. R.,* 1913, 311.) A substance, improperly called *dioscorein,* obtained by precipitating the tincture with water, is used in the *dose* of from one to four grains (0.0065–0.26 Gm.).

Dioscorea hirsuta Bl. grows in the island of Java, where it is known as *Gadoeng.* In 1894 W. G. Boorsma separated from it an alkaloid to which he gave the name of *dioscorine.* Plugge and Schutte (*A. J. P.,* 1897) assigned to it the formula $C_{13}H_{19}O_2N$, and found it to be a convulsant poison, resembling closely in its action picrotoxin, but much less active. Heckel and Schlagdenhauffen found a glucoside in the tuber of the *D. bulbifera* L. which grows in tropical Africa.

The *D. sativa* L., probably a native of Asia, is widely cultivated in the West Indies, its tuber being the popular amylaceous food called *yam.* The *D. alata* L. or *winged yam* yields a tuber which is popular in the southern states as a substitute for potatoes. The *D. Batatas* Decne. (*Chinese yam* or *cinnamon vine*) is also extentively used as a food in Asia.

From the *D. Tokoro,* a Japanese plant which is used as a fish poison, Honda (*A. E. P. P.,* 1904, li, p. 213) has separated several saponin substances. One of these, *dioscin,* is extraordinary for the strength of its hemolytic action, 1 part in 400,000 dissolving the coloring matter from the red cells in a 1 per cent. blood solution. It possesses also a strong toxic effect on fish and ameba. The root of *Dioscorea rhipogonoides* Oliver, under the names of *Cunao, Shu-Lang, faux gambier,* is exported in enormous quantities from Indo-China to Southern China for use as a dye-stuff.

Uses.—In large doses dioscorea exercises a nauseating effect and therefore may be expectorant and diuretic. By that group of practitioners who call themselves eclectics it was supposed to have antispasmodic powers and was regarded as a specific in *biliary colic,* whence its popular name of "colic root." It is very doubtful, however, whether this drug possesses any real therapeutic virtues.

Dose, one-half to one drachm (1.9–3.75 Gm.).

Off. Prep.—Fluidextractum Dioscoreæ, *N. F.;* Tinctura Viburni Opuli Composita, *N. F.*

DROSERA. N. F.

DROSERA Droser. [Sundew]

"Drosera is the air-dried flowering plant of *Drosera rotundifolia* Linné, frequently mixed with the closely allied species *Drosera anglica* Hudson and *Drosera longifolia* Linné, or at times wholly replaced by these (Fam. *Droseraceæ*). Drosera contains not more than 5 per cent. of foreign organic matter and yields not more than 10 per cent. of acid-insoluble ash." *N. F.*

Herba Rorellæ; Herba Roris Solio; Rosollis, Rosée du Soleil, *Fr.;* Sonnen-thau, *G.*

The Droseras or Sundews comprise about 90 species of small carnivorous plants common to peat bogs of both hemispheres but most abundant in Australia. They are characterized by possessing a much reduced fibrous root system from which springs a rosette of modified leaves, the upper surfaces of which possess numerous irritable, glandular hairs which secrete a viscid fluid that ensnares and catches insects. The hairs then bend over the insect and hold it in place while an acid fluid containing a protease is excreted by the glands that digest the animal tissues, the soluble nitrogenous products then being absorbed for the plant's nutrition. One or more scapes arise from the center of the leaf-rosette and terminate in scorpioid cymes of white, pink or crimson flowers. The N. F. recognizes 3 species of *Drosera,* all of which occur in bogs and moist sandy soil of Europe and North America. The leaf blades of *D. rotundifolia* L. are suborbicular, those of *D. Anglica* Huds. (*D. intermedia* Hayne) are spatulate, 2 to 3 times as long as wide, while those of *D. longifolia* L. are elongated spatulate-obovate 6 to 8 times as long as wide.

Description and Physical Properties.—"*Unground Drosera.*—Matted or broken leaves, stems and fibrous black rootlets; of a reddish color throughout; leaves mostly basal, petiolate. *Drosera rotundifolia;* blade orbicular, about 15 mm. in diameter, abruptly contracted into a slender pubescent petiole, upper surface covered with prominent pinkish red glandular tentacles, the latter up to 4 mm. in length; petiole slender, 2 to 4 cm. in length, 0.5 to 2 mm. in diameter, flattened and pubescent; scape filiform, smooth, from 10 to 30 cm. long, bearing a few five-parted, small, white fugacious flowers in a curved one-sided raceme. *Drosera anglica;* leaves linear—to obovate spatulate with blades 1.5–5 cm. long, 3–7 mm. wide, and glabrous or sparsely hairy petioles. *Drosera longifolia;* leaves spatulate with blades 2 to 3 times as long as they are wide, slender smooth petioles and scape, declinate at base. Odorless; taste faintly bitter and acidulous.

"*Powdered Drosera.*—Reddish brown; elements of diagnostic value; multicellular, oval heads of tentacles from 0.100 to 0.200 mm. in diameter; fragments of the multiseriate tentacle stalks; few glandular hairs with two-celled heads, the apical cells spreading and up to 0.095 mm. in width at the top; fragments of epidermal tissue with stomata, the latter up to 0.045 mm. in length; few fragments of fibro-vascular bundles with spiral tracheæ; fragments of parenchyma containing a reddish brown amorphous substance; a few rounded or ellipsoidal starch grains up to 0.012 mm. in diameter." *N. F.*

Chemists have failed to find in this plant any constituent more active than the vegetable acid which is probably citric or malic acid.

Uses.—Drosera was thought by the eclectic physicians to be useful in *whooping cough* and other pectoral complaints but probably is inert.

The *dose* of the crude drug is one drachm (4 Gm.).

Off. Prep.—Fluidextractum Droseræ, *N. F.*

DULCAMARA. N. F.

DULCAMARA Dulcam. [Bittersweet]

"Dulcamara is the dried stem of *Solanum Dulcamara* Linné (Fam. *Solanaceæ*). Dulcamara contains not more than 2 per cent of foreign organic matter." *N. F.*

Woody Nightshade; Stipites Dulcamaræ; Caulis Dulcamaræ; Tiges de Douceamère, (de Morelle grimpante), Douce amère, *Fr.;* Bittersüss, Bittersüss-Stengel, Hindischkraut, Alpranken, *G.;* Tallo de Dulcamara.

Dulcamara is a climbing shrub with a woody branching stem and purplish, cymose flowers, with lemon-yellow anthers. The bright scarlet berries remain after the falling of the leaves. The plant grows in wet places and around dwellings and is common to Europe and North

America, and in the United States grows from New England to Ohio. All portions of the plant are active. Fatal results from the eating of the berries by a child have been recorded. (*P. J.*, 1861.) For medicinal purposes the plant should be gathered in the autumn after the fall of the leaf, and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

Description and Physical Properties.—"*Unground Dulcamara.*—In short sections about 5 mm. or less in thickness, cylindraceous, outline of transverse section somewhat angular, longitudinally striate, more or less warty; bark thin, externally pale greenish, or light greenish brown, glabrous, marked with alternate leaf scars, internally green, the greenish or yellowish wood occurring in 1 to 2 concentric rings, usually hollow in the center. Odor slight; taste bitter, afterwards sweet.

"*Structure.*—Epidermis with a rather thick outer cuticle; several rows of cork composed of thin-walled cells and in the older stems entirely replacing the epidermis; phellogen composed of a number of rows of tangentially elongated cells; about six rows of collenchyma; a pericycle containing non-lignified fibers which are mostly in an interrupted single row; inner bark of parenchyma containing starch grains or sphenoidal micro-crystals of calcium oxalate, or groups of sieve cells; a continuous zone of cambium; a narrow zone of wood composed of numerous tracheæ, tracheids, wood fibers and lignified, porous parenchyma, the latter forming medullary rays one cell in width; within the wood a narrow zone of pith parenchyma with groups of sieve cells; pith surrounding a central hollow.

"*Powdered Dulcamara.* — Greenish yellow; exhibits tracheæ up to 0.112 mm. in diameter and with bordered pores or with spiral markings; tracheæ-like cells having pointed ends, slightly lignified walls and delicate spiral or reticulate markings; lignified wood fibers with few pores; non-lignified bast-fibers with walls up to 0.015 mm. thick; fragments composed of cork cells; very few, simple, unicellular hairs up to 0.800 mm. long, and with the lumina usually distinct in the lower portions only; starch grains, spheroidal, up to 0.012 mm. in diameter; sphenoidal micro-crystals numerous, up to 0.007 mm. long." *N. F.*

The dried twigs are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous odor. Their taste, which is at first bitter and afterwards sweetish, have given origin to the name of the plant.

According to Davis (*P. J.*, 1902, xv), dulcamara contains the glucosidal alkaloids *solanine* (see Part II) and *solaneine*, besides *solanidine*, which is a non-glucosidal alkaloid and is the hydrolytic product from solanine, and a bitter principle *dulcamarin.*

The *picroglycion* of Pfaff seems to be identical with dulcamarin. This was obtained by Blitz, in the following manner: The aqueous extract was treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with lead subacetate, the excess of this salt decomposed by hydrogen sulphide, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yielded the principle in small isolated crystals by spontaneous evaporation.

Uses.—In large doses dulcamara causes burning in the throat with nausea and vomiting and dizziness; the pulse temporarily accelerated becomes slow, the pupils dilated and there often occurs general weakness with convulsive muscular movements.

Formerly this drug was used in the treatment of *chronic rheumatism*, in *chronic bronchitis*, especially with an asthmatic tendency and in *whooping cough.* It was also attributed with anaphrodisiac properties. Today it is used almost solely in the treatment of scaly skin diseases such as *lepra, psoriasis*, and *pityriasis.*

Dose, thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Dulcamaræ, *N. F.*

ECHINACEA. N. F.

ECHINACEA Echin.

"Echinacea consists of the dried rhizome and roots of *Brauneria pallida* (Nuttall) Britton or *Brauneria angustifolia* (De Candolle) Heller (Fam. *Compositæ*). Echinacea contains not more than 3 per cent. of foreign organic matter. Echinacea must not be used after it has lost its characteristic odor and taste." *N. F.*

Nigger-head; Pale Purple Coneflower.

This composite perennial herb, a native of the prairie region of America west of Ohio, has been introduced by the so-called eclectic physicians as a remedy in divers dissimilar diseases. It possesses lanceolate, three- to five-nerved leaves and slender stems terminating in single, large, conical, purplish heads of ligulate and tubular flowers. Its fruits are 4-sided achenes, each with a short-tootheed pappus. The drug is collected in autumn, the commercial supplies coming from Kansas. Kraemer and Sollenberger (*A. J. P.*, 1911, p. 315) have described the physical characteristics of the drug.

Description and Physical Properties.—"*Unground Echinacea.*—Nearly entire, cylindrical, very slightly tapering and sometimes spirally twisted, from 10 to 20 cm. long and from 4 to 15 mm. in diameter; externally grayish brown, light brown or purplish brown; slightly annulate in the upper portion, with occasional stem scars somewhat longitudinally wrinkled, or furrowed; fracture short, fibrous; bark less than 1 mm. thick, wood composed of alternate light yellowish and black wedges; the rhizome with a circular or angular pith. Odor faint, aromatic; taste sweetish, followed by a tingling sensation suggesting aconite, but lacking the persistent and benumbing effect produced by that drug.

"*Structure.*—An outer cork composed of several layers of tabular cells with yellowish walls and containing oil globules or granular masses; about 8 rows of tangentially elongated rather thick-walled parenchyma cells among which are oil or resin canals; in the rhizome portion are a few strongly lignified bast fibers with thick walls and simple pores; a thick layer of parenchyma with numerous stone cells and oil or resin canals; characteristic carbon-like masses occur around the stone cells and fibers; sieve tissue in radial rows the latter separated by parenchyma containing inulin and extending to the middle bark; a distinct cambium zone of several rows of thin-walled cells; central portion made up of radially arranged groups of tracheæ, separated by broad wedges of parenchyma, the latter with secretion canals and characteristic stone cells.

"*Powdered Echinacea.*—Grayish; numerous stone cells, strongly lignified, from 0.018 to 0.042 mm. in diameter, many being very much elongated and carrying the characteristic carbon-like deposits; numerous tracheæ from 0.025 to 0.075 mm. in diameter and with simple pores, annular or reticulate markings, occasionally with bordered pores or double spiral markings; fragments of inulin-bearing parenchyma tissue, the latter showing oil or resin canals from 0.080 to 0.145 mm. in diameter and filled with a reddish brown or yellowish content; few fragments of cork and a few fibers." *N. F.*

Heyl and Hart (*J. Am. C. S.*, 1915, xxxvii, p. 1769) found the drug to contain inulin, 5.9 per cent.; inuloid, 6; sucrose, 7; vulose, 4; betaine, 0.1, and resins, 1.9 per cent.; the latter consisting of two isomeric phytosterols, phytosterolin, and the following fatty acids, oleic, linolic, cerotic and palmitic, but could find no physiologically active substance.

Brauneria purpurea, DC., Britton (*Rudbeckia purpurea* L., *Echinacea purpurea* Moench), *Black Sampson, Purple Cone-flower* (Virginia to Illinois and southward to Louisiana), is similarly used.

Uses.—Echinacea has been attributed with the property of increasing the resistance of the body to infection and is consequently used in *boils, septicemia,* and other infective conditions. Couch and Giltner (*J. Agricult. Research,* 1920, xx, 63) in a study on guinea-pigs failed to obtain any evidence of a beneficial effect in a variety of experimental infections. It is also attributed with aphrodisiac and analgesic powers, but is probably without therapeutic value. Hale (*Lancet Clinic,* March, 1901) injects an extract into the rectum in the treatment of *hemorrhoids.*

Dose, of the fluidextract, fifteen to thirty minims (1–2 cc.).

Off. Prep.—Fluidextractum Echinaceæ, *N. F.*

ELATERINUM. U. S.

ELATERIN Elaterin.

"A substance obtained from the juice of the fruit of *Ecballium Elaterium* (Linné) A. Richard (Fam. *Cucurbitaceæ*)." *U. S.*

Elaterine, Elatine, *Fr.;* Elaterin, *G.;* Elaterina, *Sp.*

Elaterin was introduced into the U. S. Pharmacopœia on account of the well-known variability in quality of commercial elaterium. (See *Elaterium,* Part II.) Care must be taken to examine the elaterin, which is itself liable to be adulterated. It may be procured by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassium hydroxide; this holds the green resin in solution, and the elaterin crystallizes as the liquor cools. Hennell obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which, being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. Flückiger prefers to exhaust elaterium with chloroform, and add to the percolate ether, which precipitates elaterin. The precipitate may be dissolved in chloroform and recrystallized. This process was adopted by the Br. Pharm., 1885. The yield of elaterin from elaterium is usually from 10 to 25 per cent.; the British Pharmacopœia 1898 required not less than 20 per cent.

According to Power and Moore (*Tr. Ch. Soc.*, xcvii, p. 99), elaterin consists of two isomeric substances, one lævorotary and physiologically inert, the active compound being dextrorotary. These they designate respectively as *alpha-* and *beta-elaterin.*

Description and Physical Properties.—"Minute white scales or prismatic crystals. It is odorless, and is stable in the air. Elaterin is insoluble in water. One Gm. is soluble in 325 cc. of alcohol, 310 cc. of benzene, 15.5 cc. of chloroform, and in 450 cc. of ether, at 25° C. One Gm. is soluble in 100 cc. of boiling alcohol.

"Its alcoholic solution is neutral to moistened litmus paper. To a solution of about 0.01 Gm. of Elaterin in 5 Gm. of melted phenol, add a few drops of sulphuric acid; the mixture becomes crimson, the color rapidly changing to scarlet. The ash from 0.1 Gm. is negligible. Shake 0.1 Gm. of Elaterin with a mixture of 9 cc. of distilled water and 1 cc. of diluted hydrochloric acid, and filter; separate portions of the filtrate yield no turbidity with 0.5 cc. of mercuric potassium iodide T.S. or iodine T.S. (*alkaloids*)." *U. S.*

Ernst Johannson (*In. Dis.*, Dorpat, 1884) gives the following reactions for elaterin besides those mentioned in the Pharmacopœia. In all of them elaterin is held in alcoholic solution. Froehde's reagent gives a green color passing into brown which fades away. Vanadin-sulphuric acid with the fortieth of a milligramme produced a splendid blue color passing into a clear green, finally into reddish-brown. After mixing with selenic acid and an addition of sulphuric acid, in a few minutes a red-brown color develops, which is not so deep as that which is produced by sulphuric acid. Kohler's reaction is produced by dissolving elaterin in a few drops of concentrated hydrochloric acid, evaporating the acid in a water bath, washing the white, amorphous residue with boiling water, and adding some concentrated sulphuric acid, when an amaranth-red color develops. By means of these reactions Johannson has been able to find elaterin in large quantities in the feces of animals poisoned by it, but no trace in the blood or urine or any part of the organism.

Uses.—Elaterin is a powerful hydragogue cathartic, frequently employed for the evacuation of *dropsy* especially in nephritic patients. Its too bold or frequent use is likely to prove debilitating and it should be employed only with great caution in persons of feeble constitution.

Dose, one-twentieth to one-tenth of a grain (0.003–0.006 Gm.).

Off. Prep.—Trituratio Elaterini, *U. S.*

ELIXIR AROMATICUM. U. S.

AROMATIC ELIXIR Elix. Arom. [Simple Elixir]

Elixir aromatique, *Fr.;* Aromatisches Elixir, *G.*

"Compound spirit of orange, 12 cc.; syrup, 375 cc.; purified talc, 30 Gm.; alcohol, distilled water, each, a sufficient quantity to make 1000 cc. To the compound spirit of orange add enough alcohol to make 250 cc. To this solution add the syrup in several portions, agitating after each addition, and afterwards add, in the same manner 375 cc. of distilled water. Mix the purified talc intimately with the liquid, and filter through a wetted filter, returning the first portions of the filtrate until a clear liquid is obtained. Lastly, wash the filter with a mixture of 1 volume of alcohol and 3 volumes of distilled water until the product measures 1000 cc.

"Alcohol content, by volume, 22 to 24 per cent." *U. S.*

This is justly one of the most popular vehicles of the Pharmacopœia. The flavor which is agreeable to nearly all palates is enhanced by its sweetness. If desired it can be colored with cochineal or caramel.

Off. Prep.—Elixir Aromaticum Rubrum, *N. F.*

ELIXIR GLYCYRRHIZÆ. U. S.

ELIXIR OF GLYCYRRHIZA Elix. Glycyrrh. [Elixir Adjuvans, Elixir of Licorice]

Adjuvant Elixir, Elixir adjuvant, *Fr.;* Gewürzhaftes Lakritzenelixir, *G.*

"Fluidextract of glycyrrhiza, 125 cc.; aromatic elixir, 875 cc.; to make 1000 cc. Mix and filter.

"Alcohol content, by volume, 21 to 23 per cent." *U. S.*

Uses.—This elixir is used as a vehicle for the administration of various medicinal preparations; it was introduced into the U. S. Pharmacopœia (8th Rev.) mainly to furnish an alternative elixir to aromatic elixir which is similarly used. The presence of the glycyrrhiza aids in disguising or obtunding the taste of bitter or disagreeable substance and the proportion might advantageously be increased.

ELIXIRIA

ELIXIRS

Cordials; Elixirs, *Fr.;* Elixire, *G.*

Elixirs as they are known in modern American pharmacy are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. They differ greatly from the liquids formerly termed elixirs, from the fact that the first object sought for in the modern elixir is an agreeable taste, and sometimes this is attained only by such sacrifices as to render the effect of the medicine almost *nil,* while the principal activity is due to the alcohol, which has proved in many cases very injurious. These considerations have prevented an extensive official recognition of elixirs, and the U. S. recognizes but two, which are used merely as vehicles. A number are, however, included in the N. F.

EMBELIA. Br.

EMBELIA

"*Embelia* is the dried fruit of Embelia Ribes, *Burm. fil.,* and also of Embelia robusta, *Roxb.*" *Br.*

The genus *Embelia* (Fam. *Myrsinaceæ*) includes a large number of creeping or almost climbing tropical shrubs. They possess petiolate leaves, small white flowers and are especially abundant in tropical Asia, *Embelia Ribes* extending as far as southern China. The fruits of this plant somewhat resemble black pepper and have been used as an adulterant of it.

Most of the drug is collected in India from *Embelia robusta.* The fruits of this plant are longitudinally striate whereas those of *E. Ribes* are wrinkled or warty.

It is officially described as "globular, about four millimetres in diameter, varying in color from dull red to nearly black; warty or striated longitudinally; superior, minutely beaked and often attached to a 5-partite calyx and slender pedicel. Pericarp brittle, enclosing a single seed surrounded by a delicate membrane. Seed reddish, marked with lighter spots. Endosperm horny and slightly ruminated. Taste slightly astringent and aromatic." *Br.*

If the powdered drug be shaken with ether and the resultant ethereal extract treated with diluted ammonia water a violet blue color is produced.

Embelia contains 2.5 per cent. of *embelic acid,* $C_9H_{14}O_2$, which occurs in golden yellow crystals, which are insoluble in water and soluble in alcohol, ether, chloroform and benzene; in alkaline solutions it dissolves with red coloration. There is present also small amounts of an alkaloid *christembine.*

Uses.—Embelia, under the names of *viranga, vayvirang* or *birang-i-kabuli,* has long been employed in India as an anthelmintic and has found its way into European commerce. It has but slight laxative properties, so that it is better to follow it by a purgative. It is especially tenicidal, the *tape worm* being expelled dead. The powdered drug may be given in milk early in the morning. Warden has found that *ammonium embelate* is an effective tenicide in dose of three grains (0.2 Gm.) for children and six grains (0.4 Gm.) or more for adults. As it is nearly tasteless and soluble it may be readily administered in syrup.

Dose, of embelia, one to four drachms (3.9–15.5 Gm.).

EMETINÆ HYDROCHLORIDUM. U. S.

EMETINE HYDROCHLORIDE Emet. Hydrochl.

"The hydrochloride [$C_{30}H_{44}O_4N_2.2HCl$] of an alkaloid obtained from ipecac or prepared synthetically. It contains variable amounts of water of crystallization." *U. S.*

This alkaloidal salt is made by dissolving emetine in diluted hydrochloric acid, concentrating the solution and separating the crystals. It should be free from cephaëline.

J. L. Ague (*Bol. Farm.,* Lima, through *C. D.,* 1920, 93) states that the emetine hydrochloride of commerce is not always pure but contains considerable amounts of cephaëline and psychotrine.

Description and Physical Properties.—"A white or very slightly yellowish, odorless, crystalline powder. Emetine Hydrochloride is freely soluble in water and in alcohol.

"An aqueous solution of the salt (1 in 100) yields precipitates with iodine T.S., with mercuric potassium iodide T.S., or with platinic chloride T.S. Sulphuric Acid, containing in each cc. about 0.005 Gm. of molybdic acid, when added to Emetine Hydrochloride produces a bright green color. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 2) a white precipitate insoluble in nitric acid.

"The ash from 0.2 Gm. is negligible. Emetine Hydrochloride dried to constant weight at 100° C. loses not more than 19 per cent (*water*). A solution of 0.1 Gm. of Emetine Hydrochloride in 10 cc. of distilled water requires for neutralization not more than 0.5 cc. of fiftieth-normal sodium hydroxide, using 1 drop of methyl red T.S. as indicator. One-tenth of 1 Gm. of the salt dissolves in 2 cc. of sulphuric acid without producing more than a faint yellow color (*readily carbonizable substances*). Dissolve 0.2 Gm. of Emetine Hydrochloride in 10 cc. of water, add 5 cc. of sodium hydroxide T.S., and shake, successively, with 20 cc. of ether, and then with 10 cc. portions of ether, until the residue obtained by evaporating 2 cc. of the last ether extraction, when dissolved in 1 drop of diluted hydrochloric acid and 1 cc. of water, no longer yields a distinct turbidity with iodine T.S. Discard the ether solutions, acidulate the aqueous liquid with diluted sulphuric acid, add ammonia T.S. until alkaline, and shake with four successive 10 cc. portions of ether. Evaporate the combined ether solutions to dryness on a water bath, and dry the residue at 100° C. Its weight does not exceed 0.004 Gm. (*cephaëline*).

"Preserve in dark amber-colored vials, protected from light." *U. S.*

A. Lahiele reports the following color reactions for emetine: calcium chloride, yellow; concentrated sulphuric acid and ammonium molybdate green, followed by blue; concentrated sulphuric acid and potassium dichromate, green, followed by blue; concentrated nitric acid, yellow.

For further discussion of the properties of emetine and other alkaloids of this drug see *Ipecacuanha.*

Uses.—The observations of Vedder indicating that the antidysenteric effect of Ipecac (see article on *Ipecacuanha*), was due chiefly to its emetine, led Rodgers to the hypodermic administration of emetine in the treatment of amebic *dysentery.* Since the publication of his paper (*B. M. J.,* 1912) this has become the standard treatment. In his original communication, Vedder asserted that a 1/1000 solution of emetine was sufficient to destroy the vitality of ameba. More recent experiments have thrown great doubt upon his optimism. Allen (*J. P. Ex. T.,* 1920, xii, p. 21) from his own experiments and study of the literature, reaches the conclusion that in some instances, one part of emetine in 15,000 would destroy the ameba in dysenteric stools but in other cases these parasites resisted a solution of 1/150 after two hours' exposure. Dale and Dobell (*J. P. Ex. T.,* 1917, x, 399), as the result of somewhat similar observations, believe "that the therapeutic efficacy of emetine is a result of its action upon the host rather than upon the parasite." Sellards and Leiva (*J. P. Ex. T.,* 1924, xxii, 467) conclude that although therapeutic doses do not directly kill the entamebæ, they so lessen their resistance that the natural bodily defences can destroy them.

The most important use of emetine in clinical medicine is in the treatment of *amebic dysentery.* For this purpose the hydrochloride may be given hypodermically or one of the insoluble salts (see *Emetine-Bismuth Iodid,* Part II) may be administered by mouth. While in nearly all cases of amebic dysentery the drug will cause a prompt amelioration of symptoms, in chronic cases even its continued use may fail to produce permanent cure. Whether the therapeutic results of emetine are superior to those of ipecac, in this disease, is at present open to difference of opinion although the ease of administration has made the alkaloid almost universally the choice. It appears to be of value also in amebic *abscess of the liver,* which is so common a sequela of chronic dysentery: Pontano (*Il Policlinico,* 1920, xxcii, p. 607) reports ten cases of apparent cure of hepatic abscess. Emetine has also been highly lauded by Tsykalas (*W. K. W.,* 1921, xxxiv, 579) and others in the tropical infection known variously as *bilharziasis* or *schistosomiasis.*

There is strong clinical evidence that emetine has a marked action on the coagulation of the blood. Blasco (Abst., *J. A. M. A.,* March, 1919) and others have reported most favorable results from its use in *hemoptysis* and Monroe (*Pract.,* 1918, ci, p. 167) has found it useful in *hemophilia.* The changes seen in the lungs after toxic doses of emetine would suggest that the drug has some other effect upon the pulmonary structures than that of a simple nauseant. Le Clair (*B. Hôp. Par.,* 1920, xliv, p. 802) has employed it with asserted great benefit in the treatment of *asthmatic emphysema.* Lewissohn (*J. A. M. A.,* 1918, lxxx, p. 9) has found that the injection of solutions of emetine into *cancer* will cause a complete microscopic disappearance of the growth but these effects seem to be purely those of a caustic and not due to any specific action of the drug upon the tumor.

Large doses of emetine, when injected subcutaneously or intravenously, cause death by a depressant action upon the heart muscle but this effect probably does not come into consideration in its therapeutic employment. Pellini and Wallace (*A. J. M. S.,* 1916, xvii, 420) have found that the administration of large doses of emetine causes a profound disturbance of metabolism—characterized by an increase in the output of nitrogen and the appearance of acidosis accompanied by a marked irritation of the alimentary canal. Kilgore and Liu (*A. In. M.,* 1917, xx, 178) have found uniformly that in dogs toxic doses of emetine lead to hemorhagic enteritis and also hemorrhages in the liver, spleen and kidney. A number of observers have noted that toxic effects will follow from the daily exhibition of comparatively small doses if continued for a long enough period of time. Dalimier (*Press. Med.,* 1917, xxv, 33) concludes that it is dangerous to give a total dose of more than 1 Gm. (16 grains) within a period of two weeks. According to Mappai (*B. Hôp. Par.,* 1920, xliv, 531), this accumulative toxicity of emetine is due to the fact that it is eliminated in an irregular or intermittent manner. The elimination of emetine—as has been shown by Guglielmetti (*Prensa Medica,* Argentina, 1917, iv, p. 20) is entirely through the alimentary canal and the liver.

A large number of cases of poisoning by emetine have been observed in human beings. The most constant symptom has been a bloody diarrhea. Levy and Rowntree (*A. I. M.,* 1916, xvii, 420) have reported acute kidney failure with acidosis; Johnson and Murphy (*P. J.,* 1917, xcviii, p. 139), two cases of pneumonic consolidation of the lung, apparently caused by emetine. Although we do not know of any fatality from a single dose several deaths from its repeated use have been reported; the smallest lethal amount with which we are familiar is 1.74 Gm. given in 19 days.

In the administration of emetine in dysentery it seems to be a matter of no great difference, either from the therapeutic or toxicological standpoint, whether the daily dose be administered in one, two, or three portions. To give it more frequently, however, exposes the patient to unnecessary discomfort, as the injections are quite painful.

The ordinary *dose* for the adult is from ½ to 1 grain daily (0.03 to 0.065 Gm.), but its use should not be continued for more than two weeks without interruption.

EMPLASTRA.

PLASTERS

Emplâtres, *Fr.;* Pflaster, *G.;* Empiastri, *It.;* Emplastos, *Sp.*

Plasters are solid preparations intended for external application, adhesive to the skin at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them Spread plasters are known as *sparadraps* (*Emplastra Extensa,* Fr. Cod.). Of recent years those having rubber in their composition are most largely used; they are usually perforated. Some plasters have as their basis a compound of olive oil and litharge. Others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change color and to become hard and brittle, and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be excluded as much as possible. The defect may usually be remedied by melting the plaster with a moderate heat and adding a sufficient quantity of oil to give it the proper consistence.

The spreading of plasters has become to a great extent a lost art to the pharmacists of this country, owing to the introduction of machine-spread plasters, which contain India-rubber in the adhesive composition. These are reasonably permanent, and do not require the application of heat. The perforation, or "porousing," of plasters is usually accomplished on a large scale by expensive apparatus.

Edmondson read a paper before the Pennsylvania Pharmaceutical Association in 1887 giving the process for manufacturing rubber-mass plasters on the large scale as follows: The principal ingredients employed are rubber, Burgundy pitch, gum olibanum, galbanum and orris root, with waxes or fats as excipients. The crude rubber is at first steeped in hot water, to cleanse and soften it, then the rubber is passed through the washer and crusher, where it is subjected to severe pressure between two corrugated rolls, eight inches in diameter and one foot wide, while a stream of water falling continually washes it thoroughly, and it comes out in sheets somewhat softened. After these sheets are dried, which requires a number of days, they are passed through the grinder, where they are crushed between two smooth rollers, fourteen inches in diameter and thirty-six inches across. This thoroughly softens the rubber and makes it plastic, so that it can be readily worked up with the other ingredients. The principal operation, the mixing, then takes place. The medication must be carefully combined, and the whole manipulation so managed that the plaster will be uniform, so that age or varying temperature shall not affect it. This operation is performed by means of rollers, sixteen inches in diameter, arranged so that one revolves at twice the speed of the other. Between these large rollers the mass is passed with whatever medication is required: *e. g.*, when a belladonna mass is to be made, a certain amount of the stock mass is taken and extract of belladonna in the proportions corresponding to the formula in the Pharmacopœia. These are repeatedly passed through the rollers until the extract of belladonna is thoroughly mixed with the mass, care being taken to keep the temperature from rising high enough to decompose or affect the alkaloids. The spreading is also done by rollers, into which the thoroughly mixed mass is fed at the same time that the cloth is fed, the thickness of the plasters being governed by the adjusting of screws on the side of the machine.

The rubber base is pliable, adhesive, it will not become too hard or too soft, but will yield up the medication to the absorbents of the skin, and its properties will be retained indefinitely. For formulas for plasters of former Pharmacopœias, see *U. S. D.*, 19th edition, p. 436 and for information concerning the extemporaneous spreading of plasters see *U. S. D.*, 20th edition, p. 413. The removal of plasters, either plain or medicated from the skin my be readily accomplished by moistening the back of the plaster slightly with ether, benzin or some other immiscible solvent, or by the use of a small amount of alcohol (medicated or denatured) which is allowed to flow under the plaster a few drops at a time beginning at one corner or edge of the plaster which may be slightly raised before applying the solvent.

Plasters which have lost their adhesiveness and have become brittle may be restored, according to K. Dieterich, by exposing them to the vapors of petroleum benzin for several days.

EMPLASTRUM ADHÆSIVUM. U. S.

ADHESIVE PLASTER Emp. Adhæs. [Emplastrum Elasticum, U. S. P. IX, Rubber Adhesive Plaster]

"A mixture of rubber, resins, and waxes, with a filler of an absorbent powder, such as zinc oxide, orris root, or starch, mechanically mixed and spread upon cotton cloth." *U. S.*

The term adhesive plaster was originally applied to the lead-base type of plaster (see *Emplastrum Resinæ*) which is still sold in several proprietary forms.

Sparadrapum Adhæsivum; Emplastrum Gummi Elastici; Emplatre Caoutchoute Simple, *Fr. Cod.;* Collemplastrum, *P. G.;* Esparadrapo Adhesivo de Caucho, *Sp.*

"The plaster mass should contain about 30 per cent. of pure rubber. When zinc oxide is used, it should represent at least 20 per cent. of the plaster mass. The mass must be free from nodules and spread evenly on a cotton fabric backing, having not less than 62 threads to each square cm., each piece of 100 square cm. weighing not less than 1.18 Gm. One hundred square cm. of the plaster should contain not less than 1.50 Gm. of the plaster mass. A strip of the plaster 5 cm. by 6.5 cm., applied to a hard wood surface for thirty minutes at a constant temperature of 37° C., should resist a tension of not less than 40 pounds when applied by a tensile strength machine or other suitable device, the pull being exerted parallel with the warp and with the longer dimension of the plaster." *U. S.*

Adhesive plaster should be applied at the body temperature. If properly preserved it will retain its adhesiveness for long periods. It should be protected from the effects of atmosphere by being wrapped in tin-foil or waxed paper; in the modern spools, or rolls, the outer layer affords a considerable degree of protection to the deeper ones.

Uses.—The uses of this popular substance are so numerous and various as to defy classification. Thus the surgeon utilizes it to immobilize various parts of the body, as in *sprains* and *strains;* to approximate the lips of *wounds;* to afford support in certain types of relaxations; to hold dressings in place; to make temporary repairs to various instruments and appliances, etc. In acute *pleurisy* or *pneumonia,* strapping the chest will often greatly assuage the pain, by preventing movement between the inflamed pleural surfaces. There is a general preference for those plasters which contain zinc oxide because of a common belief that they are less likely to irritate the skin, but even these, in sensitive individuals, may cause a very troublesome dermatitis.

Distinctive types of adhesive plaster—differing usually in the kind of cloth on which they are spread—intended for special uses by athletes, chiropodists, etc., are extensively employed.

EMPLASTRUM BELLADONNÆ. U. S., Br.

BELLADONNA PLASTER Emp. Bellad.

"Belladonna Plaster contains extract of belladonna corresponding to not less than 0.25 per cent. and not more than 0.30 per cent. of the alkaloids of belladonna leaves." *U. S.*

Emplâtre de Belladone, *Fr.;* Belladonna-Pflaster, *G.;* Emplasto de belladonna, *Sp.*

"Liquid Extract of Belladonna, 50.0 *millilitres;* Resin Plaster, 137.5 *grammes.* Concentrate the Liquid Extract of Belladonna by evaporation at a low temperature until it is reduced in weight to *twelve and a half grammes;* add the Resin Plaster, previously melted; mix. This Plaster contains 0.25 per cent. of the alkaloids of Belladonna Root, and is of one-half the strength of the Emplastrum Belladonnæ of the British Pharmacopœia, 1898," *Br.*

No process is given in the U. S. P. for making belladonna plaster. It is now made almost exclusively with a rubber base by manufacturers on a large scale.

Assay.—"Introduce 10 Gm. of Belladonna Plaster into a 100 cc. flask. (If the plaster is spread on fabric, cut the portion to be assayed into strips, weigh accurately, and introduce it into the flask.) Now add 50 cc. of chloroform, and shake the mixture until the plaster is dissolved. Pour the chloroform solution into a 250 cc. beaker, and wash the cloth upon which the plaster was spread with two successive portion of 25 cc. each of chloroform, adding the washings to the chloroform solution in the beaker. Then wash this cloth with 80 cc. of alcohol containing 1 cc. of ammonia T.S., and pour the washings into the chloroform solution in the beaker. Stir the mixture gently, and allow it to stand until the rubber has separated into a compact mass. Dry the cloth upon which the plaster was spread, weigh it, and subtract its weight from the first weight of the plaster. Pour the chloroform-alcohol solution into a 250 cc. separator, rinse the beaker and rubber with 10 cc. of alcohol, and add the rinsing to the separator. Completely extract the alkaloids from the chloroform-alcohol solution by shaking out repeatedly with weak sulphuric acid. Collect the acid washings in a separator, and add ammonia T.S. until the solution is decidedly alkaline to litmus paper, and completely extract the alkaloids by shaking out repeatedly with chloroform. Filter the chloroform solution through a pledget of purified cotton, evaporate it to dryness and dissolve the alkaloids from the residue in exactly 5 cc. of tenth-normal sulphuric acid, and titrate the excess of acid with fiftieth-normal potassium hydroxide. Each cc. of tenth-normal sulphuric acid corresponds to 0.02893 Gm. of the alkaloids of belladonna leaves (Proximate Assays)." *U. S.*

Uses.—Although belladonna plaster is a very widely used preparation it is essentially an irrational one. At times, sufficient of the active principle will be absorbed through the skin to produce constitutional symptoms. It is manifestly an uncertain and unsatisfactory mode of obtaining the general effects of belladonna and is never employed for this purpose. It is used purely as a local anodyne in *lumbago* and other *myalgias.* But atropine has comparatively feeble effects upon the sensory nerves. Moreover, in this type of inflammations the tissues involved are too deep-seated to expect to reach them directly by external applications. Such benefit as has followed the employment of belladonna plaster is due rather to the fixation to the parts of the plaster than to any action of the belladonna. A very popular type of belladonna plaster is one in which capsicum is also present. *Extract* of scopola was formerly largely used by manufacturers in making rubber-base belladonna plaster.

EMPLASTRUM CALEFACIENS. Br.

WARMING PLASTER

Emplastrum Picis Cantharidatum, *U. S.* 1890; Warm Plaster; Emplâtre de Poix cantharide, *Fr.;* Pechpflaster mit Canthariden, *G.*

"Cantharidin, 0.2 *gramme;* Chloroform, 20.0 *millilitres;* Olive Oil, 40.0 *millilitres;* Resin Plaster, 940.0 *grammes.* Dissolve the Cantharidin in the Chloroform, add the Olive Oil, and mix with the Resin Plaster, previously melted on a water bath. This Plaster contains 0.02 per cent. of Cantharidin, which is approximately the proportion contained in the Emplastrum Calefaciens of the British Pharmacopœia, 1898." *Br.*

Cantharidal pitch plaster or warming plaster is not official in the U. S. P. IX; the process of the U. S. P., 1890, will be found on p. 439, *U. S. D.,* 19th edition. The use of the blistering principle cantharidin dissolved in chloroform and olive oil will undoubtedly prove to be an improvement over the older process.

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication.

Warming plaster is employed in *chronic rheumatism,* and in chronic internal diseases attended with inflammation, such as *catarrh, asthma, pertussis, phthisis, hepatitis,* and the sequelæ of *pleurisy* and *pneumonia.*

EMPLASTRUM CANTHARIDIS. U. S.

CANTHARIDES PLASTER Emp. Canthar.

Fly Blister; Sparadrapum Cantharidis; Emplastrum Vesicans Extensum, Sparadrape Vesicant, *Fr. Cod.*

"Cantharides Cerate, Adhesive Plaster, spread on fabric, each, a sufficient quantity. Spread cantharides cerate upon the plaster, leaving a margin around the edges. It may also be spread on muslin, paper, or other suitable material. Each square cm. of spread plaster should contain 0.1 Gm. of cantharides cerate." *U. S.*

For formula of the British *Emplastrum Cantharidini* see under *Ceratum Cantharidis.*

Uses.—Cantharides plaster is used for the purpose of producing vesication in various deep-seated inflammations (see under *Cantharis*). It is at once the most certain and most convenient mode of obtaining the effects of Cantharides. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the applications should be continued for eight hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a flaxseed poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum. In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied, and from two to four hours are usually sufficient for any desirable purpose. When the head, or other hairy part, is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster, so that the abrasions may heal, and some impediment be offered to the absorption of the cantharidin. After the blister has been formed, it should be opened at the most depending parts, the cuticle being allowed to remain, and should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, rosin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, the application of an antiseptic desiccant powder, as iodoform or thymol iodide, is advantageous.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil, and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting *blistering cloth, blistering paper, vesicating taffeta,* etc. Since the recognition of an official spread plaster these preparations have been largely abandoned. For some of the formulas employed see *U. S. D.,* 20th ed., p. 314.

EMPLASTRUM CAPSICI. U. S.

CAPSICUM PLASTER Emp. Capsic.

"Capsicum Plaster contains not less than 0.25 Gm. of oleoresin of capsicum in each 15 square cm." *U. S.*

Sparadrapum Capsici; Sparadrap de Capsique, *Fr.;* Capsicumpflaster, *G.*

The present pharmacopœia gives no process for this plaster as it is usually made by machinery. The formula of the U. S. IX was as follows: "Oleoresin of Capsicum, Rubber Plaster—spread on fabric—of each, a sufficient quantity. Apply Oleoresin of Capsicum to the surface of the rubber plaster so as to leave a margin around the edges. Each fifteen square centimeters of spread plaster contains 0.25 Gm. of oleoresin of capsicum." *U. S. IX.*

The oleoresin should be laid on very evenly with a camel's-hair brush.

EMPLASTRUM HYDRARGYRI. Br.

MERCURIAL PLASTER

Emplastrum Mercuriale; Emplâtre mercuriel, *Fr. Cod.;* Emplastrum Hydrargyri, *P. G.;* Quecksilberpflaster, *G.;* Empiastro mercuriale, *It.;* Emplasto Mercurial Simple, *Sp.*

"Mercury, 328 *grammes;* Olive Oil, 18 *grammes;* Sublimed Sulphur, 2 *grammes;* Lead Plaster, 652 *grammes.* Heat the Olive Oil with the Sulphur until a reddish-brown liquid is obtained; with this solution triturate the Mercury until metallic globules are no longer visible; add the Lead Plaster, previously melted; mix." *Br.*

Mercurial plaster is no longer official in the U. S. P. The U. S. Pharm. VIII employed oleate of mercury and hydrous wool-fat for the purpose of extinguishing the mercury; this it does effectually, and at the same time increases the efficiency of the mercurial constituent. The quantity of mercury was 30 per cent. The British preparation is stronger, containing 32.8 per cent. For methods of assaying this plaster, see *A. J. P.,* 1911, p. 314; *C. D.,* 1911, p. 631; *P. J.,* 1911, p. 654.

Uses.—This plaster is employed to produce the local effects of mercury upon *syphilitic* lesions of the skin and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. It occasionally affects the gums.

It has been asserted by Serres and others that the mercurial plaster of the Codex (*Emplastrum* (*Emplâtre*) *de Vigo cum Mercurio,* see *U. S. D.,* 19th edition, p. 440) has the power, when applied over the eruption of *small pox,* before the end of the third day from its first appearance, to check its progress and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is probable that other mercurial preparations would answer the same purpose.

EMPLASTRUM MENTHOL. Br.

MENTHOL PLASTER

Emplâtre de Menthol, *Fr.;* Mentholpflaster, *G.*

"Menthol, 150 *grammes;* Yellow Beeswax, 100 *grammes;* Resin, 750 *grammes.* Melt the Beeswax and Resin together; when the mixture has cooled to about 70° C., add the Menthol, and stir until dissolved." *Br.*

This plaster is a mild counter-irritant, intended especially for relief in localized *neuralgia* and *rheumatic pains.*

EMPLASTRUM PLUMBI OLEATIS.

U. S. (Br.)

LEAD OLEATE PLASTER Emp. Plumb. Oleat. [Emplastrum Plumbi, U. S. P. IX, Lead Plaster, Diachylon Plaster]

Emplastrum Plumbi, *Br.;* Emplastrum Lithargyri, *Br.* 1864; Emplastrum Diachylon Simplex, Emplastrum Album Coctum; Litharge Plaster; Emplâtre simple, *Fr. Cod.;* Emplâtre de Plomb (de Litharge), Emplastrum simplex, *Fr.;* Emplastrum Lithargyri (simplex), *P. G.;* Emplastrum Cerusæ, Froschlaichpflaster; Bleipflaster, Diachylonpflaster, Gummipflaster, *G.;* Empiastro diachilon, *It.;* Emplasto de plomo simple, Emplasto simple, *Sp.*

"Lead Monoxide, 1000 Gm.; Olive Oil, 1000 Gm.; Lard, 1000 Gm.; Boiling Water, a sufficient quantity. Heat the olive oil and lard by a gentle heat until liquefied, in a bright copper or other suitable vessel of a capacity of not less than four times the bulk of the ingredients, sift the lead monoxide through a fine sieve, upon the surface of the hot liquid, and mix thoroughly. Then gradually add 350 cc. of boiling water, and boil the mixture, constantly stirring with a wooden spatula, and adding sufficient boiling water from time to time to replace that lost by evaporation, until the mass is homogeneous and a small portion removed and dipped into cold water is found to be pliable and tenacious. Then remove it from the fire, and wash several times with warm water to remove the glycerin. Finally knead the mass until it is free from water, roll it into cylinders of suitable size, and krap them in paper." *U. S.*

"Lead Oxide, 400 *grammes;* Olive Oil, 800 *grammes;* Distilled Water, 400 *millilitres,* or a *sufficient quantity.* Boil gently together in a steam-bath, stirring constantly until combination has been effected. When cool remove the plaster-like mass produced; knead it thoroughly with hot water, and allow it to dry." *Br.*

In the U. S. VIII an innovation in the preparation of this plaster was introduced. It was directed to be made by the precipitation produced between solutions of soap (sodium oleate) and lead acetate instead of by the time-honored method of boiling litharge, olive oil, and water together. The resulting product was chemically nearly identical with that made by the boiling process and much whiter in color, but experience proved that the precipitation method produced a plaster which does not keep as well as did the plaster made in the old way, hence the U. S. has returned to the former process, although the olive oil is partially replaced by lard.

The reaction in the U. S. P. VIII process, disregarding the palmitin present, was as follows:

$$\underset{\text{Sodium oleate}}{2NaC_{18}H_{33}O_2} + \underset{\text{Lead acetate}}{Pb(C_2H_3O_2)_2} = \underset{\text{Lead oleate}}{Pb(C_{18}H_{33}O_2)_2} + \underset{\text{Sodium acetate}}{2NaC_2H_3O_2}$$

In the U. S. X and the British process a reaction takes place expressed approximately by the following reaction:

$$\underset{\text{Olein}}{2C_3H_5(C_{18}H_{33}O_2)_3} + \underset{\text{Litharge}}{3PbO} + \underset{\text{Water}}{3H_2O} = \underset{\text{Lead oleate}}{3Pb(C_{18}H_{33}O_2)_2} + \underset{\text{Glycerin}}{2C_3H_5(OH)_3}$$

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to Henry, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. The British process does not provide for the separation of the glycerin and the plaster is not kneaded to separate the water, both of which, in our opinion, are necessary to produce the best result and which form part of the U. S. P. process.

The following description gives an outline of the method used in the large-scale manufacture: The vessel in which the lead plaster is prepared should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would, therefore, delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process, and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator.

During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbon dioxide, which is liberated by the fatty acids from traces of lead carbonate sometimes contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the color and consistence of the mass. The color of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red spots, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such, at least, has been the course of proceeding usually recommended. But Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. Bernbeck found that lead plaster could be preserved from hardening and oxidation if kept in air tight canisters. (*Ph. Ztg.*, 1881, p. 589.)

Zinc Plaster.—De Mussey, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of zinc oxide, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide, and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of zinc sulphate being mixed, a copious precipitate takes place of zinc oleopalmitate, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence.

Uses.—This plaster, which has long been known under the name of *diachylon,* is used as an application to excoriated surfaces and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long continued application to a large ulcer of the leg. (*Am. J. M. S.*, xxiii, 246.) Its chief use is in the preparation of other plasters. See *Logan's Plaster, Mahy's Plaster, U. S. D.*, 19th edition, p. 443.

Off. Prep.—Emplastrum Resinæ, *U. S., Br.;* Emplastrum Hydrargyri, *Br.;* Emplastrum Saponis, *N. F., Br.;* Unguentum Diachylon, *U. S.*

EMPLASTRUM RESINÆ. Br.

ROSIN PLASTER Emp. Res. [Rosin Adhesive Plaster, Adhesive Plaster]

Resin Plaster, *Br.;* Resin Adhesive Plaster; Emplâtre Adhésif, Emplâtre Résineux, *Fr.;* Emplastrum adhæsivum, *P. G.;* Heftpflaster, *G.;* Emplastro adesivo, *It.*

"Resin, 100 *grammes;* Lead Plaster, 850 *grammes;* Hard Soap, 50 *grammes.* Melt each ingredient separately at as low a temperature as possible; mix." *Br.*

Resin plaster was dropped at the Tenth Revision of the U. S. Pharmacopœia. It differs from lead plaster in being more adhesive and somewhat more stimulating. The soap is added to give it greater pliability, and render it less liable to crack in cold weather, without impairing its adhesiveness. It is usually spread upon muslin, and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept ready spread by the pharmacist; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed.

As an adhesive plaster this has been almost completely displaced by plasters made with a rubber base. (See *Emplastrum adhæsivum.*) It is used only as a base for applying more active drugs to the skin.

EMPLASTRUM SAPONIS. Br.

SOAP PLASTER

Emplâtre de Savon, *Fr. Cod.;* Emplastrum cum Sapone, *Fr.;* Emplastrum Saponatum, *P. G.;* Seifenpflaster, *G.;* Emplasto de jabon, *Sp.*

"Hard Soap, 140 *grammes;* Lead Plaster, 835 *grammes;* Resin, 25 *grammes.* Melt each ingredient separately at a low temperature; mix; evaporate, with constant stirring, to a proper consistence." *Br.*

Soap plaster is not recognized by the U. S.; a preparation similar to, but not identical with, the British is in the National Formulary.

Soap plaster is considered discutient, and is sometimes used as an application to tumors, where a dressing is required. Somewhat softer in its character, the *soap cerate,* formerly official, may be found useful. This was made as follows: *Ceratum Saponis.* "Take of Soap Plaster *two troyounces;* White Wax *two troyounces and a half;* Olive Oil *four troyounces.* Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.*, 1870.

EMPLASTRUM SINAPIS. U. S.

MUSTARD PLASTER Emp. Sinap. [Mustard Paper]

"A uniform mixture of powdered black mustard (deprived of its fixed oils), and a solution of rubber, spread on paper, cotton cloth or other fabric. Each 100 square centimeters contains not less than 2.5 Gm. of black mustard deprived of its fixed oil." *U. S.*

Charta Sinapis, *U. S. VIII;* Mustard Paper; Mustard Leaves; Sinapisme en feuille, *Fr. Cod.;* Papier Moutarde, Papier Sinapisé, *Fr.;* Charta sinapisata, *P. G.;* Senf-papier, *G.;* Carta senapata, *It.;* Papel sinapico, Charta sinapica, *Sp.*

The present Pharmacopœia gives no process for this plaster. That formerly official was as follows:

"Black Mustard, in No. 60 powder, *one hundred grammes;* Rubber, *ten grammes;* Petroleum Benzin, Carbon Disulphide, each, a *sufficient quantity.* Pack the Black Mustard in a conical percolator, and gradually pour Petroleum Benzin upon it until the percolate ceases to produce a permanent, greasy stain upon blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the Rubber in a mixture of *one hundred cubic centimeters,* each, of Petroleum Benzin and Carbon Disulphide, mix the purified Mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather thick, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 Gm. of Black Mustard deprived of oil. Before it is applied to the skin, Mustard Paper should be dipped in warm water for about fifteen seconds." *U. S. VIII.*

"When moistened thoroughly with tepid water and applied to the skin, the Plaster produces a decided warmth and reddening of the skin within five minutes. Preserve in tightly-closed containers.

"Before Mustard Plaster is applied, moisten it thoroughly with tepid water." *U. S.*

Solution of gutta-percha is unsuited for use in this preparation, on account of want of adhesiveness, and the tendency of the mixture, when dry, to crack and peel off. We have used instead a solution of 1 part of pure rubber in 30 of equal parts of carbon disulphide and petroleum benzin. On the large scale, by means of a plaster spreading apparatus a uniform coat of this solution may be applied to paper. As the latter passes out from under the apparatus, a sieve containing the powdered mustard is shaken over it; this is fixed by the adhesive coat and firmly retained after the evaporation of the volatile liquids in a warm place. The application of the powdered mustard must be properly regulated according to the speed with which the machine delivers the coated paper. The paper is cut into pieces of convenient size, and needs only to be wetted with tepid water to be ready for use. Owing to the fact that the large manufacturers can put mustard paper upon the market at such low rates that it pays the apothecary better to buy than to prepare it, and it is rarely made in the retail stores.

Mustard plaster is especially subject to deteriorating influences. It should never be exposed to a damp atmosphere for any length of time before using. Commercial mustard plasters are available spread either upon cloth or upon paper. They should be kept in well-closed containers.

Uses.—For the uses of the mustard plaster, see *Sinapis.*

Experience has shown that the ready-made mustard papers err rather from too much than from too little activity. Moreover, their action cannot be regulated with the same nicety as can that of the mustard poultice. Unless in the case of travellers, and of others who must wait upon themselves, the domestic application is preferable. The *mustard leaves* can rarely be borne for more than fifteen minutes.

EMULSA.

EMULSIONS

Emulsions, *Fr.;* Emulsiones, *G.;* Emulsiones, *It., Sp.*

Under this head are included in the U. S. Pharmacopœia liquid preparations in which oleaginous substances are suspended in aqueous fluids by the intervention of gum or other viscid matter. The preparations forming the present class of emulsions were termed Mixtures in earlier pharmacopœias, and it is to be regretted that under this indefinite term are still grouped liquids of many kinds; the separation of these into proper classes is only a question of time, and the introduction of this new class into the Pharmacopœia of 1890 marked the first step in the direction of greater accuracy in defining pharmaceutical preparations, and more system in classification. The object of emulsions is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect emulsions. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the aqueous vehicle is added. In the case of the liquid balsams and oils, if gum arabic is employed as the intermedium it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia. When a fixed oil, oleoresin, or balsam is to be made into an emulsion, the method most employed abroad is to add one part of gum to two or three of the oil, in a mortar, triturate until the mixture is complete, and then add at once twice as much water as gum used, and triturate rapidly until the oil is completely emulsified, then gradually add the remainder of the vehicle with constant trituration. Agitation in a bottle is sometimes substituted for trituration. Another plan which is frequently used, especially in the preparation of emulsions extemporaneously is to make the emulsion with mucilage. Having a broad flat pestle and a mortar perfectly free from grease, put in a little mucilage, rub it around the mortar, add about half as much oil, triturate from the center so as to emulsify this, then add more mucilage, then oil, and so on until the operation is completed. Care is required never to get the oil in excess of the mucilage. This plan seems to accord with the principle laid down by R. Rother, that the most perfect and rapid emulsifier is a perfect emulsion.

The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. The white of egg has been sometimes used as the suspending substance, but it is inferior for this purpose to the yolk, or to gum arabic. When volatile oils are to be emulsified it is an advantage to mix them with an equal volume of inert fixed oil to promote stability. Soap is valuable as an emulsifying agent for some purposes. Quillaja, saponin, and other substances having similar properties have been proposed as emulsifying agents, but they are objectionable on account of their medicinal activity. Emulsifying agents should be inert.

Leo Roon (*J. A. Ph. A.*, 1916, v, 496) gives an extensive review of the literature on emulsification and Roon and Oesper have made an important contribution to the theory of emulsification (*J. I. E. C.*, 1917, p. 156). The authors agree with Fischer (*Science*, 1916, p. 468) that emulsification is due to, or accompanied by, the formation of a hydrated colloid compound. Both the English and Continental methods of emulsification were studied carefully. The unsatisfactory results obtained by the majority of workers with the English method, are alleged to be due to the fact that the hydration of the emulsifying agent occurs progressively and not all at one time and for the greater part is not accomplished in the presence of the internal phase (oil). In the Continental method all of the emulsifying agent (colloid) is hydrated at one time and in the presence of the internal phase (oil). After experimenting with various proportions of materials, it is stated by the authors that the best and quickest results are obtained by the use of the following proportions in the preparation of the original nucleus: oil 4, water 3, gum 2.

Experimental emulsions were produced of the following substances: hexane, sp. gr. 0.691; chloroform, sp. gr. 1.526; carbon tetrachloride, sp. gr. 1.597; benzene, sp. gr. 0.877; oil of turpentine, sp. gr. 0.85; mineral oil, sp. gr. 0.853; cottonseed oil, sp. gr. 0.921. Gum emulsions and soap emulsions were made of all these and the conclusions, in part, were as follows: 1. The presence of a hydrated colloid is necessary for emulsification. 2. This hydration compound is most efficiently used if formed at the moment of dispersion of the internal phase—in other words, the three constituents, internal phase, emulsifier and water, in critical proportions, must all be mixed at one time in order to form a properly hydrated nucleus. 3. Slight variations from the proper procedure or from the critical proportions yield either less stable emulsions or none at all. 4. No emulsion results if the emulsifier is diluted before the dispersion of the internal phase.

When two liquids are emulsified together the question often arises which is the internal phase, which the dispersion medium. It is usually the case that when one liquid is in considerable excess, it becomes the dispersion medium, but this does not always follow. In the nomenclature of emulsions the first term in the compound title always indicates the dispersed (internal) phase. Thus a water-oil emulsion is one in which oil is suspended in water, an oil-water emulsion is one in which the reverse condition obtains. Carron oil is an example of the oil-water type of emulsion and cod liver oil emulsion of the water-oil type.

An excellent review of the theories of emulsification is given by W. Clayton in *J. Soc. Chem. Ind.*, 1919.

EMULSUM ASAFŒTIDÆ. U. S.

EMULSION OF ASAFETIDA Emuls. Asafœt. [Milk of Asafœtida]

Asafetida Mixture; Mistura (Lac) Asafœtidæ, Mistura Asafœtida, *U. S. P.* 1880; Mixture (Lait) d'Asafœtida, *Fr.;* Asafœtidaemulsion, Stinkasantmilch, *G.*

"Asafetida, in tears or selected masses, 40 Gm.; Water, a sufficient quantity of make 1000 cc. Rub the asafetida in a mortar with 900 cc. of water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and rinse the mortar and strainer with enough water to make the product measure 1000 cc. Mix thoroughly." *U. S.*

This emulsion is less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable odor and taste are, however, objections, which induce a frequent preference for the last mentioned preparation. It is very often employed as an enema. From two to four fluidounces (60–120 cc.) may be given by the rectum. D. Ackerman prepares a concentrated *emulsion of asafetida,* which will keep if excluded from the light, by using a mixture of three-fourths of pure water and one-fourth of diluted acetic acid as the menstruum. For cleaning mortars in which asafetida has been rubbed, he recommends solution of potassium hydroxide, followed by soap and water. The use of an oily meal, like linseed meal or almond meal, has been recommended for the same purpose.

Dose, one-half to one fluidounce (15–30 cc.).

EMULSUM OLEI MORRHUÆ. U. S.

EMULSION OF COD LIVER OIL Emuls. Ol. Morrh.

Emulsion de Huile de Foie de Morue, *Fr. Cod.;* Leberthranemulsion, *G.* Emulsio Olei Jecoris Aselli, *P. G.;* Emulsion de Accite ce Higado de Bacalao, *Sp.*

"Cod Liver Oil, 500 cc.; Acacia, in very fine powder, 125 Gm.; Syrup, 100 cc.; Methyl Salicylate, 4 cc; Water, a sufficient quantity, to make 1000 cc. Thoroughly mix the acacia with the cod liver oil in a dry mortar or other suitable vessel, then add at once 250 cc. of water, and complete the emulsification by trituration or by the aid of a suitable mechanical device. When a thick, white, homogeneous mixture is obtained, add the methyl salicylate and the syrup with sufficient water to make the product measure 1000 cc., and mix thoroughly. [NOTE.—The methyl salicylate may be replaced by a suitable quantity of any other flavoring.] This emulsion is intended to be freshly prepared as required. If it is to be kept for any length of time, 70 cc. of alcohol should be added, replacing a corresponding volume of water. The alcohol should be added last and in small portions, shaking after each addition." *U. S.*

This emulsion was introduced into the U. S. P. for the purpose of affording a simple process for making a reasonably palatable and permanent preparation of cod liver oil. The Continental method is best adapted for stock emulsions; to those who object to the taste of a combination of syrup and an oil with a fishy taste, the emulsion may be flavored with bruised celery seed and salt and then strained. A very palatable preparation of this type has been prepared in which the flavoring agents used were Worcestershire sauce and mustard. (See *Emulsum Olei Morrhuæ cum Hypophosphitibus,* N. F.) A comparison of various flavors for this emulsion was made by G. M. Beringer, Jr. (*Proc. N. J. Ph. A.,* 1914, p. 81), in which it is asserted that the best disguising flavors are those of coriander and geranium; next came anise and cardamom, then bitter almond, clove, pimenta and vanilla. Of inferior value in this respect were peppermint, spearmint, lemon, orange and cinnamon and least valuable of all were caraway, sassafras, wintergreen and nutmeg. An excellent emulsion is made with malt extract as the emulsifying agent (see *Emulsum Olei Morrhuæ cum Malto,* N. F., Part III). The N. F. includes a number of other emulsions of cod liver oil.

Under the name of *Black Bottle,* there has long been used in New England an emulsion of cod liver oil flavored with licorice and aromatic oils, the following formula for which was contributed to the *Apothecary,* 1913, p. 24, by R. A. Newton: Powdered Acacia, 13 dr.; cod liver oil, 6½ fl. oz.; flavoring oils, 15 min.; pure extract of licorice, 5 dr.; glycerin, 2½ fl. oz.; water, to make 1 pint. Prepare an emulsion.

The flavoring oil mixture is made as follows: Oil of cassia, 1 fl. oz.; oil of lavender, ½ fl. oz.; oil of clove, 1 fl. dr.; oil of peppermint, ½ fl. dr.; mix.

Dose, two to four fluidrachms (7.5–15 cc.).

EMULSUM OLEI TEREBINTHINÆ. U. S.

EMULSION OF OIL OF TURPENTINE
Emuls. Ol. Tereb.

Emulsion d'Essence de Térébenthine, *Fr.;* Terpentinölemulsion, *G.*

"Rectified Oil of Turpentine, 15 cc.; Acacia, in very fine powder, 5 Gm.; Water, a sufficient quantity, to make 100 cc. Place the powdered acacia in a dry bottle, add the oil of turpentine, mix thoroughly, add exactly 10 cc. of water, and agitate briskly until an emulsion forms. Then add sufficient water to make the product measure 100 cc. and mix thoroughly." *U. S.*

The present formula differs from that of the previous Pharmacopœia in the omission of the expressed oil of almond. This we believe to be unfortunate as the presence of the fixed oil not only tends to stabilize the emulsion but also renders the turpentine less irritant to the stomach. It might advantageously be reduced in strength much like the one recommended by J. Winchell Forbes, and a mortar and pestle are not needed to produce a perfect emulsion.

Dose, twenty to sixty minims (1.2–3.7 cc.).

EPINEPHRINA. U. S. (Br.)

EPINEPHRINE Epineph. [Lævo-Methylaminoethanolcatechol]

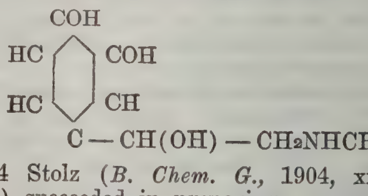
"$C_9H_{13}O_3N$." *U. S.*

"Adrenalin, or lævo-methylamino-ethanolcatechol, $C_9H_{13}NO_3$, may be obtained from the suprarenal glands of animals." *Br.*

Adrenalinum, *Br.;* Adrenalin, Suprarenalin, Suprarenin.

In 1897 Dr. John Abel (*J. H. H. B.,* July, 1897) separated from the suprarenal capsule the benzoyl-chloride of a base to which he gave the name epinephrine. The pure base was isolated in 1901 almost simultaneously by von Furth, who named it *suprarenin,* and Takamine, who named it *adrenalin,* the latter of whom patented the name and product. For description of suprarenal glands, which were formerly official see under *Organotherapy,* Part II.

As the result of much investigation into the nature of this substance it has been determined to be ortho-dioxyphenyl-ethanol-methyl-amine with the following structural formula:



In 1904 Stolz (*B. Chem. G.,* 1904, xxxvii, p. 4149) succeeded in preparing a compound synthetically which differed from the natural alkaloid only in being optically inert and much weaker physiologically. Flacher (*Z. P. C.,* 1908, lviii, p. 189) showed that the synthetic alkaloid was really the optically inactive racemic form and consisted of two principles, one dextro- and the other lævo-rotatory, and Abderhalden and Mueller (*Z. P. C.*, lviii, p. 185, and lxii, p. 484) and Cushny (*J. P.*, 1908, xxxvii and xxxviii) have shown that the lævo-rotatory form was nearly fifteen times as active as the dextro-rotatory.

The following method for separating this principle is given by Takamine (*A. J. P.*, 1901, p. 523): The comminuted suprarenal capsules are steeped in acidulated water for five hours at a temperature of from 50° to 80° C. with frequent agitation. At the end of this time the temperature is raised to 95° C. for a period of an hour to coagulate albuminous matters. As the adrenalin is prone to absorb oxygen from the air it is necessary to avoid exposure of the liquid as much as possible; a layer of fat floating on the surface acts well for this purpose and at the same time has the effect of retarding evaporation of the water. The liquid portion is separated by straining and the precipitate expressed and afterwards steeped for several hours in a fresh quantity of acidulated water in order to extract any residual alkaloid. The two liquid portions are united and allowed to separate from the oil and then partially evaporated in a vacuum pan. To this concentrated solution about two or three times its own volume of strong ethyl or methyl alcohol is added which precipitates various inert substances which may be removed by filtration. The alcoholic solution is then partially evaporated and ammonia added until distinct alkalinity. After standing several hours a yellow brownish precipitate is formed which is an impure basic form of adrenalin. This precipitate is washed with water and dried and further purified by dissolving in dilute acid and adding alcohol and ether which precipitate the coloring matter and inorganic impurities. To the filtrate from this precipitation ammonia is added which precipitates the adrenalin as almost colorless crystals. They may be further purified by repetition of the same process.

There are a number of processes for preparing this principle synthetically. The following is an outline of the most important of these methods: Pyrocatechol, $C_6H_4(OH)_2$ 1 : 2, is acted upon with chloracetyl chloride $CHCl_2COCl$ which unites to form a condensation product known as chloracetocatechol, $C_6H_3(OH)_2COCH_2Cl$. This product is then acted upon with methylamine, CH_3NH_2 which produces a compound known as *adrenalone* (amino-methyl-aceto-catechol) $C_6H_3(OH)_2COCH_2NHCH_3$. This is then reduced by nascent hydrogen to yield r-adrenalin, $C_6H_3(OH)_2CHOHCH_2NHCH_3$. This racemic, or optically inactive, adrenalin is then acted upon with an alcoholic solution of dextro-tartaric acid which dissolves the dextro and leaves behind the lævo modification.

Description and Physical Properties.—"A white or light brownish, microcrystalline, odorless powder, gradually darkening on exposure to the air. Epinephrine is very slightly soluble in water and in alcohol. It is insoluble in ether, chloroform, acetone, and in fixed or volatile oils.

"Epinephrine combines with acids, forming salts which are readily soluble in water, and from these solutions the base may be precipitated by ammonia or alkali carbonates. The acid solution is not affected by solutions of trinitrophenol, tannic acid, phosphomolybdic acid, mercuric potassium iodide, or platinic chloride. A saturated aqueous solution of Epinephrine is slightly alkaline to litmus paper. A slightly acid, aqueous solution of Epinephrine (1 in 1000) gives with ferric chloride T.S. an emerald-green color, turning to cherry-red and finally to brown on standing. Other oxidizing agents produce red, pink or violet colors which change to brown. Fixed alkali hydroxides cause the solution to darken on standing, but do not precipitate the Epinephrine. The ash from 0.1 Gm. is negligible.

"Preserve in well-closed containers, protected from light." *U. S.*

It is described by the British Pharmacopœia as "a light-brown, or nearly white, microcrystalline powder. Very slightly soluble in *water;* almost insoluble in *alcohol* (90 per cent.), in *ether,* and in *chloroform.* Combines with acids to form salts which are readily soluble in *water* and in *alcohol* (90 per cent.). Melts, with partial decomposition, between 205° and 212° C. Alkaline to moistened *litmus paper.* A diluted, slightly acid solution gives with a trace of *ferric chloride* an emerald-green color which is changed to purple or carmine by the cautious addition of a dilute solution of *sodium hydroxide;* readily reduces *solution of auric chloride;* gradually develops a characteristic unpleasant odor when a small quantity is mixed with five times its volume of *solution of sodium hydroxide;* yields no precipitate with *solution of potassio-mercuric iodide* (absence of most alkaloids). No appreciable ash." *Br.*

It has a slightly bitter taste and leaves a numb feeling on the tongue where it has been applied. Although its solutions readily undergo oxidation, in the dry form it is stable. It is easily soluble by dilute acids and by alkali hydroxides, forming salts, although not dissolved by ammonia or the carbonates. The alkaline solution absorbs oxygen very readily, in proportion to its alkalinity.

The following are some of the characteristic reactions: Ferric chloride colors epinephrine solution emerald green. A careful addition of caustic alkali to the green solution produced by ferric chloride, gives rise to the various shades of hue ranging from purple to carmine red, which are destroyed by careful neutralization with acids, restoring its original green color. Iodine as well as oxidizing agents, such as nitric acid, potassium bichromate and ferricyanide, etc., give a vivid pink.

A sensitive color test for epinephrine has been proposed by Moreschi (*Gaz. Med. Ital.*, 1913, 41), as follows: A small amount of tincture of iodine is cautiously floated upon the suspected liquid. In the presence of epinephrine a pink ring will be formed at the zone of contact, which gradually spreads into the lower liquid and then rapidly disappears. On then adding a few cc. of 1/1000 aqueous solution of sodium persulphate, a reddish or violet color will appear. This test will detect 1 part of epinephrine in two million of solution.

Gold chloride is very energetically reduced by epinephrine and a complete separation of the metal follows, from acid solution, by application of gentle heat; resultant liquid is colored pink or carmine red according to the strength of the solution used, as is the case with different oxidizing agents.

These color reactions, while satisfactory for identification tests, have not been found to be applicable for quantitative determinations. (See *Liquor Epinephrinæ Hydrochloride.*)

None of the following alkaloidal reagents produce precipitation: Mercuro-potassium iodide, picric acid, tannic acid, phosphomolybdic acid, phospho-tungstic acid, mercuric chloride, lead acetate, potassium bichromate, and platinum chloride.

Epinephrine is a substance of extreme chemical sensitiveness especially easily affected by oxidizing agents, but also being destroyed by alkalies, free halogens, and the salts of easily reducible metals such as iron. Beckwith (*J. A. Ph. A.*, 1914, iii, p. 1547) has shown that if protected from light, heat, and air, solutions of epinephrine will retain their activity for long periods of time. He found that the presence of slight excesses of non-oxidizing acids had a preservative effect. Formaldehyde, he states, if present in as small amounts as one-tenth of 1 per cent. will destroy the activity of epinephrine in a few hours. According to Rowe (*A. J. P.*, 1914, p. 145), boiling for a period of five minutes produces only an imperceptible amount of change in epinephrine solutions. After three boilings of five minutes each, however, there was a distinct loss of physiological activity.

Solutions of epinephrine are incompatible with oxidizing agents, such as ferric salts, hydrogen peroxide, free alkalies and free halogens. Most reducing agents, such as sulphites, have a preservative effect, but formaldehyde destroys its activity very quickly.

Uses.—Epinephrine stimulates the peripheral endings of the sympathetic nerves. As these nerves carry impulses to practically all of the vital organs it is evident that the injection of the alkaloid into the circulation will cause most wide-spread changes in function. In some cases the sympathetic nerves carry augmentor (motor) impulses, in others they carry inhibitory impulses. In the first case it is manifest that stimulation of these nerves by the epinephrine leads to an exaltation in the function of the organs supplied by them, while in the second instance the stimulation of the inhibitory mechanism will retard function. Hence we find that although epinephrine increases, for example, the contraction of the arterial muscles, it causes relaxation of the intestinal muscles.

It is impossible to consider all the results of this sympathetic stimulation upon the system and the interested reader is referred to H. C. Wood, Jr.'s *Text-book of Pharmacology* for further details. The effects resulting from this action which are of clinical interest are upon the circulation, the uterus and the bronchial musculature.

Because of the stimulation of the sympathetic nerves supplying them, epinephrine causes a violent contraction of the arterial muscles which in turn leads to a great increase in the intra-arterial blood pressure. Accompanying this rise in blood pressure there is usually a marked slowing of the pulse which, however, is probably due largely to the cardio-inhibitory reflex which ordinarily accompanies high blood pressure whatever be its cause.

The injection of large, and especially repeated, doses of epinephrine often causes an increase of the blood sugar and consequent appearance of glucose in the urine. This effect is probably due to an increased liberation of the glycogen in the liver which by some is attributed to the effects of the drug upon the sympathetic nerves.

In 1903, Josué (*C. B. S. B.*, 1903, lv, p. 30) announced that the repeated injection of adrenalin into the rabbit produced a degeneration of the walls of the aorta more or less similar to that seen clinically in atheroma. This effect appears to be due largely to a direct irritant action on the internal coat of the artery, although it is possible that the extremely high blood pressure may be an adjuvant factor. The practical importance of this observation is made questionable by the fact that the arterial changes do not seem to occur in either the dog or cat.

Epinephrine is used in medicine for five distinct purposes: (1) For overcoming local congestions; (2) to check local hemorrhages; (3) as a general circulatory stimulant; (4) for the relief of asthmatic paroxysms, and (5) to cause contraction of the uterus. Each of these requires separate consideration.

While the local application of moderately concentrated solutions of epinephrine in acute inflammatory conditions, such as *conjunctivitis, rhinitis* and the like, will cause an immediate blanching of the part, and often a temporary cessation of the symptoms, it is very questionable if the method of treatment in any way shortens the duration or lessens the real severity of the disease. Sollmann and Brody (*Proc. Soc. for Ex. Biol. and Med.*, 1922, xix, 400) have shown that the local application of adrenalin greatly reduces local resistance to infection by pyogenic organisms in the rabbit. On the other hand in passive congestions—the so-called *chronic inflammations*—it is often a remedy of much service. Thus, in *hay fever,* it produces temporary relief, at least in a very large proportion of cases. In this connection also might be mentioned the use of epinephrine in prolonging and enhancing the action of the local anesthetics. This effect is probably the result of the stoppage in the local circulation.

For *hemorrhages* from regions to which it can be directly applied to the bleeding point, epinephrine is one of the most valuable remedies that we possess. Its action differs essentially from that of the true styptics, in that the latter act chiefly by coagulating the albumen of the blood, and thus leave behind a hard clot, which is often an objectionable feature, while the hemostasis after epinephrine is due solely to its contraction of the blood vessels. When the torn vessel is of large caliber, epinephrine is a less certain remedy than the older styptics. Although it has been largely used internally in the treatment of non-accessible hemorrhages, it is not demonstrated that its influence in these conditions is beneficial. Some ground is afforded for its use in internal hemorrhages by the findings of Cannon and Grey (*A. J. Phys.,* 1914, xxxiv) that small doses accelerate the coagulation of blood. This has been confirmed by Grabfield (*A. J. Phys.,* 1916, xlii).

As a general circulatory stimulant the fugaciousness of the action of epinephrine limits its usefulness to the very acute forms of *circulatory failure,* such as *surgical shock, collapse* during anesthesia, and similar conditions. Although when injected hypodermically its effects are very slight, if thrown into the substance of a muscle (intramuscular injection) a very considerable degree of activity is obtained. Greuel (*B. K. W.,* 1921, lxiii, 1381) recommends that in very alarming conditions the epinephrine be injected directly into the heart and reports 13 cases, including 2 of his own, in which there was complete recovery, after apparent cessation of the heart beat, from this intracardiac injection. Donaldson (*B. M. J.,* 1914, i, p. 476) has shown that five minims of a one to one-thousand solution so injected will produce in normal men a rise in the blood pressure of from 15 to 45 millimeters, and according to Miller (*J. A. M. A.,* 1908) the rise lasts from one-half to three-quarters of an hour. In cases of degeneration of the heart muscle the drug must be used with great caution as the strong vascular constriction throws an intense strain upon the heart. Ulrich and Ripins (*J. P. Ex. T.,* 1922, xix, p. 217) have observed in an apparently healthy man, from the intravenous injection of 5 minims (0.3 cc.) of a one to 1000 solution of epinephrine symptoms so severe that death seemed imminent for several minutes.

In bronchial *asthma* the intramuscular injection of epinephrine will nearly always cause an immediate arrest of the paroxysm. Unfortunately in many instances the relief is only temporary, lasting perhaps an hour or two. According to Ephrain (*D. M. W.,* 1912), however, if the solution is applied directly to the bronchial mucous membrane the effects are much more lasting. When the asthma is dependent upon heart disease it should never be used because the sudden increase in arterial resistance may be sufficient to overcome the resistance of the enfeebled heart; Fredericia (*J. A. M. A.,* Feb. 5, 1916) has reported two deaths following the use of epinephrine for the relief of asthma which had been mistakenly diagnosed as bronchial when really of cardiac origin. In cases where evil effects are feared from the arterial spasm, it is well to guard the drug with nitroglycerin.

When applied either locally or injected internally, epinephrine causes a violent spasm of the uterus. Although, according to Neu (*Archiv. f. Gynekol.,* 1909, lxxv, p. 618), this occurs in the human being either in the pregnant or non-pregnant condition, the drug is not to be recommended for general uterine hemorrhages, but is of great value in the treatment of *post-partum hemorrhages.*

Various preparations containing epinephrine, as well as the alkaloid itself, have been used, with apparent benefit, in the treatment of *osteomalacia* and also *rickets.*

In 1918 Goetsch found that in patients suffering with exophthalmic goiter the hypodermic injection of 0.5 cc. of epinephrine solution (8 minims) caused a series of marked changes in the color of the skin. This has since been used as a diagnostic test for *hyperthyroidism.* It has been shown, however, that although the reaction occurs in the great majority of patients with over-acting thyroid glands it is by no means limited to this condition. For description of the test see Part II under *Diagnostic Tests.*

To obtain its systemic effects epinephrine must be given either intravenously or intramuscularly; ordinary hypodermic injections will not serve the purpose.

The number of proprietary brands of epinephrine on the market is very large. The more important of these include: *Adnephrin, adrenaline, adrenamine, epirenan, hemisine, hemostatin, paranephrin, renalina, supracapsulin, suprarenalin, supranephrane,* and *suprarenin.*

The *dose* of epinephrine is from one two-hundredth to three two-hundredths of a grain (0.0003–0.0009 Gm.) or as commonly expressed from 5 to 15 minims (0.3–1.0 cc.) of the one to one thousand solution.

As a local application, epinephrine may be used in strengths of from 1 in 10,000 up to 1 in 1000.

ERGOTA. U. S., Br.

ERGOT Ergot. [Secale Cornutum, P. I., Ergot of Rye]

"Ergot is the dried sclerotium of *Claviceps purpurea* (Fries) Tulasne (Fam. *Hypocreaceæ*), developed on rye plants. Ergot, in the form of the fluidextract, administered by intramuscular injection to single-comb, white Leghorn cocks, in doses not exceeding 0.5 cc. for each kilogram of body weight of cock, produces a darkening of the comb, corresponding in intensity to that caused by the same dose of a standard fluidextract of ergot, prepared as directed below. It contains not more than 5 per cent. of seeds, fruits or other foreign organic matter. Ergot should be dried at a low temperature. It deteriorates with age and should not be kept longer than one year." *U. S.*

"Ergot is the sclerotium of Claviceps purpurea, *Tulasne,* originating in the ovary of Secale cereale, *Linn.* Ergot should be thoroughly dried and kept entire in air-tight containers; it should not be used if more than one year old." *Br.*

Secale Clavatum, Mater Secalis, Clavus Secalinus; Rye Smut, Mother of Rye, Cockspur Rye; Ergot de Seigle, *Fr. Cod.;* Ergot, Seigle Ergoté (noir), Blé Cornu, *Fr.;* Secale Cornutum, *P. G.;* Mutterkorn, Kornmutter, Rogenmutter, Zapfenkorn, Hungkorn, *G.;* Segala cornuta, Grano speronato, *It.;* Cornezuelo de centeno, *Sp.*

In all the *Gramineæ,* or grass family, and in some of the *Cyperaceæ,* the place of the grains or fruits is sometimes occupied by a morbid growth which, from its resemblance to the spur of a cock, has received the name of *ergot,* adapted from the French. This product is most frequent in the rye, *Secale cereale,* and from that grain was adopted in the first edition of the U. S. Pharmacopœia, under the name of *secale cornutum,* or *spurred rye.* In the edition of 1840 the name was changed to *ergota.*

It is probable that this morbid growth has similar properties from whatever plant derived, and the fact has been proved in relation to the ergot of wheat. Tulasne found that dissimilar sclerotia collected from twelve species of grasses, produced fructification identical with that of the ergot of rye, so that it is probable that many apparently dissimilar ergots are specifically identical, their appearance being modified by the species of grass which they inhabit. It is further probable that all ergots have medicinal properties which agree in character though not in intensity. The short thick ergot which gathers upon the wild rice of Minnesota, *Zizania aquatica* L., has long been used as an abortifacient and oxytocic by the Indian women, and it is said that the wild ergot growing on various species of *Agropyron* and *Elymus* in the western United States, is fully equal medicinally to the official plant. The *Claviceps Paspali,* a fungus growing on a South African grass, has, according to Nutchell (*J. Dept. Agricul.,* South Africa, 1920), given rise to typical ergotism. M. Leperdriel, Jr., affirms that the *ergot of wheat* is destitute of the poisonous properties of that of rye, and is less liable to change. Ergot is rarer in wheat than in rye, and in the head of the former there is generally but one and very rarely more than two of the diseased grains. It is produced usually in wheat in wet seasons, and on that side of the head most exposed to the dampness. It is shorter and much thicker than the ergot of rye, being about half an inch long and three-quarters of an inch or more in circumference, and cleft into two or three divisions. In color and odor it resembles spurred rye.

The *ergot of oats* is said to be of a black color, measuring from ten to twelve millimeters in length and three to four in thickness, and to have been used in Algeria as a substitute for rye ergot. (*L. M. R.,* March, 1888.) Warburton (*Bot. Gaz.,* 1911, p. 64) reports the occurrence of ergot on oats grown in the oat breeding nursery at Ames, Iowa. The *ergot of diss* (an Algerian reed, *Ampelodesma tenax*) has appeared in commerce to some extent. It is, when small, slightly curved, but when long (6 to 9 centimeters) it takes a spiral turn from right to left, the longitudinal furrows being present on the inner face. It is thinner, dryer, and more brittle than the ergot of rye, and has been used for the preparation of an ergotine or extract closely resembling the official one, but said to be of a more translucent red or brown color. Lallemand asserts that the ergot of diss is twice as strong as the ergot of rye, and states that it is abundant and readily collected. It is also stated to be less hygroscopic and less apt to be attacked by acari than is the official article. (*P. J.,* xvi, 684, 1886.)

Investigations of Tulasne have shown that ergot represents the *sclerotium* of a fungus, *Claviceps purpurea* Tulasne. This fungus has three stages in its life history which is as follows:

In the spring or early summer the spores of this fungus are conveyed by insects or air-currents to the young developing ovaries of the rye. At the base of each ovary—where moisture occurs during damp weather—they germinate into filamentous hyphæ which penetrate the tissues by enzymic action. From here the hyphal filaments spread over the pistil enveloping it except at the summit and penetrating its outer coat. During all this time the hyphæ secrete enzymes which decompose the outer tissues of the ovary into a white, caseous mass called the sphacelia. The ovary enlarges and its upper end takes on a spongy appearance. This is due to the projection of twisted strands of hyphæ which here abstrict off chains of oval conidiospores. A yellow mucoid, saccharine exudate, issuing from the hyphæ and called *honey dew,* now envelops the conidiospores. The honey dew attracts ants, flies, weevils, etc., which carry the spores to the ovaries of other spikes of grain, so disseminating the disease. This terminates the sphacelia stage. At the base of the sphacelia and later extending upward through the ovarian substance, the hyphal threads penetrate deeper and deeper into the interior of the ovary consuming its substance until there ultimately forms a dense, compact tissue (pseudoparenchyma), violet black without and whitish within, that eventually replaces the developing grain with a violet or purplish curved body known as the sclerotium. This structure represents the resting or sclerotial stage in the life history of *Claviceps* and is collected as the official ergot.

The ergot which is not collected falls to the ground where, the following spring, it absorbs moisture and sprouts into several stalked projections terminated by globular heads which are called ascocarps or stromata. Each head develops in its peripheral parts flask-shaped invaginations called *perithecia.* From the base of each perithecium several sacs or asci develop. Within each of the latter there originate eight thread-like spores called ascospores. When these are mature the ascus ruptures and the ascospores are discharged. They are carried by air-currents to fields of gain, there to infect young ovaries and begin new life cycles.

Ergot has absolutely nothing in common with normal grain. The anatomical structure and all the physical characters of ergot are those of a sclerotic mycelium. The pseudoparenchyma, which is whitish, dry, and brittle, consists in all its parts of irregular, globular, or polyhedric thick-walled cells, intimately united, and filled with a limpid oil, but feebly colored by iodine. The superficial utricles, which alone are colored, have an outer wall thicker than the inner, and the color of these is what gives its characteristic hue to ergot. Not the least trace of starch is to be detected. If ergot is planted in a suitable soil, evidences of germination are seen in about three months. L. Hecke has recently produced artificial infection of rye flowers by spreading them with a suspension of conidiospores in water. The ergot grains (sclerotia), which were sown in autumn in boxes of earth and exposed to the frosts of winter, germinated in the spring, producing ascocarps which liberated ascospores. These were found to quickly germinate on nutritive gelatin and when transferred to suitable media produced large numbers of conidiospores (conidia). (*Schweiz. Apoth. Ztg.,* 1921, lix, 277.) The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the place of the seeds is wholly occupied by the ergot, in others only two or three spurs are observed. It is said to be much more energetic when collected before than after harvest. Rye has generally been thought to be most subject to the disease in poor and wet soils, and in rainy seasons, and intense heat succeeding continued rains has been said to favor its development, especially if these circumstances occur at the time the flower is forming. It is now, however, asserted that moisture has little or nothing to do with its production.

Ergot is gathered in Spain, Galicia, Russia, Austria and Germany, being either picked by hand or thrashed and separated from the rye by special machinery. It enters commerce chiefly from Russia, Germany, and Spain. Of the three varieties the Spanish ergot is considered the best, yielding usually from 13 to 15, sometimes as high as 18, per cent. of extractive. It is somewhat darker colored, rather shorter, and more uniform than is the German ergot. An ergot of excellent quality has been sent from the Canary Islands to England.

Description and Physical Properties.—"*Unground Ergot*—Cylindraceous, obscurely 3-angled, tapering towards both ends, obtuse, somewhat curved, from 1 to 4.5 cm. in length and from 3 to 5 mm. thick, longitudinally furrowed; extremely dark purple or dark reddish-brown; fracture short; internally white, tinged with purple or gray; odor characteristic but free from mustiness or rancidity; taste oily, somewhat acrid, disagreeable.

"*Structure.*—A thin outer portion of small compact cells generally deep violet in color, turning red with 50 per cent sulphuric acid or with chloral hydrate T.S.; the inner portion, simulating parenchyma tissue, of thin-walled, colorless cells usually less than 0.015 mm. wide, but slightly elongated and containing numerous globules of fixed oil.

"*Powdered Ergot*—Grayish to purplish-brown; containing purplish and whitish fragments of the outer tissue and of the thin-walled cells.

"Shake 1 Gm. of powdered Ergot in a closed flask for about five minutes with 20 cc. of ether and about 15 drops of 20 per cent. sulphuric acid. Filter, and shake the filtrate thoroughly with 15 drops of a cold, saturated sodium bicarbonate solution. The separated lower aqueous layer is red or violet (*sclererythrin*). When crushed or powdered, Ergot does not develop a rancid or ammoniacal odor upon the addition of hot water." *U. S.*

"Subcylindrical or somewhat triangular, tapering towards the ends, generally curved; from one and a half to four centimetres long; longitudinally furrowed on each side, but more especially on that which is concave; often irregularly cracked; very dark violet-black externally, whitish or pinkish-white within; fracture short. Odor characteristic and disagreeable, especially when triturated with *solution of sodium hydroxide;* taste disagreeable." *Br.*

The aqueous infusion or decoction is claret-colored, and has an acid reaction. It is precipitated by lead acetate and subacetate, silver nitrate, and tincture of galls, but affords with iodine no evidence of the presence of starch.

The U. S. and the British Pharmacopœias state that ergot should not be kept for more than a year. While there is not sufficient data to allow of positive conclusions, Wood and Hofer (*A. In. M.,* 1910, vi, 388) found that in a sample carefully dried and sealed the activity was not perceptibly diminished after six months, and Eberhardt and Eldred (*J. A. Ph. A.,* 1914, iii, 38) quote Moss as having shown that, freed from its oil, ergot will retain its virtues unimpaired for two and even five years. (For discussion of the deterioration of the *Fluidextract of Ergot,* see p. 496.) The germinating test has been utilized in determining a good quality of ergot and Zimmermann (*Ztschr. f. Pflanzen-*

krankheiten, 1907, p. 129) concludes that the sclerotium of *Claviceps purpurea* is capable of germinating even after keeping for two years. Ergot sometimes contains small stones and cereal grains, implying that it has not been carefully garbled. Many samples are "wormy," some really being alive with insects. Old ergot is sometimes brightened by the use of a fixed oil; the revisers of Vienna Pharmacies (*Pharm. Prax.,* 1905, p. 38) reported finding one sample of powdered ergot which contained flour as an adulterant.

Ergot, when perfectly dry and kept in well-stoppered bottles, will retain its virtues for a considerable time, but exposed to air and moisture it speedily undergoes chemical change and deteriorates. It is, moreover, apt to be attacked by a minute worm, which consumes the interior of the grain, leaving the exterior shell and an excrementitious powder. This insect is sometimes found in the ergot before removal from the plant. Camphor and powdered benzoin are said to prevent injury from worms. Aymoiner immerses fresh ergot in an ethereal solution of tolu, dries it, and preserves in tightly closed bottles.

Constituents.—Ergot is an extremely complexed body containing a number of bases—to which its physiological properties are due—, a peculiar semi-cellulose called mannan, which yields on hydrolysis mannose, and probably one or more resinous acids.

Tschirch classifies the basic substances of ergot into three groups: "(A) *Initial* bases, *Ergotine, ergotoxine* (hydroergotinine), vernine and *ergothioneine.* (B) *Intermediate* bases, (1) acyclic: (Arginine, not isolated), agmatine, leucine, isoamylamine, choline, betaine; (2) with cyclic nucleus: (Tyrosine, not isolated), tyramine, uracil; (histidine, not isolated), histamine; (3) of unknown constitution; cornutine, clavine, sphacelic acid, ergotic acid. (C) *Decomposition end products of B,* among these cadaverine, putrescine, aniline, trimethylamine and methylamine."

Of the above named bases *cornutine,* which was first described by Kobert (*Ph. Centralh.,* 1884, p. 607) is regarded as an artefact not occurring naturally in ergot. Although a poisonous substance, it is improbable that ergot in any part owes its activity to this alkaloid. The cornutine of Keller is a very different substance and appears to represent all of the alkaloidal bodies present in the crude drug.

Ergotinine, $C_{35}H_{39}O_5N_5$, which was first described by Tanret (*P. J.,* 1885, p. 889), is a crystallizable, colorless alkaloid, and is probably identical with Wenzell's *ergotine.* The solutions of ergotinine turn greenish and red very soon; they are fluorescent. Sulphuric acid imparts to it a red, violet, and finally blue, hue. It is physiologically inert. A second alkaloid was discovered almost simultaneously by Barger and Carr, and by Kraft (*A. Pharm.,* 1906), the former calling it *ergotoxine,* and the latter *hydro-ergotinine.* Barger and Carr (*Tr. Chem. Soc.,* 1907, xci, 337) have shown that ergotoxine has the formula $C_{35}H_{41}O_6N_5$, and agree with Kraft that it is the anhydride of ergotoxine. Ergotoxine may be changed into ergotinine by boiling with methyl alcohol or acetic anhydride. *Sphacelotoxin,* described by Jacoby, is a substance having acid properties contaminated with ergotoxin; Wood and Hofer believe that the acid and the alkaloid are in chemical combination. The activity of ergot seems to be due chiefly to the alkaloid ergotoxine, but the effect of this is more or less modified by the putrefactive amines which are present. Of these amines there have been so far separated *para-phenylhydroxylamine* (also known as *tyramine* or *uteramine*), and *beta-iminazolethylamine* (*histamine, ergamine, imidazol*).

Aminosecalo-sulphonic acid, $NH_2.C_{15}H_{27}O_{15}$-SO_3H, is identical with *ergotic* acid of Kobert and is physiologically inert. *Clavine* has been shown by Barger and Dale to be a mixture of leucine and aspartic acid. Ewins (*Biochem. J.,* 1914, viii, p. 44) has shown the occurrence in certain specimens of ergot of *acetyl-choline* which is a powerful circulatory depressant, and more or less antagonistic to the other principles of ergot.

In 1921 Spiro and Stoll (*Schweiz. Apoth. Zeit.,* 1922, lx, 341) isolated what they believe to be a new alkaloid which they called ergotamine and assign the formula $C_{35}H_{35}O_5N_5$. Dale and Spiro (*A. E. P. P.,* 1922, xcv, 337), however, showed that the actions of this alkaloid are identical with those of ergotoxine.

Carr and Dale (*W. Br. Ph. Conf.,* 1913, 505) state that as *ergotoxine* is the recognized active principle of ergot the value of ergot and its preparations should be judged by the content of that principle. They also recognize the supplementary value of the amines, such as *ergamine,* and state that, given equal ergotoxine values, the sample which is higher in amines will be therapeutically superior. They commend the U. S. P. fluidextract as being a preparation of great value.

According to T. R. Baker, the ergot oil has a taste and odor similar to those of castor oil, with which it also agrees in ultimate composition, and yields analagous results in saponification. T. C. Herrmann investigated specially the chemical constitution of the oil of ergot. As obtained by means of ether, it was brownish-yellow, of an aromatic odor and acrid taste, viscid, of the sp. gr. 0.9249, and without any drying property. It consists of 22.703 per cent. of palmitic acid, 69.205 of oleic acid, and 8.091 of glycerin. (*N. R.,* 1872, p. 238.) The *sugar of ergot* was found by Mitscherlich to be *mycose,* $C_{12}H_{22}O_{11}$.

Assay.—The great variation in the potency of different samples of ergot, as well as its practical importance, has led to a number of attempts to develop means of determining the quality of the drug. These efforts have included both the chemical and the biological assay.

The earliest systematic use of the biological reaction for determining the quality of ergot were the experiments of Grünfeld in 1895. His method was based upon the quantity of the sample which was necessary to cause gangrene in the combs and wattles of roosters, and is commonly spoken of as the *cock's comb method*. This test was later utilized by Houghton (*T. G.*, 1898) on a commercial scale and is now official.

"Use single-comb, white Leghorn cocks, which are less than eighteen months of age, and weigh approximately 2 kilograms. Injections are made deeply into the breast muscles, and the effects are observed within one hour to one hour and a half after the administration of the drug. The same cock must not be used for testing purposes at shorter intervals than two weeks." *U. S.*

The criterion of the cock's comb method is the dose of a sample of ergot which is required to cause a bluing of the comb. It is important that the same breed of chickens be used throughout any series of experiments; white Leghorns are generally preferred. The method is carried out as follows: A rooster is weighed, and then a dose of the fluidextract to be tested, equivalent to about 1 cc. (16 minims) per kilogramme of body weight, is injected into the muscle of the breast. An hour later the bird is examined. If the specimen has been an active one, there will be a bluish or cyanotic appearance around the edge of the comb. The extent and degree of this discoloration is compared with that caused by a standard preparation in the same chicken on another day. The same rooster may be used over and over again, and the experimenter soon learns the degree of bluing which is the characteristic reaction of that individual chicken for a standard dose of active drug. If no bluing occurs the drug is below the standard.

In order to have some standard of comparison for this test the U. S. has recognized a *Standard Fluidextract of Ergot* which is prepared as follows:

"Prepare a composite fluidextract, representing at least ten different lots of Ergot, conforming to the official botanical description. This standard fluidextract, which must be aged for at least six months before being standardized by the method described in the preceding paragraph, and must be preserved in a vacuum, when administered by intramuscular injection in doses not exceeding 0.5 cc. per kilogram of body weight of cock, produces darkening of the comb of a single-comb, white Leghorn cock which is less than eighteen months of age, and which weighs approximately 2 kilograms.

"Preserve in air-tight containers." *U. S.*

The U. S. Bureau of Chemistry will furnish such a standard to manufacturers.

The idea of using the elevation of blood pressure for the assay of ergot seems to have been first suggested by Dixon (*P. J.*, 1905), and was elaborated by Wood and Hofer. (*A. In. M.*, 1910, vi, 388.) The method as employed by the latter is as follows: A dog is anesthetized with morphine and ether, and the carotid artery connected with a mercurial manometer. The normal blood pressure is observed, and then a dose of the sample equivalent to 0.15 Gm. of ergot for each kilo of body weight is injected intravenously, and the blood pressure noted (1) at its highest point after the injection, (2) five minutes after, and (3) ten minutes after the injection, the average elevation above the norm of these three observations represents the physiological activity of the specimen. In order to obviate peculiar susceptibility in individual dogs, it is necessary that experiments be made upon three animals with each sample. Edmunds and Hale modified the method by previously administering atropine for the purpose of avoiding the stimulant action upon the vagus, but their results were less consistent than those who have worked on the normal animal. The two objections which have been urged against this method are, in the first place, the assertion that because the drug is used chiefly as a uterine stimulant, a blood pressure test does not give satisfactory criterion of the therapeutic activity of the drug, and secondly, the possibility of a market abnormality in the reaction of one of the experimental animals creating a false idea of the activity of the drug. An attempt has been made to obviate this last objection by comparing the effects of a standard specimen upon the same animal.

The objection that since the drug is used chiefly as a uterine stimulant, the blood pressure test is not a satisfactory criterion of its therapeutic activity, must not be given too great stress. Stewart and Pittinger (*Trans. of the Amer. Therap. Soc.*, 1914) have shown that there is a close parallelism between the degree of action of various samples of ergot upon the blood pressure and upon the uterus.

Two methods in which the uterine muscle is used as an indicator of ergot have been suggested, that of Kehrer (*A. E. P. P.*, 1908, lviii) in which the uterus is removed from the body and either strips of the isolated muscle or the whole organ are employed, and that of Edmunds in which the uterus *in situ* furnishes the test reaction.

The first of these methods is the same as that now official for standardizing of pituitary solution (see *Liquor Pituitarii*) except that the drug should be compared with a standard fluidextract of ergot.

Pittinger and Vanderkleed (*J. A. Ph. A.*, 1914, iii, p. 925) have modified this method by adding weights until the uterus is barely able to move the lever and testing the strength of the muscle against this added resistance.

The method employed by Edmunds (*Hygienic Lab. Bul.*, No. 76, July, 1911) is most satisfactorily performed upon cats. The anesthetized animal, which is kept alive by artificial respiration throughout the experiment, is immersed in a bath of physiological salt solution at a temperature of 39° C., the abdomen is then opened by a medium incision, the bladder and intestines drawn aside; one horn of the exposed uterus freed by tearing away the peritoneal attachments and two fine silk threads passed through this horn at a distance of about two centimeters apart. These threads are then connected to a light muscle lever. To obtain the proper degree of tension weights may be added to the muscle lever. The ergot to be tested is then injected intravenously alternating with a standard solution. As in this method there is no definite end reaction it is often difficult to judge of the relative potency of the two preparations. Edmunds and Hale themselves say of it: "It is not an unusual experience to carry on such an experiment for two or three hours and . . . . to know very little more about the relative strengths of the two specimens at the end than at the beginning of the experiment."

There are several practical objections to all the uterine methods of assay. In the first place, they require a greater degree of technical skill in carrying out than either the blood pressure or cock's comb methods; in the second place, there is no definite end-point of the reaction so that it is difficult to make quantitative comparisons; and in the third place, the uteri of different species of animals do not respond in the same way to the drug, and even in the same species the effect may vary. Thus Dale finds that isolated strips of uterine muscle from the guinea-pig respond to ergotoxine but similar strips from the cat do not, although the intact uterus from the latter animal is excited by this alkaloid; tyramine causes contraction of the uterus in the pregnant and relaxation in the virgin cat. Brown and Clark (*J. P. Ex. T.,* 1923, xxi, p. 59) criticize the Edmunds method on the ground that it is in large degree a measure of the amine content which is of small therapeutic importance. They suggest another test based on the fact that the ergot alkaloids when applied to isolated strips of uterine muscle in sufficient concentration destroys the response of the muscle to epinephrine.

There has been much discussion as to which method is the most useful for standardizing ergot. For commercial purposes at least the choice lies between the cock's comb and the blood pressure method. The former has the great advantage of its simplicity, but it has the disadvantage of the absence of a sharp end reaction, for the change in the color of the comb may vary anywhere from an almost imperceptible darkening of the tip to a deep cyanotic color of the whole appendage—and hence leaves a wider range for possible personal error. As the different principles of ergot produce different physiological effects, it is evident that the two tests may give very different results for the same specimen of ergot; thus ergotoxine causes both bluing of the comb and rise in blood pressure; while tyramine causes rise in blood pressure but no bluing, while histamine causes no rise in blood pressure but, according to Crawford and Crawford (*J. A. M. A.,* 1913, lxi), it does cause bluing of the comb. For reasons pointed out by Crawford and Crawford, it is improbable that the fluidextract of ergot, prepared according to the U. S. P., will contain any considerable proportion of histamine, and it would seem, therefore, that a blood pressure method would furnish more accurate information concerning the American fluidextract than the test upon the rooster. But it must be remembered that the proper performance of the blood pressure test requires more technical skill than that upon the rooster, and in the hands of the unpractised it is probable that the cock's comb method would yield more favorable results.

The reader who is interested in this subject may find extensive references to the literature in the paper of Wood and Hofer (*A. In. M.,* 1910, iv, p. 388) and of Edmunds and Hale (*U. S. Hygienic Laboratory Bull.,* No. 76, 1911).

Pearson (*J. A. Ph. A.,* 1913, ii, p. 1453) reports upon the tests of the activity of ergot by the blood pressure method. Heated on a water bath for thirty minutes the fluidextract of ergot loses almost completely its power of raising the blood pressure. Evaporating at room temperature by a current of air does not destroy its activity. Extract of ergot (U. S. P.) had practically no effect on blood pressure. Bonjean's ergotin produced no rise and usually a decided fall in pressure. A powdered extract (method of manufacture not given) produced a temporary rise but the increased pressure was not sustained.

Uses.—The three bases of ergot, while differing in their physiological actions, unite in increasing the contractions of the pregnant uterus. Ergotoxine is a stimulant to all the involuntary muscles including the heart, the arteries and the intestines, as well as the uterus; it, therefore, increases blood pressure and intestinal peristalsis. Histamine has a similar effect to ergotoxine upon muscle fibers but differs in that it has a specific action upon the vasomotor center and tends to dilate instead of contracting the arterial muscles and also in the fugaciousness of its effects; it tends to lower rather than increase blood pressure. Tyramine is a stimulant to the sympathetic nerve endings closely resembling epinephrine in its actions; the involuntary muscles are either excited or inhibited according to the character of impulses conveyed by the sympathetic nerves. Like ergotoxine it tends to increase the blood pressure but its action is much quicker and of comparatively short duration.

When a dose of ergot is injected intravenously there occurs a rise in the blood pressure, sometimes preceded by a transient fall, and accompanied with a reduction in the rate of the pulse. The elevation of the pressure is due in part to a contraction of the blood vessels, the result of a direct stimulant action upon their muscular coats, but also in part to a stimulating effect upon the cardiac muscle. The effect of a small dose of ergot upon the uterus is to increase both the vigor of its contraction, and its muscular tone. If the dose is larger, the increase in muscle tone becomes relatively more and more pronounced, until eventually the organ may be thrown into a permanent spasmodic contraction.

On the continent of Europe ergot has long been empirically employed by midwives for promoting contraction of the uterus, and its German name "Mutterkorn" implies the popular acceptance of its peculiar powers, but it was first introduced to the regular medical profession as the result of the writings of Stearns. (*N. Y. Medical Repository,* 1807.) While a remedy of undoubted utility in properly selected cases of *labor,* its injudicious use may do much harm, and even prove fatal to either the mother or the child. When used freely, ergot is liable to transform the normal intermittent contractions of the parturient uterus into one violent spasm. If this spasmodic contraction occurs too early in the course of the birth process it may lead to asphyxiation of the child, to wide lacerations of the birth canal, or even to rupture of the uterus. In the third stage of labor, however, no such accidents can occur, and many obstetricians recommend the routine use of ergot at this time, as a prophylactic against *post partum hemorrhage.* Ergot is also used as a stimulant to the non-pregnant uterus to check bleeding in *menorrhagias* and *metrorrhagias.*

As a circulatory stimulant, ergot deserves more popularity than it has received. Although certain authors have found it a serviceable remedy in acute circulatory failure, such as *surgical shock,* the slowness of its action interferes with its utility in this condition, and its most important field of usefulness is in chronic vasomotor relaxations. Thus, it is useful in cerebral or *spinal congestion,* in *colliquative sweats,* in relaxing *diarrhea,* and similar conditions in which there are local passive congestions. Because of its success in hemorrhage from the uterus, ergot has been widely employed in various other internal *hemorrhages,* but its value under these circumstances is doubtful. Probably because of the effects of ergot on the circulation it is a very valuable remedy in the treatment of *delirium tremens.* (See Ransom and Scott, *A. J. M. S.,* 1911, cxli, p. 673.) Osborne (*N. Y. M. R.,* July 14, 1906) says that it has a powerful sedative effect upon the central nervous system and is useful in certain types of *asthma,* in *Graves's disease, hysteria,* and especially for the nervousness in the withdrawal of morphine.

Under the name of "ergotin," usually with the name of the maker attached, a number of more or less purified extracts of ergot are upon the market. The doses of these range from one to ten grains according to their purity. *Bonjean's ergotin* is made by exhausting ergot with water, evaporating to the consistency of syrup, precipitating the albumen, gum, etc., with alcohol, decanting the clear liquid and evaporating to the consistency of the soft extract. It is to be remembered in this connection that no aqueous extract of ergot can thoroughly represent the crude drug. *Ergotoxine* is marketed in the form of a crystalline phosphate, the dose of which is from one one-hundredth to one-fiftieth of a grain (0.0006–0.0013 Gm.). The hydrochloride of para-hydroxyphenylethylamine is sold under the trade name of *tyramine.* Hewlett (*A. I. M.,* 1918, xxi, 411) has found that it causes a rise of blood pressure and increased output of the heart, in human beings, in doses of 0.030–0.080 Gm. (½ to 1¼ grains).

The most widely used unofficial preparations of ergot are as follows:

Ergotin Bonjean (see *Extractum Ergotæ Aquosum,* Part III).—*Dose,* three to eight grains (0.2–0.5 Gm.).

Ergotin Wernich Merck.—Purified, dried, dialyzed aqueous extract of ergot. *Dose,* twenty grains (1.3 Gm.).

Ergotin Wiggers.—Dose, ten to fifteen minims (0.6–0.9 cc.).

Ergotole.—Dose, five to twenty minims (0.3–1.3 cc.).

Ernutin.—Dose, five to ten minims (0.3–0.6 cc.).

Ergone.—Dose, fifteen to thirty minims (0.9–1.8 cc.).

Cornutol (*Liquid Extractum Ergotæ*).—*Dose,* ten to thirty minims (0.6–1.8 cc.).

Clavin.—Dose, one-third of a grain (0.02 Gm.).

Femergen is asserted to be ergotamine tartrate.

Toxicology.—Ergot can scarcely be considered as a poison, since an ounce of the fluidextract rarely produces, except in the pregnant, any obvious symptoms unless it be nausea. Large doses are liable, it is true, to produce abortion in pregnant women, but even this result is uncertain. We know of but one instance of fatal poisoning by it, unless the death was produced by the abortion. The symptoms of the recorded cases of poisoning have been paleness, and, as most characteristic, an especial coldness of the surface, partial paralysis with numbness and tingling in the limbs, feebleness of the pulse, restlessness, and finally stupor or delirium.

On the other hand, the long continued and free use of ergot is highly dangerous, even when no immediate effects are perceptible. Fatal epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this fungus. Dry gangrene, and disorder of the nervous system attended with convulsions, are the forms of disease which have followed the use of this unwholesome food. It is true that ergot has been denied to be the cause, but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with experiments upon inferior animals, leave no room for reasonable doubt that at least the gangrenous affection alluded to has resulted from it.

Dose, of ergot, fifteen to sixty grains (1–3.9 Gm.).

ERIODICTYON. U. S.

ERIODICTYON Eriodict. [Yerba Santa]

"Eriodictyon is the dried leaf of *Eriodictyon californicum* (Hooker et Arnott) Greene (Fam. *Hydrophyllaceæ*). Eriodictyon contains not more than 5 per cent. of its stems or more than 2 per cent. of other foreign organic matter." *U. S.*

Mountain Balm, Consumptive's Weed, Bear's Weed, Gum Bush; Eriodictyon, *G.;* Feuilles d'Eriodictyon, *Fr.*

Eriodictyon californicum is a low evergreen shrub growing abundantly upon dry hills in California. It is glabrous, resinous, having alternate, short petiolate, long lanceolate leaves, irregularly more or less serrate, whitened beneath, between the reticulations, by a minute and close tomentum, above glabrous. The corolla is tubular funnel-form, violet or white in color; the calyx being sparsely hirsute. The fruit is a 2-celled capsule. The leaf structure has been studied by F. W. Ritter. (See *A. J. P.*, 1895, 565.) The commercial supplies of Eriodictyon come from California.

E. tomentosum, which grows often along with *E. californicum,* especially in the southern part of California, is readily distinguished by its dense coat of short villous hairs, whitish or rusty-colored with age. It is also a larger shrub than *E. californicum,* has its corolla somewhat salver-form, and its leaves oblong or oval, and obtuse.

Description and Physical Properties.—"*Unground Eriodictyon.*—Usually in fragments; when entire, lanceolate, from 5 to 15 cm. in length and from 1 to 3 cm. in breadth; apex acute; base slightly tapering into a short petiole; margin irregularly serrate or crenate-dentate; upper surface yellowish-brown, covered with a more or less glistening resin; under surface grayish- or yellowish- white, conspicuously reticulate with greenish-yellow veins and minutely tomentose between the reticulations; thick, brittle, odor aromatic; taste balsamic, bitter, becoming sweetish.

"*Structure.*—Upper epidermis with large cells, the outer walls very uneven, owing to indentations which appear as striations in surface view, glandular hairs numerous; palisade cells very narrow, from 2 to 6 rows deep; cells of loose mesophyll forming but a few layers; vascular tissues not strongly developed except in the midrib and more prominent veins; numerous non-glandular hairs occurring on the lower surface between the veins.

"*Powdered Eriodictyon.* — Greenish; non-glandular hairs 1-celled, undulate and with thick walls; glandular hairs with 1-celled stalk and 6- to 8-celled heads, the latter up to 0.075 mm. in diameter; tracheæ with spiral thickenings or simple pores and associated with lignified fibers; starch grains few, from 0.003 to 0.020 mm. in diameter; calcium oxalate crystals numerous, in rosette aggregates from 0.005 to 0.030 mm. in diameter." *U. S.*

Tunmann (*Ph. Centralh.,* 1908, p. 159) describes and illustrates the pharmacognostic and microscopic characteristics of *Eriodictyon californicum,* and discusses the morphological importance of the oil glands of eriodictyon.

According to the analysis of Chas. Mohr (*A. J. P.*, 1879, 549), it contains tannic acid and 8 per cent. of an acrid, bitter resin, upon which its activity is believed to depend, also a minute quantity of volatile oil. Thal (*Ph. Z. R.*, 1883, p. 209) affirmed the presence of *ericolin,* $C_{34}H_{56}O_{21}$. Power and Tutin (*Proc. A. Ph. A.*, 1906) deny that ericolin is present but find besides volatile oil and resin, *triacontane,* $C_{30}H_{62}$, *penta triacontane,* $C_{35}H_{72}$, *eriodictyol,* $C_{15}H_{12}O_6$, *homoeriodictyol,* $C_{16}H_{14}O_6$, and an unidentified phenol, $C_{16}H_{41}O_6$. (See also Tutin, *Tr. Chem. Soc.*, 1910, xcvii, 2054.)

Uses.—Eriodictyon has long been used in California as a bitter tonic, and also as a stimulant balsamic expectorant. There is considerable testimony to its usefulness in *asthma, chronic bronchitis,* and allied conditions; also in chronic inflammation of the genito-urinary tract. Attention has been called by Kier to its remarkable power of disguising the taste of quinine, and Meyer (*Ph. Ztg.*, 1905) found that it will also mitigate the unpleasantness of hydrastis or aspidium. It is best exhibited in the form of the official fluidextract, the dose of which is one-half to one fluidrachm (1.8–3.75 cc.); a solid extract has been made, which may be given in doses of from five to fifteen grains (0.32–1.0 Gm.). In cases of asthma, eriodictyon is often used by smoking. The aromatic syrup is well adapted as a vehicle for quinine.

Dose, fifteen to sixty grains (1.0–3.9 Gm.).

Off. Prep.—Fluidextractum Eriodictyi, *U. S.;* Elixir Eriodictyi Aromaticum (from Fluidextract), *N. F.;* Syrupus Eriodictyi Aromaticus (from Fluidextract), *N. F.*

EUCAINÆ HYDROCHLORIDUM. U. S.

EUCAINE HYDROCHLORIDE Eucain. Hydrochl. [Betaeucainæ Hydrochloridum, U. S. P. IX]

"Eucaine Hydrochloride, when dried to constant weight at 100° C., contains not less than 99 per cent. of $C_5H_7N(CH_3)_3O(C_6H_5CO).HCl$." *U. S.*

This derivative of piperidine is made by acting on diacetonamine with paraldehyde and metallic sodium. The product is treated with benzoyl chloride and the trimethyl-benzoxypiperidine, which is formed, is neutralized with hydrochloric acid and the resulting crystals are purified.

Description and Physical Properties.—"A white, odorless, crystalline powder. It is stable in the air. One Gm. of Eucaine Hydrochloride is soluble in 30 cc. of water, 35 cc. of alcohol, and in 6 cc. of chloroform, at 25° C. It is more soluble in boiling water and in boiling alcohol.

"Dissolve about 0.1 Gm. of the salt in 1 cc. of sulphuric acid. Keep the solution at 100° C. for five minutes, and then mix it cautiously with 2 cc. of water; the aromatic odor of methyl benzoate becomes noticeable and on cooling crystals of benzoic acid form. Ten cc. portions of its saturated aqueous solution yield a white, curdy precipitate on the addition of mercuric chloride T.S., and a yellowish, curdy precipitate with a few drops of a mixture of equal volumes of potassium chromate T.S. and diluted sulphuric acid. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 100) a white precipitate which is insoluble in nitric acid.

"An aqueous solution of Eucaine Hydrochloride (1 in 50) is neutral to litmus paper. The ash from 0.5 Gm. is negligible. A solution of 0.1 Gm. of Eucaine Hydrochloride in 1 cc. of sulphuric acid is colorless (*readily carbonizable substances*). Triturate about 0.05 Gm. of the salt with about five times its weight of mild mercurous chloride, and moisten the mixture with a few drops of water; no black color is produced (*difference from cocaine hydrochloride*). No permanent precipitate is produced by the addition of 5 cc. of mercuric chloride T.S. to 5 cc. of an aqueous solution of the salt (1 in 100) (*cocaine and alphaeucaine*)." *U. S.*

Assay.—"Dissolve about 0.5 Gm. of Eucaine Hydrochloride, previously dried to constant weight at 100° C. and accurately weighed, in 100 cc. of neutral alcohol. Titrate this alcoholic solution with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal sodium hydroxide corresponds to 0.02837 Gm. of $C_5H_7N(CH_3)_3O$-$(C_6H_5CO).HCl$." *U. S.*

Uses.—Eucaine is used solely as a local anesthetic. It differs from cocaine in that it is not stimulant to the central nervous system, that it does not dilate the pupil nor contract the blood vessels. Moreover, it is free from the danger of habit formation which is always such an imminent evil with cocaine; and, although at first included in the Harrison Anti-narcotic Law as a restricted drug, the Department has ruled that it is no longer subject to the provisions of the Act.

Although according to the experiments of Eggleston and Hatcher (*J. P. Ex. T.*, 1919, xiii, p. 433) by intravenous injection eucaine has approximately the same toxicity as that of cocaine, when given hypodermically it is very much less poisonous. According to Closson (*J. Mich. State Med. Soc.*, 1914, xiii, 587) the lethal dose for the guinea-pig, by subcutaneous injection, is about eight times as large as that of cocaine, but other experimenters have estimated its toxicity at from one-fourth to one-sixth that of cocaine. It is, however, distinctly less powerful in its anesthetizing action. According to Sollmann (*J. A. M. A.*, 1918, lxx, p. 216), it requires double the strength of eucaine to produce the same degree of anesthetizing effect as of cocaine. Compared to procaine, which it more closely resembles, Sollmann finds that eucaine is inferior in power for injection anesthesia but is superior when applied over mucous membranes. As a local anesthetic it may be used in strengths of from 1 to 5 per cent. It is not used internally except for its anesthetic action upon the stomach in cases of *gastric ulcer*, or other painful conditions of the stomach. For this purpose from one-half to two grains (0.032–0.13 Gm.) may be given at a *dose*.

EUCALYPTI GUMMI. N. F. (Br.)

EUCALYPTUS GUM Eucalypt. Gum. [Red Gum]

"Eucalyptus Gum is a dried gummy exudation from *Eucalyptus rostrata* Schlecht. and other species of *Eucalyptus* (Fam. *Myrtaceæ*)." *N. F.*

"Eucalyptus Kino is an exudation from the stem of various species of Eucalyptus." *Br.*

Kino Eucalypti, *Br.*; Eucalyptus Kino; Australian Kino.

McGookin and Heilbron (*J. P. Ex. T.*, 1926, xxvi, 421 give a list of over 50 species of Eucalypts which yield kino, but most of the commercial article is prepared from *E. rostrata* Schlecht., a common tree in western Australia. This tree received its name from the rostrate character of the opercula. Masses of kino are sometimes found in cavities between the wood and the bark, this being due to the evaporation of the sap in these places. It is usually obtained by incising the trees and collecting the exuding liquid; this, on boiling, yields a solid dark mass which, being friable, breaks up into small dark fragments. The drug is shipped from Melbourne and Victoria to England from which small amounts are imported into the United States. Occasionally the juice reaches England unevaporated. *Kino juice* has a fine deep red color, a slightly aromatic odor, and a decidedly astringent taste, and on evaporation yields a genuine kino in varying amount. It must not be confounded with the so-called *Liquid Kino*, which is obtained from incisions in the *Angophora intermedia* DC. (Fam. *Myrtaceæ*) or kino gum-myrtle of Australia. This varies from the consistency and colorlessness of water to an orange brown or reddish-brown liquid as thick as molasses. It contains catechin and tannic acid, and is said to be especially employed for the purposes of tanning nets.

Description and Physical Properties.—"*Unground Eucalyptus Gum.*—In dark reddish brown grains or angular masses which in thin layers are of a transparent ruby-red color; brittle, the older surfaces sometimes dusty; forming a plastic mass and adhering to the teeth when chewed, coloring the saliva red; taste very astringent; odor slight.

"*Powdered Eucalyptus Gum.*—Dark reddish brown; in angular fragments with a conchoidal fracture, the thinner pieces light yellow or light reddish brown; upon mounting in water the fragments gradually disintegrate, leaving colorless granular particles and a few cellular fragments. An aqueous solution of Eucalyptus Gum is faintly acid to litmus, and has reddish color, the color being intensified by an aqueous solution of an alkali. A very dilute solution gives a dark green color with ferric chloride T.S., while a more concentrated one yields a dark green precipitate. Almost completely soluble in alcohol without becoming plastic." *N. F.*

"In very dark reddish-brown grains or small masses. Thin fragments transparent and ruby-red, or garnet-red. Inodorous; taste astringent. Tough and adhering to the teeth when chewed. Not less than 80 per cent. soluble in *water.* Almost entirely soluble in *alcohol* (90 per cent.)." *Br.*

Eucalyptus kino contains about 47 per cent. of kino-tannic acid besides small amounts of catechin, pyrocatechin and kinoin, and in some specimens a volatile oil, giving a slightly aromatic odor to the drug, which is especially developed by hydrochloric acid. J. H. Maiden (*A. J. P.,* 1895, 575) states that Australian kino contains *eudesmin* and *aromadendrin.* The former of these when purified exists as a pure mass with a luster resembling spermaceti. It is soluble in hot water, but crystallizes out again on cooling. It is soluble in alcohol, ether, acetic ether, and chloroform, but not in benzene, petroleum spirit, or carbon disulphide. It is dissolved by sulphuric acid with a dark color changing to purple, by nitric acid with a beautiful yellow color. Its formula is given as $C_{26}H_{30}O_8$, and its melting point as 99° C. The second substance was also obtained crystallized from boiling water, and melted at 162° C. No analysis has been made of it.

Botany Bay kino is the inspissated juice of *Eucalyptus calophylla* R. Brown and some other Australian species of Eucalyptus. It occurs in irregular dark red pieces and contains a tannin which will not gelatinize in solution.

Uses.—Red gum does not equal kino in astringency. It is used for *diarrheas of relaxation,* and other affections for which kino has been employed, and is also largely employed as the basis of lozenges and gargles for the relief of relaxed conditions of the pharynx.

Dose, from five to twenty grains (0.3–1.3 Gm.).

Off. Prep.—Trochiscus Kino Eucalypti, *Br.* Trochisci Eucalypti Gummi, *N. F.*

EUCALYPTOL. U. S.

EUCALYPTOL [Cineol]

"A substance [$C_{10}H_{18}O$] obtained from oil of eucalyptus and from other sources." *U. S.*

Cajuputol Eucalyptolum, *Fr. Cod.;* Cinéol, Terpane, Cajeputol, *Fr.;* Terpan, *G.;* Eucaliptol, *Sp.*

In the distillation of eucalyptus leaves, the portion which comes over between 170° C. and 178° C. is set aside as crude eucalyptol. To obtain it pure a redistillation from potassium hydroxide or calcium chloride is necessary. It is very liquid, nearly colorless, with a strong, aromatic, camphoraceous odor, is slightly soluble in water, but very freely soluble in alcohol. Nitric acid produces with it a crystallizable acid; by the action of phosphoric anhydride (*J. P. C.,* 4e sér., xii, 204) it is converted into *eucalyptene,* $C_{10}H_{16}$, a substance allied to cymene, and *eucalyptolen.*

C. Jahns (*A. J. P.,* 1885, p. 237) gave the formula $C_{10}H_{18}O$ to eucalyptol, and showed it to be identical with cajuputol, or, as it is now generally known, *cineol.* Wallach (*Ann. Ch. Ph.,* 248, pp. 278 to 283) showed that the oil from *E. Globulus* contained cineol (eucalyptol) and dextro-pinene, while that from *E. amygdalina* Labill., contained cineol and lævo-phellandrene. (For the nearer study of oil of eucalyptus and for consideration of other eucalyptol bearing oils, see under *Oleum Eucalypti.*)

Eucalyptol forms condensation compounds with a number of phenols in equimolecular proportions. These have been studied and classified by Belluci and Grassi (*Chem. Zentral.,* 1914, 884).

Description and Physical Properties.—"A colorless liquid, having a characteristic aromatic, distinctly camphoraceous odor, and a pungent, spicy taste. Eucalyptol is very slightly soluble in water. It is miscible with alcohol, chloroform, ether, glacial acetic acid, and with fixed or volatile oils.

"Specific gravity: 0.921 to 0.923 at 25° C. It boils between 174° and 177° C. Congealing point: not below 0° C. Place 1 cc. of Eucalyptol in a freezing mixture and gradually add an equal volume of phosphoric acid; a solid, white, crystalline mass of eucalyptol-phosphoric acid forms, and upon the addition of warm water, the Eucalyptol separates.

"Its alcoholic solution (1 in 10) is neutral to moistened litmus paper. Eucalyptol is optically inactive (*difference from oil of eucalyptus and many other volatile oils*). Shake 5 cc. of Eucalyptol with 5 cc. of sodium hydroxide T.S.; the volume of the Eucalyptol is not diminished (*phenols, etc.*). Shake 1 cc. of Eucalyptol with 20 cc. of distilled water, and allow the liquids to separate. To 10 cc. of the acueous layer, separated from the Eucalyptol, add 1 drop of ferric chloride T.S.; no violet color is produced (*phenols*). *U. S.*

Uses.—Eucalyptol has to a considerable extent replaced the oil of eucalyptus especially as a stimulant expectorant in *chronic bronchitis* and *bronchorrhea,* etc. Berliner (*B. K. W.,* 1913, p. 1703) injected hypodermically an oily solution of menthol and eucalyptol in the treatment of *tuberculosis of the lungs* with asserted great benefit. Eucalyptol has been also used to a considerable extent as a vermifuge, especially against the ankylostoma, but has largely been abandoned for remedies more efficient for this purpose. Locally it possesses mildly anesthetic and antiseptic powers and is widely used in the treatment of inflammatory conditions of the nose and throat in strengths of from ½ to 2 per cent. According to the investigations of Martindale its germicidal powers are about equal to those of phenol. Grieg-Smith (*Bot. Abst.*, 1921, vii, p. 189) finds that eucalyptol is germicidal in more dilute solution than phenol, but is decidedly slower in action, so that the phenol coefficient depends upon the length of exposure; at five minutes' exposure eucalyptol and phenol are about of equal potency. Recently it has come into wide-spread use as a solvent for Dichloramine-T. Brownscomb (*Chemist and Druggist,* 1910), however, asserts that eucalyptol is a less powerful antiseptic than the other ingredients of the oil of eucalyptus. For information on the poisonous properties of this principle see *Oleum Eucalypti.*

Dose, five to ten minims (0.3–0.6 cc.), four to six times a day.

Off. Prep.—Liquor Antisepticus, *N. F.;* Liquor Antisepticus Alkalinus, *N. F.;* Liquor Pepsini Antisepticus, *N. F.;* Nebula Aromatica, *N. F.;* Nebula Eucalyptolis, *N. F.;* Nebula Mentholis Composita, *N. F.;* Petroxolinum Eucalyptolis, *N. F.;* Petroxolinum Iodoformi, *N. F.;* Petroxolinum Sulphuratum Compositum, *N. F.;* Pulvis Antisepticus, *N. F.*

EUCALYPTUS. U. S.

EUCALYPTUS Eucalypt.

"Eucalyptus is the dried, scythe-shaped leaf of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*). Eucalyptus contains not more than 3 per cent. of stems, fruits, or other foreign organic matter." *U. S.*

Blue Gum-tree Leaves, Australian Fever-tree Leaves, Eucalyptus Leaves; Eucalyptus, *Fr. Cod.;* Feuilles d'Eucalyptus, *Fr.;* Eucalyptusblätter, *G.;* Eucalitto, *It.;* Eucalipto (Hoja de), *Sp.*

The genus *Eucalyptus* was named by L'Heritier in 1788, from the two Greek words, *εὐ,* well and *καλύπτω*, I cover, in allusion to the operculum formed of the fused petals and calyx lobes, which covers the flower until the stamens have matured and then separates from the calyx-tube by transverse dehiscence. This genus comprises about 300 plants, mostly trees, all natives of Australia, Tasmania and Malayan regions. The leaves are simple and entire on young shoots and seedlings, dorso-ventral, opposite, sessile, with cordate bases, on older parts; usually bifacial, alternate, with twisted petioles and lanceolate to falcate in outline, the leaf parenchyma containing numerous oil-glands. The flowers vary from white through yellow to red and are arranged in corymbs or panicles of umbels. Each has an obconic, bell-shaped or oblong calyx tube adnate to the base of the ovary, the petals and calyx lobes connate, forming a lid which separates from the calyx-tube by transverse dehiscence, numerous stamens and a compound pistil with an undivided style. The fruit is a 3- to 6-celled woody pyxis containing numerous small seeds, many of which are sterile.

Some of the species, according to Kerner, attain a height of 140 to 152 meters and so become close rivals of the giant sequoias of California which have been recorded as the tallest trees known.

Most of the species do not require excessive heat for their perfecting, and some of them are able to resist moderate frosts. Over forty species are being grown successfully in the United States, chiefly in California, where volatile oil has been produced on an experimental scale and leaves collected in commercial amounts. On account of the rapidity of their growth and the hardness and indestructibility of their timber, many of the species are very valuable for economic purposes. A number of the species are cultivated in the southwest as a source of honey. (For methods of cultivation of *Eucalyptus globulus* and other species see *Bulletin No. 35 of the U. S. Bureau of Forestry* and *Univ. of Calif. Agr. Exp. Sta., Bull.* 196).

With a genus of so many species and numerous varieties it was to be expected that there would be considerable confusion in regard to the accurate determination of its species. Tate and Luehman give prominence to the fruit for purposes of classification. Maiden, however, says that all of its characters display a puzzling amount of variation, and concludes that for herbarium work the best characters are afforded by the anthers and fruits; whereas the scientific forester will be largely guided by the nature of the bark and timber. Baker and Smith, in addition to morphological characters, base their deductions on the chemical properties and physical characters of oils, dyes, kinos, etc. (*A Research on the Eucalypts,* Sydney, 1902.) Up to the present no satisfactory natural classification has yet been devised for this large genus. For purposes of identification of herbarium specimens it is necessary to have mature fruits, adult leaves, buds and flowers. By far the most extensive treatise on the genus Eucalyptus is that entitled *"A Critical Revision of the Genus Eucalyptus"* by J. H. Maiden now (1925) appearing in parts. It is stated that the leaves of the *E. rebaudianum,* of Paraguay, are used in that country in place of sugar, which they exceed in sweetening power.

Eucalyptus globulus is a large evergreen tree, attaining a height of 300 or even 350 feet, with a smooth, ash-colored bark. The leaves attain a foot in length, and vary, according to age, from a glaucous white to a bluish-green color. The flowers are large, pinkish-white, axillary, occurring singly, or in clusters. Although its wood is very resinous, hard, and durable, the tree is remarkable for the rapidity of its growth, reaching, under favorable circumstances, fifty feet of height in five or six years. It flourishes best in valleys having a rich, moist soil, and has very largely been naturalized in semi-tropical countries, partly on account of its economic value, but chiefly because of the reputation it enjoys as a means of overcoming malaria. Its sanitary powers appear to be established, numerous notoriously miasmatic stations and districts having been rendered healthful by its growth. It is probable that the destruction of the miasma is due not so much to emanations from the tree as to the fact that it evaporates water so rapidly from its innumerable large leaves as to drain the swamps and marshes in which it is planted. It is possible, however, that the large amount of volatile oil which must escape from it has some effect, and it is even affirmed (*A. J. P.*, 1875, p. 423) that the parasitic phylloxera will not attack grapevines growing near it.

Eucalyptus globulus is cultivated in Spain, Portugal, Italy, France, Algeria, California and other warm countries. The leaves should be collected from older parts of the tree, for such contain the maximum quantity of volatile oil. The drug used in America is collected chiefly from trees grown in southern Europe. It is exported from Spain, France and Belgium to the United States. Small amounts of the drug have been obtained from California but are not at present (1925) commercially available.

Burke and Scalione (*J. I. E. C.*, 1915, 206) made an investigation of oil distilled from *Eucalyptus globulus* in California and found the oil to have the same qualitative composition as the Australian oil but to vary widely in the proportions of the various constituents from the average content of the Australian oil. They found the California oil to be insoluble in 70 per cent. alcohol and to contain 47 per cent. of cineol and 22 per cent. of pinene. *Eudesmol*, *globulol* and aldehydes of butyric, capronic and isovaleric acids were also found.

Description and Physical Properties.—"*Unground Eucalyptus.*—Blades lanceolate, curved, from 8 to 30 cm. in length and from 2 to 7.5 cm. in breadth; apex acute or acuminate; base unequal, obtuse or rounded; petiole twisted, from 5 to 35 mm. in length; margin uneven, revolute; coriaceous; both surfaces varying from pale yellowish-green to grayish-green and more or less glaucous, glaborous, glandular-punctuate and with numerous small, circular brown dots of cork; veins of the first order anastomosing to form a vein nearly parallel with the margin; odor aromatic; taste aromatic, bitter and cooling.

"*Structure.*—The epidermis of both surfaces composed of polygonal cells with rather thickened, straight walls, sunken stomata and strongly thickened cuticle; palisade of 3 to 4 rows beneath each epidermis; loose mesophyll of but a few rows of cells; large oil reservoirs with yellowish or orange-colored contents; collenchyma strands at the edges of the blade and at the ribs; rosette aggregates or mono-clinic prisms of calcium oxalate abundant in the parenchyma; occasional brown corky lenticels deeply depressed into the palisade.

"*Powdered Eucalyptus.*—Light green; containing fragments of epidermis with stomata nearly invisible because of the thickened cuticle; fragments of chlorenchyma with broken oil reservoirs; fragments of brownish cork; long, slightly lignified bast-fibers associated with small dotted tracheæ; calcium oxalate in rosette aggregates or prisms, from 0.015 to 0.025 mm. in diameter." *U. S.*

Hans Kramer (*B. P. G.*, 1907, p. 319) presents an anatomical study of Eucalyptus with the characteristics of the drug in a powdered form.

Eucalyptus owes its medicinal value to a volatile oil of which the fresh leaves afforded 2.75 per cent., the recently dried leaves 6 parts; leaves which had been kept some time yielded a much smaller percentage. (Cloez, *J. P. C.*, 1870; Broughton, *P. J.*, 1873.) In the distillation, the oil for a time comes over freely at from 170° C. to 178° C.; subsequently another portion of oil distils at 188° C. to 190° C., and finally a very minute portion does not volatilize until the temperature reaches 200° C. The bulk of the oil yielded is the portion first distilled; to this Cloez gave the name of *eucalyptol.* (See previous article.)

The oils distilled from the leaves and from the twigs or wood of the various species of this very large genus, are so dissimilar in composition and properties in many cases that the generic term "eucalyptus oil" is without definite meaning unless the species is known. Gildemeister and Hoffmann (*Aetherische Oele*, 1899, p. 690) divide the eucalyptus oils into 5 groups according to their constituents, viz.: Group 1, Cineol- (or Eucalyptol-) containing oils, of which group *Eucalyptus Globulus* is the most important; Group 2, Citronellal-containing oils, of which group *Eucalyptus maculata* is the most important; Group 3, Citral-containing oils, of which *E. staigeriana* F. von Muell. is the typical example; Group 4, Peppermint smelling oils, of which *Eucalyptus piperita* is an example; and Group 5, Less known oils of varying odor. See also *Oleum Eucalypti.*

Schimmel & Co. (*Semi-Annual Report,* April, 1897) gave a list of some fifteen varieties of eucalyptus oils from the different Eucalyptus species. In their report for October, 1904, they give the sources and state the properties and components of 109 different eucalyptus oils obtained by them from Baker and Smith, Curators of the Technological Museum of Sydney, N. S. W.

The *E. purpureum* L. (*Joe-Pye Weed*) and the *E. verbenæfolium* Michx. (*wild horehound*) have been used as folk remedies for the same purposes as the official drug. *E. incarnatum* Walt. and *E. aromaticum* L. are said to contain an aromatic principle similar to, if not identical with, coumarin. (See *P. J., Oct.*, 1874, 303.) The *E. ageratoides* L.f., commonly known as *white* *snake-root,* has been popularly supposed to give rise to a disease of cattle known as the "trembles," but Crawford (*Bureau of Plant Industry,* Bull. 121, 1908, U. S. Dept. of Agriculture) was unable to find any evidence of toxicity in the plant. *E. Rebaudianum* contains a principle, *rebaudin,* which is stated to have 180 times the sweetening power of sugar and has been suggested as a substitute for saccharine.

For account of other species of Eupatorium see *U. S. D.,* 20th ed., p. 1380.

Uses.—Whatever medicinal virtue eucalyptus possesses—beyond a slight astringency—is due to its volatile oil. Preparations of the crude drug are rarely used in this country. The leaves are occasionally rolled into cigarettes to be smoked for the relief of *bronchitis* or *asthma.* Certain French authors have reported a beneficial effect from infusion of eucalyptus in diabetes but John (*J. Metabol. Research,* 1922, i, 489) made a careful test in twenty patients with entirely negative results. For therapeutic properties see *Oleum Eucalypti.*

Dose, of eucalyptus, ten to thirty grains (0.65–2.0 Gm.); of the oil, five to ten minims (0.3–0.6 cc.).

Off. Prep.—Fluidextractum Eucalypti, *U. S.*

EUGENOL. U. S.

EUGENOL

"A phenol [$C_6H_3.C_3H_5.OCH_3.OH$ 1:3:4] obtained from clove and other sources." *U. S.*

Ollylguaiacol, Allylmethylpyrocatechol; Eugenol, *Fr.;* Aleum Caryophyllorum, ***P.*** *G.;* Eugenol, *G.*

Eugenol is extracted on a large scale from oil of cloves and utilized as the starting point in the manufacture of artificial vanillin. (See *Vanillinum.*) It is also found in pimenta, cinnamon leaves, sassafras, canella, bay and other plants. It has been shown to be the methyl ether of allyl-dioxybenzene. One of its most important reactions is its conversion into vanillin. It yields a characteristic benzoyl derivative which melts at 69° to 70° C. Methyl eugenol is also known. For the manufacture of vanillin it is first converted into an isomeric compound which has a different side chain arrangement. This *iso-eugenol* is found naturally in certain volatile oils, as nutmeg and ylang-ylang.

Description and Physical Properties.—"A colorless or pale yellow, thin liquid, having a strongly aromatic odor of clove, and a pungent, spicy taste. Exposure to air causes it to become darker and thicker. Eugenol is slightly soluble in water, but is miscible with alcohol, chloroform, ether, and with fixed oils. It is soluble in twice its volume of 70 per cent. alcohol.

Specific gravity: 1.0 4 to 1.070 at 25° C. Eugenol boils between 250° and 255° C. It is optically inactive and strongly refractive. A mixture of 1 cc. of Eugenol and 20 cc. of hot distilled water is only very slightly acid to litmus paper. Dissolve 1 cc. of Eugenol in 12 cc. of sodium hydroxide T.S., and add 18 cc. of distilled water; a clear solution results which becomes turbid when exposed to air (*hydrocarbons*). Shake 1 cc. of Eugenol with 20 cc. of distilled water, filter, and add 1 drop of ferric chloride T.S. to 5 cc. of the clear filtrate; a transient grayish-green color, but not a blue or violet color, is produced (*phenol*).

Preserve in well-stoppered containers, in a cool place, protected from light." *U. S.*

Uses.—The medicinal properties of eugenol are practically the same as those of Oil of Cloves. Our own experiments, as well as those of Martindale, indicate, however, that it is slightly less active as an antiseptic than natural oil. It is much used by dentists for disinfecting root-canals.

Dose, two to five minims (0.12–0.3 cc.).

Off. Prep.—Mistura Olea Balsamica, *N. F.*

EUONYMUS. N. F. (Br.)

EUONYMUS Euonym. [Wahoo Bark]

"Euonymus is the dried bark of the root of *Evonymus atropurpureus* Jacquin (Fam. *Celastraceæ*). Euonymus contains not more than 5 per cent. of adhering wood or more than 2 per cent. of other foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

"The dried root bark of Euonymus atropurpureus, *Jacq.*" *Br.*

Euonymi Cortex, *Br.;* Cortex Euonymi; American Indian Arrow-wood; Ecorce d'Evonymus, *Fr. Cod.;* Spindlebaum, Pfaffenhütchen, Spillbaumrinde, *G.*

Euonymus (more properly *Evonymus*) *atropurpureus,* named variously *wahoo, spindle-tree,* and *burning-bush,* is a tall, erect shrub or rarely (frequently, west of the Mississippi) a slender tree with quadrangular branchlets, and opposite, petiolate, oval-oblong, pointed, serrulate, membranous leaves. The flowers, which stand in loose cymes on axillary peduncles, are small and dark purple, with sepals and petals commonly in fours. The fruit is a deeply 3- to 4-lobed crimson-purple capsule, each lobe dehiscing to expose a seed which is covered by a succulent crimson aril. The plant is native to eastern North America, west to Montana, Arkansas and Indian territory.

The plants belonging to the *Euonymus* genus are shrubs or small trees, presenting in the autumn a striking appearance from the rich red color of their fruit, which has obtained for them the name of *burning-bush. E. americanus* L. and *E. europæus* L. have been cultivated in gardens as ornamental plants. Several species have been used in medicine. Their properties are probably similar, if not identical. An oil expressed from the seeds of *E. europæus* was formerly used in Europe for the destruction of vermin in the hair, and sometimes also as an application to old sores. The seeds of a number of this and other species are purgative and emetic and of some the leaves are poisonous to sheep and other animals feeding on them. It is probable that much of the wahoo of our drug stores has been obtained from *E. americanus,* which is distinguished from *E. atropurpureus* by its rough, warty, depressed capsules, and almost sessile, thicker leaves.

Description and Physical Properties.—"*Unground Euonymus.*—Usually in transversely curved pieces, occasionally in single quills from 2 to 7 cm. long; bark from 1 to 4 mm. thick; very light in weight; outer surface grayish or light brown, somewhat wrinkled, with soft scaly cork and transverse lenticels, the latter occasionally forming fissures; inner surface grayish white, longitudinally striate and somewhat porous; fracture short with projecting, silky, elastic fibers of a caoutchouc-like substance. Odor distinct; taste bitter and acrid.

"*Structure.*—Cork cells with thin, nearly colorless, lignified walls, the outer layers somewhat collapsed, a zone of isodiametric cortical parenchyma; sieve separated by bast parenchyma and wavy secondary medullary rays, the latter, one cell in width; the medullary ray cells and parenchyma contain starch or rosettes of calcium oxalate; elongated secretory cells with a brownish or yellowish amorphous content distributed throughout the middle and inner bark.

"*Powdered Euonymus.* — Light brown; numerous starch grains, nearly spherical, from 0.003 to 0.012 mm. in diameter; fragments of cork; elongated fragments of secretion cells; numerous fragments of starch-bearing parenchyma; calcium oxalate in rosettes from 0.015 to 0.060 mm. in diameter, the amount in different specimens showing some variation. Prisms of calcium oxalate are wanting." *N. F.*

"In quilled or curved pieces, from two to four millimetres thick. Outer layer a soft, friable, greyish cork, marked with dark patches. Inner surface pale tawny-white and smooth. Fracture short, the fractured surface yellowish in color. Transverse section free from sclerenchymatous cells and fibres, and exhibiting, in the secondary bast, laticiferous cells filled with a granular, elastic substance. Faint but characteristic odor; taste somewhat mucilaginous, afterwards bitter and slightly acrid." *Br.*

The chief adulterant of Euonymus within recent years has been the bark of the *Wafer Ash, Ptelea trifoliata* L. (Fam. *Rutaceæ*). The latter may readily be distinguished from Euonymus, upon fracture, by its absence of caoutchouc threads extending between the broken surfaces, the latter appearing waxy and pale yellow. It can be identified microscopically by the layer of stone cells beneath the cork, the presence of prismatic and rosette crystals of calcium oxalate, the former in the outer parenchyma of the cortex, the numerous oleoresin cells scattered throughout the parenchyma and the absence of secretory cells containing a caoutchouc-like material. For detailed anatomical distinctions between these barks see paper by H. W. Youngken in *A. J. P.,* 1918, p. 160.

The bark frequently has had as much as 25 per cent. of adhering wood. The amount of the latter with other foreign matter should not exceed 3 per cent. Holm (*Merck's Rep.,* 1909, p. 169) illustrates the structural characteristics of *E. atropurpureus* and *E. americanus.* Holmes (*P. J.,* 1905) describes the bark of *Alstonia scholaris* R. Br., which has been used as an adulterant of Euonymus. The name of Wahoo (pronounced *Wawhoo*) was given to it by the Indians who employed a decoction of the inner bark of the *E. atropurpureus* in uterine troubles. The same name has also been applied to *Ulmus alata* Michx. of the southern States, and has thus led to mistakes.

The term *euonymin* has been applied (1) to the resinous matter which is precipitated by adding water to an alcoholic tincture of the drug; (2) to a crystallizable bitter principle isolated by Wenzell in 1862 and (3) to a glucoside found by Meyer and Romin (*Ph. Central.,* 1885), although the term *euonymo-toxin* has been suggested for this glucoside. This glucoside is stated to exercise a digitalis-like effect on the heart. Frank V. Cassaday (*A. J. P.,* 1889, p. 284) found 1.30 per cent. of volatile oil and resin, 1.48 per cent. of *euonic acid* and resin, 2.10 per cent. of euonymin and resin, together with the usual plant constituents. Kubel has discovered in the fresh inner bark of *E. europæus* a saccharine, crystallizable substance, closely resembling mannite, but differing in its crystalline form and in its melting point. He calls it *euonymite.* (*J. P. C.,* Dec., 1862, 523.)

H. Rogerson (*P. J.,* 1912, p. 687) has made a complete chemical examination of this bark with the result that the following definite constituents are reported present: dulcitol; *furan—β—carboxylic acid,* $C_5H_4O_3$; *euonymol,* $C_{21}H_{30}O_4$ (a new crystalline alcohol, having a melting point of 248° C.); a sugar which yielded *d-phenyl glucozazone; euonosteryl,* $C_{31}H_{51}O.OH$; *homoeuonosteryl,* $C_{40}H_{69}O.OH$; *atropurol,* $C_{27}H_{44}(OH)_2$; *citrullol,* $C_{22}H_{36}O_2(OH)_2$; and a mixture of palmitic, cerotic, oleic and linoleic acids. No glucoside was found.

Uses.—This bark was introduced many years ago as a remedy for *dropsy,* but has been used chiefly for its cathartic action. By the eclectics it was supposed to exert an especial effect on the liver and was used in cases of *chronic constipation, dyspepsia,* etc. Its use, however, is not to be recommended because of the possibility of an undesirable effect upon the circulation.

Dose, of euonymus, five to fifteen grains (0.32–1.0 Gm.).

"*Caution.*—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid possible toxic or cumulative action of the drug the physician should determine in each case the tolerance of the patient and regulate the dosage accordingly." *N. F.*

Off. Prep.—Extractum Euonymi, *Br., N. F.;* Fluidextractum Euonymi, *N. F.*

EUPATORIUM. N. F.

EUPATORIUM Eupator. [Thoroughwort, Boneset]

"Eupatorium consists of the dried leaves and flowering tops of *Eupatorium perfoliatum* Linné (Fam. *Compositæ*). Eupatorium contains not more than 10 per cent. of its stems and not more than 2 per cent. of foreign organic matter." *N. F.*

Boneset; Thoroughwort; Herba Eupatorii Perfoliati, Indian Sage; Thorough-stem; Cross-wort; Thorough-wax; Sweating Plant; Herbe d'Eupatoire perfoliée, Herbe à fièvre, Herbe parfaite, *Fr.;* Durchwachsener Wasserhanf or Wasserdost, *G.*

This is an indigenous perennial plant, with numerous, herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. The leaves serve to distinguish the species at the first glance. They are connate-perfoliate and decussate at regular distances upon the stem. They are narrow in proportion to their length, broadest at the base where the two opposite, sessile leaves have coalesced, gradually tapering to a point, serrate, much wrinkled, paler on the under than on the upper surface, and beset with whitish hairs, which give them a grayish-green color. The uppermost pairs are sessile, not joined at the base. The flowers are all tubular and white, being arranged in corymbs of numerous heads, with hairy peduncles. The involucre, which is cylindrical and composed of imbricated, lanceolate, hairy bracts, encloses from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five, black, and united into a tube, through which the bifid filiform style projects. This species of *Eupatorium* inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the end of October. The leaves and flowering tops are collected from wild plants during late summer and dried in the shade. The commercial supplies are obtained chiefly from the central and southern United States. It has a faint odor, and a strongly bitter, somewhat peculiar taste.

Description and Physical Properties.—"*Unground Eupatorium.*—Usually more or less broken; leaves opposite, the pair united at the base, from 8 to 20 cm. long and from 1.5 to 5 cm. in width, tapering regularly from near the base to an acute apex, crenate-serrate, rugosely veined, rough and bright green above, yellowish gray-green, tomentose and resinous-dotted beneath; flower-heads small, numerous, corymbed, with a campanulate involucre of lance-linear, imbricated scales and with from 10 to 15 tubular yellowish white florets having a bristly pappus in a single row. Odor faintly aromatic; taste strongly bitter.

"*Powdered Eupatorium.*—Dark green; multicellular, non-glandular hairs with thin finely striate walls and end cells pointed or somewhat rounded; glandular hairs, short-stalked with 2-celled heads, the latter from 0.045 to 0.080 mm. in diameter or with a 6- to 8-celled stalk, the cells arranged in a double row and a 4- to 12-celled head; ellipsoidal pollen grains up to 0.025 mm. in diameter, with numerous spiny centrifugal projections; hairs of the pappus, in the form of a multicellular axis with numerous, short, unicellular, alternate branches; tracheæ spiral, annular or with bordered pores; numerous fragments of leaf epidermis showing elliptical stomata from 0.018 to 0.036 mm. in length; many fragments of achene pericarp composed of cells with thick characteristic brownish walls; fragments of stem tissue showing epidermal cells, parenchyma associated with non-lignified, thin-walled porous fibers, tracheæ, and pith parenchyma; numerous fragments of corolla tissue." *N. F.*

George Latin (*A. J. P.,* Aug., 1880) found a glucoside, *eupatorin,* and a crystallizable body of the nature of wax. Shamel (*Am. Chem. J.,* 1892, p. 224) published an analysis of the nitrate of the crystalline principle giving the formula $C_{20}H_{25}O_{36}HNO_3$.

Uses.—In large doses eupatorium is emetic and aperient. It has long been a popular household remedy in a variety of disorders. It probably, however, possesses no therapeutic virtues which are not explicable on the ground of its nauseating properties. Because of this effect the warm infusion tends to increase perspiration and it may be useful as a diaphoretic in the formative stages of colds, muscular rheumatism and similar disorders. Probably through the same action it has been applied in various types of *bronchitis,* and by some is believed to have established virtues when there is a tendency towards asthma.

Dose, thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Eupatorii, *N. F.*

EUPHORBIA. N. F.

EUPHORBIA Euphorb. [Euphorbia Pilulifera, Pill Bearing Spurge]

"Euphorbia is the dried herb of *Euphorbia hirta* Linné (Fam. *Euphorbiaceæ*). Euphorbia contains not more than 5 per cent. of foreign organic matter and yields not more than 3 per cent. of acid-insoluble ash." *N. F.*

Pill-bearing Spurge; Snakeweed; Queensland Asthma Weed; Cat's-hair.

This plant is a prostrate or ascending branched annual indigenous to India, but naturalized in other tropical countries. It is characterized by its slender, cylindrical, hairy stems; the leaves are opposite, oblong-lanceolate, shortly petiolate, denticulate or serrulate, hairy and unequal at the base, they vary from 2 to 4 cm. in length and are often blotched with red. Minute linear stipules are present. The flower-heads are small, numerous, crowded in head-like cymes, globular, and are borne on a short stalk in one axil, only, of each pair of opposite leaves. The involucre is small, entire, and without petal-like appendages. The fruits are small, yellow, 3-celled capsules, each component carpel of which is keeled. The seeds are minute, triangular-ovoid and of a pale brown color. It is to be distinguished from E. *parviflora* (L.), which is sometimes substituted for it, by the head-like cymes of the latter having but few flowers, by the glands of the involucre being furnished with a white, obovate-orbicular appendage, and by the seeds being minutely papillose.

The commercial supplies come chiefly from India. For description of other species see *Euphorbia,* Part II.

Description and Physical Properties.—"*Unground Euphorbia.*—Roots usually present, small, branched, and reddish; stems slender, cylindrical, obliquely erect, dichotomously branched from near the base, branches recurved at apices; branches and stem only sparsely leafed at base, pale greenish brown, rough or hairy, rather densely on the upper parts but sparsely on the lower; leaves opposite, obliquely oblong, acute, serrulate, rusty pale green, pubescent especially on the prominent veins on the lower surface, becoming brittle on drying and usually much broken in the drug; flowers small, numerous, in short peduncled axillary clusters; fruits about 2 mm. in diameter, three-celled capsules; seeds about 0.9 mm. in diameter, triangular-ovoid, pale brown. Odor aromatic and characteristic, taste faintly bitter, aromatic and acrid.

"*Powdered Euphorbia.*—Light yellowish; numerous fragments of lignified tissue composed of wood fibers, wood parenchyma, medullary ray and pith parenchyma, associated with tracheids and tracheæ, the latter from 0.020 to 0.060 mm. in diameter and with bordered pores, spiral or scalariform markings; fragments composed of cork cells containing a reddish brown amorphous content and having walls which are sometimes lignified; numerous spherical to ovoid starch grains, simple to 3-compound, the individual grains from 0.005 to 0.025 mm. in diameter; numerous, thick-walled, lignified fibers from 0.020 to 0.070 mm. in diameter, either isolated or associated with thick-walled, starch containing parenchyma, the latter and latex tubes, the latter with a grayish, amorphous content, few fragments of epidermis from leaf or upper part of stem showing multicellular, yellowish, non-glandular hairs, up to about 0.090 mm. in diameter at the base and up to 0.850 mm. in length, and colorless, curved multicellular, non-glandular hairs up to 0.040 mm. in diameter at the base and up to 0.400 mm. in length." *N. F.*

Levison found in it (*A. J. P.,* 1885, 147) several glucoside resins, wax, and volatile matter. Dr. F. B. Power (*C. D.,* 1913, 544) examined *E. pilulifera* from the Fiji Islands and found a monohydric alcohol, *euphosterol,* among other constituents, none of which seem to possess value therapeutically.

Uses.—A physiological study of *Euphorbia pilulifera* led A. Marsset (*T. G.,* 1885) to the conclusion that the active principle acts directly upon the heart and respiration; that it is not an irritant to the skin, but in large dose it is to the gastric mucous membrane. It has been used by Dujardin-Beaumetz and a number of other clinicians with asserted excellent results in the treatment of *asthma* and *bronchitis.*

Dose of the fluidextract, from a half to one fluidrachm (1.8–3.75 cc.) three or four times a day.

Off. Prep.—Fluidextractum Euphorbiæ Piluliferæ, *N. F.;* Elixir Euphorbiæ Compositum, *N. F.*

EXTRACTA. U. S.

EXTRACTS

"Extracts are either pasty or semi-solid masses, or dry, solid or powdered products, prepared by exhausting drugs with appropriate solvents, carefully evaporating the solutions so obtained to the prescribed consistence and adjusting the products to the fixed standards. An extract is intended to preserve the useful constituents of the drug in a concentrated, relatively uniform, permanent condition and in a form suitable for medication." *U. S.*

Extraits, *Fr.;* Extrakte, *G.;* Estratti, *It.;* Extractos, *Sp.*

Extracts, as the term is employed in the Pharmacopœias, are solid preparations, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing a dried drug to the action of a solvent, or by expressing the juice from a fresh plant. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta,* the latter *Succi Spissati,* but the distinction has been generally abandoned.

The composition of extracts varies with the composition of the plant, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant with as little of the inert matter as possible, though sometimes it may be desirable to separate two active ingredients from each other when their effects upon the system are materially different; this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, coloring matter, salts, and the peculiar principles of plants, to which, when an alcoholic solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil, gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in this commentary. There is one, however, which from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive,* or, as it is sometimes called, *extractive matter.*

It has long been observed that in most plant tissues there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes characteristic changes during the process of evaporation, imparting to the liquid even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep brown color, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive,* derived from its frequent presence in extracts. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will ultimately be separated from the liquid, while the other ingredients may remain. The name of oxidized extractive which has been given to it is incorrect, and Berzelius proposed to substitute for it that of *apothem,* synonymous with deposit. According to Berzelius, apothem is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, probably on account of its colloidal absorptive properties, and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way also, even when the extractive of a plant is itself medicinally inert, its conversion into apothem may be injurious by causing a precipitation of a portion of the active principle, and in practical pharmaceutical operations this change should always, if possible, be avoided.

We shall treat of the subject under the several heads of (1) the extraction of the soluble principles from the plant; (2) the method of conducting the evaporation; (3) the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract: (1) by expression alone; (2) by the agency of a solvent, with or without expression.

1. By Expression.—This method is applicable to fresh vegetable tissues when they are very succulent and when other conditions are favorable. It is not recognized by the U. S. but there are four preparations in the Br. in which expression of juice is employed. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Battley, of London, recommended that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Brande states that light pressure only should be employed, as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. The juice thus obtained is opaque, and usually green, in consequence of the presence of chlorophyll, and of a portion of the undissolved vegetable tissues in minute division. By heating the juice to about 71.1° C. the albumen contained in it coagulates, and, involving the chlorophyll and vegetable fiber, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colorless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle, in which case it should be subsequently incorporated with the juice, when the latter is reduced by evaporation to the consistence of syrup. Chloroform or ether added to the expressed juices of plants enables them to be kept long without injurious change. Lepage, of Gisors, France, has kept the juice of belladonna preserved with ether more than ten years, and found it, at the end of that time, to yield an extract identical in physical, chemical, and physiological properties with that obtained from the fresh juice.

2. By Solution.—"The solvent or menstruum to be employed in the preparation of an extract is dependent upon the physical characteristics of the drug and the nature of its constituents. The solvents commonly adopted are water or alcohol, or mixtures of these, in the proportions directed in the formulas. For the extraction of a few drugs, the addition of an acid or an alkali to the solvent is required. When alcohol is used as a solvent, it may be recovered by distillation. When a drug contains an oily constituent that is extracted by the menstruum, it becomes necessary to adopt in the process of manufacture some method for the separation of this oil so that a permanent product of the proper consistence, dryness, or pulverulent form may be obtained." *U. S.*

The active principles of dried vegetable substances can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action if necessary by a higher degree of heat than the latter. Tap water is often unfit for the purpose, in consequence of the quantity of its saline matter, which in some instances may exert an unfavorable influence on the active principle, and must always be left in the extract. Distilled water is preferred. Alcohol is employed when the principles to be extracted are insoluble or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The aqueous solution requires to be quickly evaporated, as this fluid rather promotes than counteracts chemical changes, while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable, and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively than of both united. Extracts obtained by the agency of water are called *aqueous extracts;* those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts.* Sometimes the term *hydro-alcoholic* is applied to extracts obtained by the joint agency of alcohol and water. The methods of extraction are by infusion, decoction, maceration or percolation.

Chloroform is frequently used to saturate the water used in making aqueous extracts to prevent fermentation during percolation.

It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. Experiments have shown that strong acetic acid (60 per cent.) is a powerful solvent for the active properties of various drugs, particularly those which contain volatile oils, and in many cases a 10 per cent. acetic acid is an excellent menstruum for making extracts; for these the name *acetract* has been proposed. (*Proc. A. Ph. A.,* 1897, 416.) E. R. Squibb has used acetic acid largely for extracts. (*West. Drug.,* 1897, 123.)

Ether also is now used to a considerable extent in the preparation of oleoresins which are a class of extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the extraction of drugs the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation, and the ether is then allowed to escape by spontaneous evaporation, or distilled off at a very moderate heat. The oleoresinous extracts thus obtained are usually of a thick fluid or semifluid consistence. Several of them now rank among the official preparations, in the U. S. P., under *Oleoresinæ.* Acetone is another solvent used much for the same purpose as ether.

"**Powders—Fineness.**—The fineness of vegetable drugs is expressed in this Pharmacopœia by the following terms: (1) *coarse powder* (No. 20), (2) *moderately coarse powder* (No. 40), (3) *fine powder* (No. 60), (4) *very fine powder* (No. 80). A powder to conform to any one of these specified terms must meet the requirements given below. In the preparation of ground or powdered drugs, no portion of the drug shall be rejected during milling or sifting unless specifically permitted under the official description of the drug. It is permissible, however, to withhold *final tailings* not exceeding 5 per cent. of the drug being powdered, which may be added in no greater percentage to other lots of the same drug in subsequent millings.

"STANDARDS FOR UNIFORMITY OF FINENESS.—A *coarse powder* (No. 20) is one in which all of the particles will pass through a No. 20 standard mesh sieve and not more than 40 per cent. through a No. 60 standard mesh sieve. A *moderately coarse powder* (No. 40) is one in which all of the particles will pass through a No. 40 standard mesh sieve and not more than 40 per cent. through a No. 80 standard mesh sieve. A *fine powder* (No. 60) is one in which all of the particles will pass through a No. 60 standard mesh sieve and not more than 40 per cent. through a No. 100 standard mesh sieve. A *very fine powder* (No. 80) is one in which all of the particles will pass through a No. 80 standard mesh sieve."

The "standard *sieves*" referred to in the official description is intended to mean those that meet the standards of the U. S. Department of Commerce (*Circular* LC, 74, April 15, 1924). This circular describes in detail the size of the opening, diameter of the wire and shape of sieve necessary to conform to Federal regulations; manufacturers may have their sieves certified by the Bureau of Standards by payment of a small fee. The meaning of the numbers adopted can be most readily explained by the following quotation from this Circular:

"Because of the wide range of openings in sieves now manufactured which is possible with a given number of meshes per unit length by the use of wires of different diameters, and the consequent confusion and uncertainty which arises in designating sieves by the number of meshes per unit length, it is recommended that all reference to mesh be avoided in the designation of the sieves, but that for convenience each sieve be given an abstract number which will indicate the approximate position of the sieve in the series. The proper designation of a sieve is the size of the opening, supplemented by the wire diameter, but it is well recognized that few users of sieves will be able to carry the sizes of the various openings in mind without reference to a printed table. All that the users of sieves desire to know in general is that the sieves are 'standard,' that is, that they conform to established specifications, and therefore the only designation required is a simple one which will suggest the degree of fineness or coarseness of the material passing or retained upon any given sieve. Such a designation is an abstract number which is approximately the number of meshes per linear inch. The advantage of such a designation is readily apparent. Thus the sieve, which has a 0.105 mm. opening, is given the number 140, which may be regarded simply as a fixed arbitrary number indicating that the sieve has approximately 140 meshes per inch. The fact that a sieve of nominal opening and wire diameter has actually 141.9 meshes per inch or 55.9 meshes per centimeter is of no importance; the number 140 merely indicates to those who are familiar with the old sieves what order of separation this sieve would give in testing any graded material. It is urgently recommended that all users of sieves in the future designate these standard sieves by these arbitrary numbers approximately the mesh per inch, and that the manufacturers mark and list the sieves in this manner, together with the size of the openings and the wire diameters in both millimeters and inches." *Circular,* U. S. Bureau of Standards.

"METHOD FOR DETERMINING UNIFORMITY OF FINENESS.—For determining uniformity of degree of fineness of a powdered vegetable drug, the following process shall be used, employing standard testing sieves which meet the requirements of the Bureau of Standards, U. S. Department of Commerce. For *coarse* and *moderately coarse powders,* place from 25 to 100 Gm. of the powder to be tested upon the proper standard testing sieve with a tightly fitting receiving pan and cover. Shake the sieve in a rotary horizontal direction and vertically by tapping on a hard surface for not less than twenty minutes or until no appreciable number of particles pass through the sieve. Weigh accurately the amount remaining on the sieve and in the receiving pan and calculate to per cent. In the case of *fine* or *very fine powders,* proceed as for *coarse* or for *moderately coarse powders,* but shake the sieve for at least thirty minutes or until no appreciable number of particles pass through the sieve. In the case of oily or other powders which tend to clog the openings, the screen should be carefully brushed at intervals during the test. In the case of powders which tend to form lumps, such lumps should be carefully disintegrated during the sifting test. In all cases care must be taken not to increase the fineness of the powder during the process of sieve testing.

"Mechanical testing machines which impart a rotating and tapping effect to the testing sieves may be employed for making the tests. In all cases care must be taken to see that the separation is complete before the weighings are made.

"**Percolation and Maceration.**—*Percolation,* as directed in this Pharmacopœia, consists in subjecting a comminuted substance or a mixture of substances, contained in a vessel called a percolator, to the solvent action of successive portions of a liquid termed the menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall extract the soluble constituents, and pass from the percolator free from insoluble matter. When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator will be nearly saturated with the soluble constituents of the substance treated; and, if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself. In preparations which direct the process of percolation, wherever the expression 'until the drug is exhausted' or a similar phrase occurs, it is to be understood that the term 'exhausted' means that point at which the valuable constituents have been as completely extracted as is practicable, and this must be determined by the judgment and experience of the operator.

"*Percolators.*—The following statement with regard to percolators and the process of percolation is given in order to illustrate a method of percolation. It is not intended to be compulsory and it is permissible for manufacturers and others to modify the process to suit their needs. The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become wider toward the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby (when it is desired to interrupt the percolation) the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band or wire loop holding the tube in position. The shape of the percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a weak alcoholic or an aqueous menstruum is employed, a *conical* percolator is preferable. A *cylindrical* or only slightly tapering percolator may be used for drugs which are not likely to swell, particularly if difficult to exhaust, also when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug extracted. When properly packed, the drug should not occupy more than two-thirds of the height of the percolator. The percolator is best constructed of glass, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum. Metallic percolators are required for hot percolation. The percolator is prepared for percolation by gently pressing a small tuft of purified cotton into the neck, and this may then be moistened by pouring a few drops of menstruum upon the cotton, to facilitate the passage of the first portion of percolate, which is often very dense.

"*The Process.*—The substance to be percolated, of the fineness directed in the formula, and thoroughly air-dried before it is weighed, is put into a suitable dish, sufficient menstruum is poured on, and the powder stirred until it is uniformly moistened. The moist powder is then passed through a sieve. Coarse powders usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed. After maceration, the moist powder is removed from the percolator, and then returned in suitable portions, pressing each portion, with the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum. Strongly alcoholic menstrua, as a rule, permit firmer packing of the powder than weaker menstrua. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disc of filter paper, held in place by a layer of washed sand or a glass stopper or percolator weight, and a sufficient quantity of the menstruum is poured on through a funnel reaching nearly to the surface of the paper. If these conditions are accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time for maceration specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle, previously marked for the quantity of liquid to be received, if the percolate is to be measured, or tared, if the percolate is to be weighed. By raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable. A layer of menstruum must constantly be maintained above the powder, to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

"When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as described, and the liquid poured on until all has passed from the surface, when immediately a sufficient quantity of the directed menstruum should be poured on to displace the retained liquid and obtain the prescribed quantity.

"*Repercolation or Fractional Percolation.*—Authority is given to employ, where it may be applicable, the process of repercolation, without change of the initial menstruum or the process of fractional percolation, described in Type Process C for fluidextracts.

"*Rate of Flow.*—The success of the process of percolation largely depends upon the regulation of the flow of the percolate; if this is too rapid, incomplete exhaustion will result, but if too slow, valuable time is wasted and considerable loss of menstruum occurs from evaporation. For fluidextracts using 1000 Gm. of powder, the rate of flow should not exceed ten drops a minute; for official quantities of tinctures and preparations of about the same strength, twenty drops a minute, and the word "slowly" throughout the text is understood to mean a rate of flow corresponding to this. The proper rate of flow should vary with the quantity and character of the drug employed and the density of the menstruum.

"*Maceration.*—Percolation is not suitable for exhausting some drugs, and for such the process of maceration is employed. The tinctures of asafetida, sweet orange, and tolu are illustrations. Maceration should be conducted preferably at a temperature of from 15° to 20° C. Specific directions will be found in the monographs." *U. S.*

For an account of E. R. Squibb's process of repercolation, see *Fluidextracta.*

Large scale production enables the pharmaceutical manufacturer to employ vacuum stills for recovering the solvents and enabling concentration to be effected at temperatures which are not injurious to the principles involved.

2. *Mode of Conducting the Evaporation.*

"In the preparation of extracts, the concentration of the liquid extractions is to be completed without delay, and undue exposure to heat must be avoided. The limit of temperature for the evaporation, as stated in the formulas, should not be exceeded. In the manufacture of extracts on a large scale, apparatus for distilling and evaporating under reduced pressure should be used. It is also important that the residue be frequently stirred in order to hasten the evaporation and to obtain a uniformly smooth product. In the preparation of powdered extracts, it is necessary to use solvents that will extract the active principles of the drug and only a minimum amount of inert substance. The drying of the soft extract can be greatly facilitated by spreading it upon plates of glass or tinned metal and exposing it to currents of warm dry air. Powdered extracts must be thoroughly dried, powdered, intimately mixed with the diluent, and carefully preserved as directed below." *U. S.*

In evaporating the solutions, attention should always be paid to the fact that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapor. The operator should, therefore, observe two rules: (1) to conduct the evaporation at as low a temperature as is consistent with other objects; (2) to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. The injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case, and therefore a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. First, however, it is proper to observe that decoctions generally let fall, upon cooling, a portion of insoluble matter, and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble substance formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a rule, is to allow it to remain.

The method of evaporation formerly resorted to in the case of aqueous solutions is rapid boiling over a fire. This method has been entirely superseded by the use of steam in connection with reduced pressure.

The use of the vacuum kettle or evaporator has become very general in this country, as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, may be considerably less than 100° C.

A former plan of evaporation, though slow, was to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 37.8° C., or a little higher, taking care that the air have free access in order to facilitate the evaporation.

In the concentration of alcoholic solutions, distillation should always be performed, as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. When the decoction or infusion and the tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom and not to the sides of the vessel.

"Alkaloidal standards have been adopted for those extracts that can be reliably assayed. Assay methods are directed for the determination of their strengths and to provide for their standardization. When necessary, an inert diluent is directed to reduce the product to the standard. In the official formulas, glucose is directed in most instances as the diluent for the pilular extracts, and dried starch for the powdered extracts. It is permissible, however, for the manufacturer to use as inert diluents, for the former, a sub-standard extract of the same drug; for the latter, sucrose, lactose, powdered glycyrrhiza, magnesium carbonate, or the finely powdered, dried drug or marc from which the respective extract was made. Before admixture the diluent may be colored by the addition of chlorophyll, caramel or other harmless coloring to simulate the color of the extracts. For the convenience of the prescriber, the standards of strength for the extracts have been adjusted wherever possible, so that each bears a definite relation to that of the respective drug of average strength. A statement of the standard adopted accompanies each formula." *U. S.*

C. H. LaWall has prepared a valuable table giving the yield of extract by various drugs. (*Proc. A. Ph. A.*, 1897, 414.) For methods of assay, see various official processes.

"The pasty or semi-solid extracts are designated '*pilular extracts*' because they are extensively used in pill masses. They are also used in ointments, and to facilitate their use in these preparations, the degree of concentration is directed to be that of a 'pilular consistence.' In these, an excess of moisture is to be avoided and the proper pliability and consistence may be maintained by the addition of a small amount of glycerin. Pilular extracts should be protected from exposure to sunlight, air, and moisture, by being kept in tightly-covered glass or earthenware containers, and should be stored in a cool, dark place.

"*Powdered extracts* differ from pilular extracts in that they are dry and prepared either as fine or granular powders. They are more generally used than pilular extracts because they can be more accurately weighed, more easily dispensed, and more conveniently preserved. These should be preserved in tightly-stoppered, small, wide-mouthed, amber-colored bottles, and stored in a cool, dry place." *U. S.*

Extracts of the pilular character, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather or a piece of bladder. The application of alcohol to the surface has a tendency to prevent mouldiness. Should the extract become too moist, it may be dried by means of a water bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner and incorporating with it a little distilled water.

When extracts which are too soft are subjected to a moderate temperature, fermentation or molding may set in; E. Cocardas describes the various forms of micro-organisms which are found in such extracts, and concludes that the ferment causes them to undergo changes similar to those effected by heat—*viz.*, the absorption of oxygen and the disengagement of carbon dioxide. (*P. J.*, 1886, p. 590.)

The addition of a little glycerin has been suggested to prevent the hardening of extracts; the U. S. directs the addition of glucose in the pilular extracts which will have a like effect. The U. S. VIII officially recommended the addition of glycerin. It is preferable to add a definite weight of the glycerin to the percolate. If it were added to the menstruum, owing to the variation in the yield of extracts from plants, some would be too soft, and at another time, in the case of a large yield of extract, the quantity of glycerin would be insignificant.

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; a good rule is to prepare them once a year; but the demand for extracts from fresh drugs has almost entirely ceased, as it has been found that properly dried drugs yield extracts of uniform strength.

Powdered extracts are always prepared by vacuum evaporation and they are stabilized by incorporating some inert material as starch, lactose or magnesium carbonate to prevent absorption of moisture and caking. They must be kept in tightly stoppered containers.

A. B. Lyons, of Detroit (1898), has introduced *scale extracts.* These do not, as a class, bear a definite relation to the drug; they are assayed, however, and acacia is used as a means of preserving their dry condition; they are easily pulverized, and are very convenient for dispensing.

EXTRACTUM ALOES. Br.

EXTRACT OF ALOES

Extrait d'Aloès, *Fr.;* Extractum Aloës, *P. G.;* Aloeextract, *G.;* Estratto di aloe acquoso, *It.*

"Aloes, in small fragments, 1000 *grammes;* Distilled Water, boiling, 10,000 *millilitres.* Add the Aloes to the Distilled Water and stir well until they are thoroughly mixed; set aside the mixture for twenty-four hours; decant; strain; evaporate the strained liquid to dryness at a temperature not exceeding 60° C." *Br.*

The object of this preparation is to afford an aloes purified from mechanical impurities. The process is based upon the British formulas for extracts of Barbados aloes and Socotrine aloes, formerly official. With an official purified aloes, the necessity for this preparation is not obvious. The U. S. P. IX dismissed Extract of Aloes and *Aloe Purificata,* but added tests for aloe which exclude inorganic impurities, gum, etc. (See *Aloe.*) An extract made with cold distilled water was formerly official in the German Pharmacopœia, as was also the vitriolated extract, "*Extractum Aloes Acido Sulfurico Correctum,*" made by suspending eight parts of extract of aloes in thirty-two parts of distilled water, adding drop by drop one part of pure sulphuric acid, and evaporating in a porcelain vessel to dryness.

Dose, one to five grains (0.06–0.3 Gm.).

EXTRACTUM BELLADONNÆ. U. S. (Br.)

EXTRACT OF BELLADONNA Ext. Bellad. [Extractum Belladonnæ Foliorum U. S. IX.]

"Extract of Belladonna yields not less than 1.18 per cent. and not more than 1.32 per cent. of the alkaloids of belladonna leaves. One Gm. of the Extract represents about 4 Gm. of belladonna leaves." *U. S.* "Dry Extract of Belladonna contains in 100 grammes 1 gramme of the alkaloids of Belladonna Leaves." *Br.*

Extractum Belladonnæ Siccum, *Br.;* Dry Extract of Belladonna; Extractum Belladonnæ Alcoholicum; Extractum Belladonnæ; Extrait de Belladone (Racine), *Fr. Cod.;* Spirituöses Tollkirschenextrakt, *G.;* Estratto di belladonna idroalcoolico, *It.;* Extracto alcoholico de belladona, *Sp.*

The U. S. directs this extract in two forms, Pilular Extract and Powdered Extract, so that the pharmacist might select the form that was best suited for dispensing. The pilular extract is used officially in the ointment. Both forms of the extract, however, are of the same strength.

"*Pilular Extract of Belladonna.*—Belladonna Leaves, in moderately coarse powder, 1000 Gm.; Glucose, Alcohol, Water, each, a sufficient quantity. Moisten the drug with sufficient of a mixture of 3 volumes of alcohol and 1 volume of water, and pack it firmly in a cylindrical percolator, then add enough menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum of the same strength, until the percolate measures 3000 cc. or until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue with frequent stirring at a temperature not exceeding 70° C. to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the mass, and to this add sufficient glucose to make the finished Extract contain 1.25 per cent. of the alkaloids of belladonna leaves. Mix thoroughly.

"**Assay.**—Proceed by Type Process D, taking 2 Gm. of Extract of Belladonna, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of belladonna (Proximate Assays)." *U. S.*

"*Powdered Extract of Belladonna.*—Belladonna Leaves, in moderately coarse powder, 1000 Gm.; Starch, dried at 100° C., Alcohol, each, a sufficient quantity. Moisten the drug with sufficient alcohol, and pack it in a cylindrical percolator, then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first 1000 cc. of percolate, and continue the percolation until the second percolate measures 1000 cc. or until the drug is exhausted. Transfer the second percolate to a suitable apparatus, and distil the alcohol at as low a temperature as practicable, until a residue measuring about 100 cc. remains, then add the reserved percolate, and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a shallow evaporating dish, rinse the flask or still with small portions of warm alcohol, adding the rinsings to the residue in the dish. Evaporate this to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. Then add 50 Gm. of the dried starch, and continue the heating at the same temperature, with frequent stirring until the mass is nearly dry. Now thoroughly incorporate an additional 20 Gm. of dried starch, and set the product aside in a current of warm air until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the powder, and add to this sufficient of the dried starch to make the finished Extract contain 1.25 per cent. of the alkaloids of belladonna leaves. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly.

"**Assay.**—Proceed as directed under the *Pilular Extract of Belladonna.*" *U. S.*

"Belladonna Leaves, in No. 40 powder, Alcohol (70 per cent.), of each, *a sufficient quantity.* Reduce ten grammes of the Belladonna Leaves to No. 60 powder and determine the proportion of alkaloids present by the process described under 'Belladonnæ Folia.' Moisten one thousand grammes of the Belladonna Leaves with two hundred and fifty millilitres of the Alcohol, pack firmly in a percolator and percolate with more of the Alcohol until four thousand millilitres of percolate have been obtained. Determine the proportion of total solids in the percolate by evaporating twenty millilitres, drying the residue at 80° C., and weighing. Determine also the proportion of alkaloids in the percolate, by the process described under 'Tinctura Belladonnæ,' employing forty millilitres of the percolate in the place of one hundred millilitres of the Tincture. Having thus determined the proportion of total solids and of alkaloids in the percolate, calculate the amount of each the remainder of the percolate will yield, and also the amount of the powdered Belladonna Leaves, the alkaloidal strength of which has also been determined, that must be added to afford a dry extract containing 1 per cent. of alkaloids. Add to the percolate a somewhat smaller amount of the powdered Leaves than calculation has shown to be necessary, recover the alcohol by distillation, and dry the residue in a shallow, flat, tared dish, first on a water-bath, and finally in a current of air at 60° to 80° C. Weigh the dish with its contents, calculate the additional amount of powdered Leaves that will be necessary, add this to the product of evaporation, transfer the whole to a dry, slightly warmed mortar and triturate carefully until thoroughly mixed. Pass the powdered Extract through a No. 20 sieve, transfer to a bottle which can be securely closed, and preserve in a cool dry place. Slightly moisten 5 grammes of the Extract with a mixture of 1 volume of *acetic acid* and 9 volumes of *alcohol* (70 per cent.), pack in a small percolator and percolate with the same menstruum, if necessary under increased air-pressure, until 50 millilitres of percolate have been collected. Then proceed as described under 'Tinctura Belladonnæ,' using 50 millilitres of percolate in the place of 100 millilitres of the Tincture. Examined by the foregoing process, Dry Extract of Belladonna is found to contain in 100 grammes 1 gramme of the alkaloids of Belladonna Leaves. *Limit of error* 0.05 gramme in excess or defect. This Dry Extract contains 1 per cent. of the alkaloids of Belladonna Leaves." *Br.*

Uses.—There is no physiological difference between the pilular and powdered extracts of belladonna. The former may be used in the preparation of pills or ointments, the latter wherever the action of belladonna is wished in the form of a powder or compressed tablet. For the conditions in which these extracts are useful, see under *Atropina.*

Dose, internally, from one-sixth to one-third of a grain (0.010–0.021 Gm.).

EXTRACTUM CANNABIS. U. S. (Br.)

EXTRACT OF CANNABIS Ext. Cannab. [Extractum Cannabis Indicæ, U. S. P. VIII]

"Extract of Cannabis, administered by the mouth to dogs, in doses not exceeding 0.004 Gm. for each kilogram of body weight of dog, produces a degree of incoördination equivalent to that caused by 0.03 cc., for each kilogram of body weight of dog, of the standard fluidextract of cannabis prepared as directed under *Cannabis.*" *U. S.*

Extractum Cannabis Indicæ, *Br.;* Extract of Indian Hemp, *Br.;* Extrait de Chanvre de l'Inde, *Fr. Cod.;* Indischer Hanfextrakt, *G.*

"Cannabis, in moderately coarse powder, 1000 Gm.; Alcohol, a sufficient quantity. Moisten the drug with sufficient alcohol, pack it firmly in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C., to a pilular consistence. Mix the mass thoroughly, and weigh it. Assay a portion of this extract as directed under *Cannabis,* and from the result thus obtained adjust the weight of the finished Extract by the addition of either storax or a substandard Extract of Cannabis to conform to the required biological standard.

"**Assay.**—Administer the Extract in gelatin capsules, proceeding as directed under *Cannabis.*" *U. S.* (See under *Cannabis* and Part III.)

"Exhaust Indian Hemp, in coarse powder, with Alcohol (90 per cent.) by the *percolation process;* recover the alcohol by distillation, and evaporate the residue to a soft extract." *Br.*

The continuation in the Br. Pharm. of the name of Indian Hemp is unfortunate because of the possibility of its being mistaken for the root of *Apocynum cannabinum,* which is also called Indian Hemp. Several mistakes have occurred through this unfortunate confusion of nomenclature.

Although there is some difference in the details of the two processes, the preparations of the U. S. and Br. Pharmacopœias are practically identical.

The preparation varies considerably in strength, so that it is wisest to begin with a small dose, one-quarter of a grain (0.016 Gm.), and rapidly increase the amount given until some effect is produced.

Dose, one-fourth to three-fourths of a grain (0.015–0.045 Gm.).

Off. Prep.—Tinctura Cannabis Indicæ, *Br.;* Mistura Chlorali et Potassii Bromidi Composita, *N. F.*

EXTRACTUM CARNIS. N. F.

EXTRACT OF BEEF Ext. Carnis [Beef Extract]

"The residue obtained from fresh beef broth by evaporation at a low temperature." *N. F.*

In its preparation the sound fresh meat is usually cut into small pieces, the appropriate amount of water is added, and the mixture placed in a vessel which may be closed to prevent the escape of any aqueous vapor and permit the application of slight pressure. After digestion for several hours in this apparatus, with occasional stirring, the liquid portion is poured off, the solid material gently pressed to separate any remaining liquid, then cooled to remove fat, and afterward strained. The clear liquid is afterwards evaporated in vacuo to the consistence of a pasty mass. Bones and tendons are not used as they introduce gelatin which is looked upon as an adulterant. It is usually spoken of as the *Liebig type of beef extract.*

Description and Physical Properties.—" A yellowish brown to dark-brown, slightly acid, pasty mass, having an agreeable meat-like odor and taste.

" Twenty-five Gm. of Extract of Beef, diluted with 250 cc. with distilled water, yields a nearly clear solution, free from sediment. Separate portions of this solution respond to the following tests: Boil 10 cc. of the solution for one minute with 1.5 Gm. of purified animal charcoal, add distilled water to replace that lost by evaporation and filter; the filtrate produces no blue coloration when one drop is added to three drops of a solution of diphenylamine (1 in 100) in concentrated sulphuric acid (*nitrate*). Distribute 10 cc. of the solution over dry sand or asbestos, and dry to constant weight in a flat-bottomed porcelain dish in an oven at a temperature of 105° C.; it yields a residue of not less than 0.75 Gm., equivalent to 75 per cent. of solids in the original Extract. Incinerate the residue from 10 cc. of the solution obtained in the preceding test; the ash does not exceed 30 per cent. of the residue, nor does the sodium chloride in the ash exceed 10 per cent. of the residue when determined as directed under the Assay for chlorides. To 100 cc. of the solution contained in a 500 cc. Kjeldahl flask, add 5 Gm. of barium carbonate and 100 cc. distilled water and, using a connecting bulb, distil 100 cc. into 10 cc. of half-normal hydrochloric acid. Titrate the excess of acid, using cochineal T.S. as indicator, and from the acid consumed by the distillate, calculate the percentage of nitrogen as ammonia. This does not exceed 0.35 per cent. of the total solids. Transfer 25 cc. of the solution to a 100 cc. Erlenmeyer flask, add 50 cc. of alcohol and shake the mixture thoroughly. When the precipitate has subsided, filter, collect the precipitate upon a 9 cm., counterpoised filter, wash the precipitate three times with a mixture of two volumes of alcohol and one volume of distilled water and then dry it to constant weight at 105° C. The weight of this precipitate does not exceed 10 per cent. of the total solids. (Reserve the filtrate and washing for the following determination of nitrogen.) To an aliquot portion of the alcoholic filtrate from the preceding test corresponding to 1 Gm. of the alcohol soluble solids, add 4 cc. of sulphuric acid and evaporate to dryness in a 500 cc. Kjeldahl flask. Determine the nitrogen by the Gunning-Kjeldahl method. The amount of nitrogen thus found is not less than 0.06 Gm." *N. F.*

The chief constituents present from the meat are *creatin, creatinin, xanthin, carnin,* and *carnic acid.* Under the name of *extract of beef* or *meat extract* products are found upon the market which probably are made by boiling down the liquor in which corned beef has been "cured" or "pickled." This is evidenced by the high proportion of salt and saltpeter which is found in some of these commercial products.

Uses.—As most of the protein of meat is precipitated by boiling and as the fat is deliberately rejected by the cold filtration of meat extract it is manifest that the final preparation can contain very little of the nutritional value of the meat. It is possible that the xanthin derivatives contained in this product may have a slight stimulating effect upon the system but the chief value of this preparation lies in its flavor which tends to excite appetite and thereby improve digestion.

Off. Prep.—Elixir Carnis et Ferri, *N. F.*

EXTRACTUM CASCARÆ SAGRADÆ.
U. S. (Br.)

EXTRACT OF CASCARA SAGRADA Ext. Casc. Sagr.
[Extractum Rhamni Purshianæ, U. S. VIII, Powdered Extract of Cascara Sagrada]

" *One gramme* of the Extract represents *three grammes* of cascara sagrada." *U. S.*

Extractum Cascaræ Sagradæ Siccum, *Br.;* Dry Extract of Cascara Sagrada; Extrait de Cascara Sagrada, *Fr. Cod.;* Cascara Sagrada-Extrakt, Amerikanisches Faulbaumrinden-extrakt, *G.;* Extracto alcoholico de cascara sagrada, *Sp.*

" Cascara Sagrada, in coarse powder, 900 Gm.; Starch, dried at 100° C., Boiling Water, each, a sufficient quantity, to make 300 Gm. Mix the cascara sagrada with 4000 cc. of boiling water, and macerate the mixture during three hours. Then transfer it to a metallic percolator, allow it to drain, and pour on boiling water until the percolate measures 5000 cc. or the drug is exhausted. Evaporate the percolate to dryness on a water or steam bath, reduce the extract to a fine powder, weigh it, and add sufficient of the dried starch to make the product weigh 300 Gm. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly." *U. S.*

" Exhaust Cascara Sagrada, in No. 20 powder, with Distilled Water by the *percolation process;* evaporate the percolate to dryness on a water-bath." *Br.*

The U. S. preparation is made to represent a definite proportion of the drug (4 to 1), by adding magnesium oxide, and is slightly weaker than that of the Br.

It well represents the virtues of the bark, and furnishes a good means of administering this purgative in pilular form.

Dose, from two to eight grains (0.13–0.5 Gm.).

Off. Prep.—Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ, *N. F.*

EXTRACTUM COLCHICI. U. S., Br.

EXTRACT OF COLCHICUM Ext. Colch. [Extractum Colchici Cormi, U. S. IX. Powdered Extract of Colchicum Corm]

"Extract of Colchicum yields not less than 1.25 per cent. and not more than 1.55 per cent. of colchicine. One Gm. of the Extract represents about 4 Gm. of colchicum corm." *U. S.*

Extractum Colchici Radicis, *U. S.*, 1890; Extrait de Colchique acetique, *Fr.;* Zeitlosen Essigextrakt, *G.*

"Colchicum Corm, in fine powder, 1000 Gm.; Alcohol, Purified Petroleum Benzin, Starch, dried at 100° C., each, a sufficient quantity. Moisten the colchicum corm with sufficient alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the drug and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the percolate measures 2000 cc. or until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable until a residue measuring about 150 cc. remains in the still. Transfer this residue to a flask or separator, using small portions of warm alcohol to rinse the still, and add the rinsings to the residue in the flask. When it has cooled, add 250 cc. of purified petroleum benzin, and shake the mixture thoroughly for several minutes. Allow the liquids to separate, and decant the benzin layer as closely as possible, again add to the residue 150 cc. of purified petroleum benzin, agitate, decant the benzin layer as before, repeat the washing with 100 cc. of purified petroleum benzin, and reject the benzin washings. Transfer the fat-free residue to a shallow evaporating dish, rinse the flask with small portions of warm alcohol, add the rinsings to the residue in the dish, and evaporate on a water bath to a thick extract. To this add 50 Gm. of the dried starch, mix well, spread the mixture on glass plates, and continue the drying in a current of warm air at a temperature not exceeding 70° C. until thoroughly dry. Reduce the product to a fine powder, and weigh it. Assay a portion of this product as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloid in the remainder of the powder, and add to this sufficient of the dried starch to make the finished Extract contain 1.4 per cent. of colchicine. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly.

"**Assay.**—Place 6 Gm. of Extract of Colchicum in a 500 cc. flask containing 290 cc. of distilled water, mix well, add 10 cc. of solution of lead subacetate, and agitate the mixture frequently during one hour. Filter off 200 cc. and proceed as directed under *Colchici Semen* assay, beginning with the word 'Add.'" *U. S.*

"Crush fresh Colchicum Corms, deprived of their coats; press out the juice; allow the feculence to subside, decant; heat the clear liquid to 100° C.; strain through flannel, and evaporate at a temperature not exceeding 70° C. to a soft extract." *Br.*

The U. S. VIII extract was an acetic extract of the corm, but in the present process the acetic acid is omitted. The British extract is made by evaporating the juice of fresh corms.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims (0.3 cc.) or more. It is made by expressing the fresh corm, allowing the juice to stand for forty-eight hours that the starchy matter may subside, then adding one-fourth of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

As the fresh colchicum corm is rarely to be had in this country, the U. S. Pharmacopœia employs the dried corm; its process, if properly conducted, will afford a very efficient extract. In preparing this extract according to the British process, by expression from the recent corm, there will be experienced some inconveniences, which would seem to render the U. S. process under all circumstances preferable. (*P. J.*, xiii, 62.)

Dose, from one-fourth to one grain (0.016–0.065 Gm.).

EXTRACTUM COLOCYNTHIDIS. U. S.

EXTRACT OF COLOCYNTH Ext. Colocynth. [Powdered Extract of Colocynth]

"One Gm. of the Extract represents 4 Gm. of colocynth." *U. S.*

Extractum Colocynthidis Alcoholicum; Extrait de Coloquinte, *Fr. Cod.;* Extractum Colocynthidis, *P. G.;* Koloquintenextrakt, *G.;* Estratto di coloquintide idroalcoolico, *It.*

"Colocynth, in coarse powder, 1000 Gm.; Diluted Alcohol, Starch, dried at 100° C., each, a sufficient quantity, to make 250 Gm. Moisten the drug with 2000 cc. of diluted alcohol, and macerate it in a closed vessel for twenty-four hours, then transfer the moist drug to a cylindrical percolator, shake it down evenly without packing, and gradually pour diluted alcohol upon it, allowing the percolation to proceed slowly until the percolate measures 5000 cc. or until the drug is practically exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue to dryness on a water or steam bath. Reduce the product to a fine powder, weigh it, and add sufficient of the dried starch to make the product weigh 250 Gm. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly." *U. S.*

The colocynth should always be deprived of its seeds, following the directions of the U. S. Pharmacopœia, before being submitted to the action of the menstruum. Boiling water extracts such a large amount of pectin and mucilage from colocynth that either the decoction or the hot infusion gelatinizes on cooling, and the extract made by means of it is therefore loaded with inert matter, and, besides, is liable to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence many years ago the London College, following in this respect the old French Codex, directed, in the last edition of its Pharmacopœia, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has accordingly been adopted in the U. S. Pharmacopœia process, while in the British Pharmacopœia the simple extract has been discarded altogether. The chief, if not exclusive, use of the alcoholic extract is in the preparation of the compound extract.

This is an active, but harsh purgative and is rarely employed except in combination with other cathartics.

Dose, one-half grain (0.032 Gm.).

Off. Prep.—Extractum Colocynthidis Compositum, *U. S.*

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U. S., Br.

COMPOUND EXTRACT OF COLOCYNTH Ext. Colocynth. Co. [Powdered Compound Extract of Colocynth]

Extrait de Coloquinte composé, *Fr.;* Zusammengesetzten Koloquintenextrakt, *G.*

"Extract of Colocynth, 160 Gm.; Aloe, 500 Gm.; Cardamom Seed, in fine powder, 50 Gm.; Resin of Ipomœa, in fine powder, 140 Gm.; Soap, dried and in powder, 150 Gm.; to make 1000 Gm. Triturate the ingredients until the product is reduced to a fine powder. Pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly." *U. S.*

"Colocynth Pulp, 150 *grammes;* Extract of Aloes, 300 *grammes;* Scammony Resin, 100 *grammes;* Curd Soap, in powder, 75 *grammes;* Cardamom Seeds, in powder, 25 *grammes;* Alcohol (60 per cent.), 4000 *millilitres.* Macerate the Colocynth Pulp in the Alcohol for four days; press out the tincture; recover the alcohol by distillation; evaporate to dryness; add the Extract of Aloes, Scammony Resin, and powdered Cardamom Seeds; powder; mix the powder with the Curd Soap." *Br.*

The U. S. X preparation differs from the former in that Ipomea resin has been substituted for Scammony. The Br. Pharm. (1914) directs Extract of Aloes instead of Barbados Aloes, and decreased the proportion of soap from four to three ounces. The object of the soap is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the gastric juices. It may possibly also serve the purpose of modifying the action of the aloes. In the U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while if given uncombined, it may be readily made into pills by suitable additions. The plan of having the powders simply mixed was liable to the objection that the mixture was not likely to be so thoroughly effected as to obtain a uniform result, and hence the U. S. Pharm., 1880, adopted Squibb's suggestion, to melt together all the ingredients unpowdered, except the cardamom, add a little alcohol, and, when the mixture is thoroughly made, to stir in the powdered aromatic, and finally to reduce the whole to a fine powder. The U. S. P. X, however, relies upon trituration as an assurance of thorough commingling.

This extract is an energetic cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, calomel, etc., with one or more of which it is often united in prescription.

Dose, as a laxative, one to two grains (0.065–0.13 Gm.); as a purgative, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Pilulæ Hydrargyri Chloridi Mitis Compositæ, *U. S.;* Pilulæ Catharticæ Vegetabiles, *N. F.;* Pilulæ Antidyspepticæ, *N. F.;* Pilulæ Laxativæ Post Partum, *N. F.*

EXTRACTUM ERGOTÆ. Br.

EXTRACT OF ERGOT Ext. Ergot.

Extractum Hæmostaticum; Ergotin, *Br.*, 1898; Extrait d'Ergot de Seigle, *Fr. Cod.;* Extractum Secalis cornuti, *P. G.;* Mutterkornextrakt, *G.;* Estratto di segala cornutta, *It.;* Extracto Acuoso de Cornezuelo de Centeno, *Sp.*

"Ergot, crushed, 1000 *grammes;* Distilled Water, 7500 *millilitres;* Alcohol (90 per cent.), 650 *millilitres.* Macerate the Ergot with *five thousand millilitres* of the Distilled Water for twelve hours; strain; repeat the maceration with the remainder of the Distilled Water; strain; press; evaporate the mixed liquids to *five hundred millilitres;* add the Alcohol; set aside for three days, stirring occasionally; filter; evaporate the filtrate to a soft extract." *Br.*

Because of the injurious effect of heat on the active principles of ergot, it is almost impossible to concentrate the percolates to an extract consistency without largely destroying their physiological properties, and at the last revision of the Pharmacopœia this preparation was very properly omitted. The British extract being made with an aqueous menstruum, cannot contain all the active principles of the drug as some are insoluble in water (see *Ergota*).

Dose, from two to eight grains (0.12–0.5 Gm.).

Off. Prep.—Injectio Ergotæ Hypodermica, *Br.*

EXTRACTUM EUONYMI. Br.

EXTRACT OF EUONYMUS

Dry Extract of Euonymus; Extract of Wahoo; Extrait d'Evonymus atropurpureus, *Fr. Cod.;* Extrait de Fusain Américaine, *Fr.;* Spindelbaumextrakt, Spillbaumrindenextrakt, *G.*

"Exhaust Euonymus Bark in No. 20 powder with Alcohol (45 per cent.) by the *percolation process.* Evaporate the percolate and thoroughly dry the residue. Powder the product as far as possible and mix it with one-fourth of its weight of Calcium Phosphate, continuing the drying and powdering until a sufficiently dry preparation is obtained; transfer this to a well-closed bottle." *Br.*

The N. F. preparation (see Part III) is diluted with starch and made to represent four times its weight of crude drug, whereas the Br. is mixed with an amount of calcium phosphate proportional to the extract.

This extract was not admitted to the U. S. P. IX, but was retained in the Br. Pharm. (1914) and introduced into the National Formulary (see Part III) which directs the percolation of euonymus in No. 40 powder with alcohol 4 volumes and water 1 volume. The percolate is evaporated or distilled and the residue dried and mixed with dried starch so that 1 Gm. of the extract represents 4 Gm. of euonymus. On account of the reports of physicians of cumulative effects the following note was inserted: "CAUTION—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." *N. F. IV.* Dry and powdered extract of euonymus is frequently but erroneously termed "*euonymin*" (see under *Euonymus*).

Dose, one to three grains (0.065 to 0.2 Gm.).

EXTRACTUM FELLIS BOVIS. U. S. (Br.)

EXTRACT OF OXGALL Ext. Fel. Bov. [Powdered Extract of Oxgall]

"One Gm. of the Extract represents 8 Gm. of oxgall." *U. S.*

Fel Bovinum Purificatum, *Br.;* Purified Ox Bile; Fel Tauri Depuratum; Extractum Fellis Bovini; Extrait de Fiel de Bœuf, *Fr. Cod.;* Gereinigte Ochsengalle (Rindsgalle), *G.;* Bile cristallizzata di platner, *It.;* Hiel de toro preparada, *Sp.*

"*Oxgall,* 800 Gm.; Alcohol, 1500 cc.; Starch dried at 100° C., a sufficient quantity, to make 100 Gm. Add 1000 cc. of alcohol slowly and with agitation to the oxgall contained in a bottle of sufficient size. Allow the mixture to stand for two days, and then decant the liquid portion. Wash the residue in the bottle with an additional 500 cc. of alcohol, decant the liquid portion, mix it with the liquid first separated, and filter. Recover the alcohol from the filtrate by distillation, transfer the residue to a shallow dish, and evaporate it to a thick extract at a temperature between 75° and 80° C. Spread this extract on glass plates, and continue the drying by exposure to warm air at a temperature not exceeding 70° C. until thoroughly dry. Reduce the product to a fine powder, weigh it, and add sufficient of the dried starch to make the product weigh 100 Gm. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly. The use of copper apparatus in the preparation of this Extract should be avoided." *U. S.*

"Evaporate five hundred *millilitres* of fresh ox bile to one-fourth of its volume; shake this liquid with twice its volume of Alcohol (90 per cent.); set the mixture aside until the solid matter has subsided; decant the clear solution, and filter the remainder, washing the filter and contents with a little more Alcohol (90 per cent.). Distil off most of the alcohol from the mixed liquids, and evaporate the residue in a porcelain dish, on a water-bath, to the consistence of a firm extract." *Br.*

The object of this preparation is to furnish purified concentrated oxgall in a condition in which it can be satisfactorily prescribed for internal administration. The addition of alcohol to the concentrated liquid is made for the purpose of separating albuminous matter.

Properties.—"A yellowish-green hygroscopic substance, having a taste partly sweet and partly bitter, soluble in *water* and in *alcohol* (90 per cent.). 1 millilitre of an aqueous solution (1 in 100) in which 0.1 gramme of *refined sugar* has been dissolved, gradually acquires a deep violet color when mixed with 10 millilitres of *syrupy phosphoric acid* and heated in a water-bath. Its aqueous solution on the addition of twice its volume of *alcohol* (90 per cent.) gives no precipitate (absence of unpurified ox bile)." *Br.*

Refined oxgall, much used by painters, is prepared, according to Gray, in the following manner. Take of "fresh oxgall, one pint; boil, skim, and add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months; then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colorless."

This extract represents practically a mixture of sodium glycocholate and sodium taurocholate contaminated with traces of fatty and soapy matters. (See *Fel Bovis.*) The direction to add starch in sufficient quantity in this extract is unfortunate. The therapeutic activity of bile resides in its solid matters and as the proportion of these varies greatly it is manifest that the extract should be standardized, not as it is at present, to represent a certain amount of fresh bile, but to represent a proportion of dried bile, *i.e.,* of the biliary solids.

Uses.—By the ancients bile was a very highly esteemed remedy and was used in a great variety of conditions. It, however, fell into desuetude and for many years was rarely employed. Recently it has again come largely into favor but for a very different class of disorders. Its most frequent use to-day is to replace or augment the hepatic secretions when these for any reason are lacking. While the exact rôle that the bile plays in the intestinal tract is not clearly understood, it is well established that it plays an important part in digestion, especially of the fatty foods.

When introduced into the circulation bile has a depressant effect upon the heart muscle leading to a reduction in the blood pressure and slowing of the pulse. Whether or not the slowing of the pulse is partly indicative of inhibitory stimulation is at present under dispute, but it seems well established that after large doses, at least, the slowing of the pulse is the result of a direct action upon the heart muscle. According to Meltzer and Salant (*J. Ex. M.*, viii), there are present in the bile both an excito-motor and depresso-motor principle. Bile has long been recognized as the most powerful stimulant to the secretory activity of the liver which we possess, but according to Shaffer (*A. J. Phys.*, 1907, xvii, p. 389), this is not indicative of a true excitation of the hepatic cells but is simply that, after its injection, the blood contains the preformed material for excretion and that the increase in the output of the bile solids does not exceed the dose which was injected. Hooper and Whipple (*J. A. M. A.*, 1917, lxix, 386) have found that taurocholic acid has a strong cholagogue action but that glycocholic acid, while causing a moderate increase in the flow of bile, lessens the output of the bile pigments. The presence of bile in the intestinal tract has by some been held to diminish the multiplication of bacteria, but there is no convincing evidence of such an action. It increases peristaltic movements in the large intestines but appears to diminish those of the upper bowel.

Oxgall has been found useful in a variety of conditions in which there is a diminution in the amount of bile in the intestinal tract, as for instance in *catarrhal cholangitis,* and *hepatic torpor.* In *gall stones* while it may improve the digestion by offering a necessary ferment there is no sufficient reason to believe that it will aid the solution of the stones. It is also a valuable agent in the treatment of certain forms of *chronic constipation,* not solely because of its own action in increasing the peristalsis of the colon, but because its presence in the intestines is essential for the action of many of the cathartics. Cholesterin, which is one of the ingredients of bile, has the power of neutralizing certain poisons such as tetanotoxin, sapotoxin, and snake venom, and may perhaps prove clinically useful for this purpose. It should be noted, however, that as cholesterin is scarcely soluble in cold alcohol, the extract will contain not more than traces of it.

The daily amount of bile secreted by an ordinary man varies between two hundred and four hundred cc. (6.7–13.3 fluidounces), containing from 1 to 3 per cent. of solids. If there is a marked reduction in the secretion of bile it is evident that the pharmacopœial dose is far too small to have any effect. Because of a supposed injurious action upon gastric digestion various recommendations have been made for administering bile in the form that it will pass through the stomach; among these may be mentioned the use of keratin coated or salol coated pills, and by mixing with spermaceti. We think, however, that the liability of disturbance of the stomach by this agent has been over-estimated.

Among the proprietary preparations of bile may be mentioned: *bilein,* which is marketed in pills ranging from one-twelfth to one-fourth of a grain (0.05–0.016 Gm.); *cholalin,* a yellow powder, dose one-fourth to one-half grain (0.016–0.032 Gm.); *glycotauro,* dose five to ten grains (0.32–0.65 Gm.); *ovogall,* a yellowish powder said to consist of a combination with egg albumen, dose eight to fifteen grains (0.5–1 Gm.); *sodium choleinate,* dose eight to fifteen grains (0.5–1 Gm.); *cholesterin* may be given in doses of fifteen to twenty-five grains (1.0–1.7 Gm.).

Dose, of extract of bile, two to eight grains (0.12–0.5 Gm.).

EXTRACTUM GENTIANÆ. Br.

EXTRACT OF GENTIAN Ext. Gentian.

Extrait de Gentiane, *Fr. Cod.;* Extractum Gentianæ, *P. G.;* Enzianextrakt, *G.;* Estratto di genzian acquoso, *It.;* Extracto acuoso de genciana, *Sp.*

"Infuse Gentian Root in ten times its weight of Distilled Water for two hours; boil for fifteen minutes; pour off; press; strain; evaporate the liquid to a soft extract." *Br.*

This preparation has been dismissed from the U. S. X.

As ordinarily procured, the extract of gentian has an agreeable odor, is very bitter, and of a dark brown color approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations; but the practice of some pharmacists of using it indiscriminately as a pill excipient is deserving of severe censure.

Dose, from two to eight grains (0.12–0.5 Gm.).

Off. Prep.—Pilulæ Antiperiodicæ, *N. F.;* Pilulæ Ferri, Quininæ, Aloes, et Nucis Vomicæ, *N. F.*

EXTRACTUM GLYCYRRHIZÆ. U. S.

EXTRACT OF GLYCYRRHIZA Ext. Glycyrrh.
[Extract of Licorice]

"The commercial Extract of Glycyrrhiza." *U. S.*

Extractum Liquiritiæ; Liquorice, Licorice; Extrait de Réghsse, *Fr. Cod.;* Suc de Réglisse, Sucre noir, *Fr.;* Succus Liquiritiæ, *P. G.;* Lakriz, Lakritzensaft, Süssholzsaft, *G.;* Estratto diliquirizia, Sugo di liquirizia, Legorizia, Regolizia, *It.;* Extracto acuoso de regaliz, Regaliza en ballos, *Sp.*

Licorice is an article of export from the north of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of the *G. glabra,* having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water until the liquor is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract, thus prepared, is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

The British extract of licorice is nearly the same as the "pure extract" of the U. S.

Much licorice is prepared in Calabria, according to Fée, from the *G. echinata,* which abounds in that country. The process is essentially the same as that just described, but conducted with greater care, and the Italian licorice is purer and more valuable than the Spanish. It is in cylinders, generally somewhat smaller than the Spanish, and usually stamped with the manufacturer's brand. Most of the extract brought to this country comes from Messina and Catania in Sicily and Naples, from Seville and Saragossa in Spain, and from Smyrna in Turkey. Perhaps in no other part of the world is more licorice consumed than in the United States, from four to five thousand tons having been imported annually before 1860; but the article is now made on an extensive scale in this country, very successfully, with the best modern appliances, and of such good quality as to have almost driven the foreign article out of the market. The principal use of Extract of Licorice is in the manufacture of chewing tobacco, that in the form of rolls as sold by the druggist being a comparatively small portion of the whole amount consumed.

Crude Licorice, Licorice Paste, or *Licorice Mass,* as it is variously termed, is found in the market in cases ranging from two hundred and fifty to four hundred pounds, of a hard pilular consistence and, as its name implies, in a mass, which has been run into the case while hot and then allowed to cool.

Licorice is usually in cylindrical rolls, somewhat flattened, and usually packed in bayleaves. When good, it is black, dry, brittle, breaking with a shining fracture, of a peculiar sweet and slightly acrid or bitterish taste, and almost entirely soluble, when pure, in boiling water.

Description and Physical Properties.—"In flattened, cylindrical rolls or in masses, of a glossy black color externally; fracture brittle, sharp, smooth, conchoidal; taste characteristic and sweet. When pulverized it yields a brown powder.

"Not less than 60 per cent. of Extract of Glycyrrhiza is soluble in cold water. The yield of ash does not exceed 8 per cent." *U. S.*

Neumann obtained 460 parts of aqueous extract from 480 parts of Spanish licorice. It is, however, considerably less soluble in cold water. In different commercial specimens examined by Chevallier he found from 9 to 50 per cent. of insoluble matter. (*J. P. C.,* xxx, 429.) This is by no means, however, always impurity. In the preparation of the extract by decoction, a portion of matter originally insoluble, or rendered so by decoction, is taken up, and is, in fact, necessary to the proper constitution of the licorice. When this is prepared with cold water, or even with hot water by simple displacement, the extract attracts moisture from the air, becomes soft, and loses the characteristic brittleness of the drug. The additional substances taken up in decoction serve to protect the extract against this change. Delondre has obtained the same result by using steam as the solvent. He prepares from the root an excellent licorice, having all the requisite qualities of color, taste, and permanence, by passing steam, in suitable vessels, through the coarse powder of the root. The vapor thoroughly penetrates the powder, and is drawn off as it condenses. With about 500 lbs. of the root, this treatment is continued for twelve hours, and repeated at the end of five days. The liquors are collected, decanted, clarified with about 4 lbs. of gelatin, and quickly evaporated. After being put into the form of cylinders, the extract is kept for ten days in a drying room, at a temperature of 25° C. A bitter or empyreumatic taste is a sign of inferior quality in licorice. As ordinarily found in commerce, it requires to be purified. (See *Extractum Glycyrrhizæ Purum.*)

Licorice contains *glycyrrhizin,* a glucosidic acid, partly free and partly in combination with ammonia, to which combination the characteristic sweet taste of licorice is due. The glycyrrhizin, which is the acid ammonium salt of *glycyrrhizic acid,* $C_{44}H_{62}NO_{18}NH_4$, when boiled with dilute acids decomposes into *glycyrrhetin,* $C_{32}H_{47}NO_4$, and *parasaccharic acid,* $C_6H_{10}O_8$.

Mellor (*A. J. P.,* 1898, 23, 54, 136) examined twelve samples, of which the one highest in glycyrrhizin content was a Greek licorice with 27.78 per cent., and the lowest a Spanish with 5.28 per cent. of glycyrrhizin. Of insoluble matter, the highest was a Spanish with 36.52 per cent., and the lowest a Greek with 5.95 per cent. The average yield, however, was strongly in favor of American licorice.

Several methods have been suggested for determining the proportion of glycyrrhizin; one of these is as follows: 2 Gm. of the licorice are dissolved in 10 cc. of hot water and after cooling precipitated with 50 cc. of alcohol. The precipitate is allowed to settle, or separated by means of a centrifuge, then washed with 80 per cent. alcohol and the washings added to the alcoholic extract. This is then evaporated in vacuo on a water bath and the extract dissolved in 30 cc. of water, cooled to 15° C., the glycyrrhizin precipitated by adding 3 cc. of 10 per cent. sulphuric acid. The glycyrrhizin is dissolved in 95 per cent. alcohol, filtered and evaporated to dryness. (See Housemann, *A. J. P.,* 1921, xciii, 481). Some authorities recommend washing the glycyrrhizin with ice water, in which it is practically insoluble, before weighing. For other methods see Luiz, *A. Pharm.,* 1916, ccliv, 134 and Evans' Sons, Lescher and Webb method. (*Proc. A. Ph. A.,* 1911, 57.)

W. Zimmermann has studied various methods of glycyrrhizin assay and other factors for determining the quality of licorice extract (*Ap. Ztg.*, through *Chem. Abstr.*, 1919, xiii, 2962). He states that the water content of the extract should not exceed 17 per cent., ash not more than 11 per cent. and glycyrrhizin content not less than 10 per cent. The water insoluble portion should not exceed 25 per cent. and should be examined microscopically for specific adulterants. The *Pontefract cakes* are small lozenges of licorice made in the vicinity of Pontefract, England.

Uses.—Licorice has some demulcent property and is a popular addition to various lozenges. In large quantities it is somewhat laxative. Its most important rôle in medicine, however, is for the purpose of disguising the taste or covering the acrimony of various drugs such as quinine or ammonium chloride. It is also used to impart consistency to pills and troches.

Off. Prep.—Trochisci Ammonii Chloridi, *U. S.*

EXTRACTUM GLYCYRRHIZÆ PURUM.
U. S. (Br.)

PURE EXTRACT OF GLYCYRRHIZA
Ext. Glycyrrh. Pur.

Extractum Glycyrrhizæ, *Br.;* Extract of Liquorice; Extractum Glycyrrhizæ Depuratum, Succus Liquiritiæ Depuratus; Extrait de Réglisse, *Fr.;* Succus Liquiritiæ depuratus, *P. G.;* Gereinigter Süssholzsaft, Reines Lakriz, *G.;* Extracto Acuoso de Regliz, *Sp.*

"Glycyrrhiza, in coarse powder, 1000 Gm.; Boiling Water, a sufficient quantity. Moisten the drug with sufficient boiling water, transfer the moist drug to a metallic percolator, and percolate with boiling water until the glycyrrhiza is exhausted. Promptly evaporate the percolate to a pilular consistence on a water bath." *U. S.*

"Liquorice Root, in No. 20 powder, 1000 *grammes;* Chloroform Water, 5000 *millilitres.* Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C.; strain through flannel; evaporate to a soft extract." *Br.*

The necessity for a pure extract of licorice must be apparent to every pharmacist; the very variable quality of the commercial extract has frequently led to disappointment. The official process affords a preparation which is unexceptionable, the ammonia rendering the glycyrrhizin soluble, yet care must be taken in its evaporation, as it is very easily injured by too much heat, which gives it an empyreumatic taste, destroying at once its usefulness as an agreeable adjuvant. Extract of licorice is incompatible with acids of all kinds which precipitate the glycyrrhizin.

Off. Prep.—Mistura Glycyrrhizæ Composita, *U. S.;* Mistura Ammonii Chloridi, *N. F.*

EXTRACTUM HYOSCYAMI. U. S., Br.

EXTRACT OF HYOSCYAMUS Ext. Hyosc.

"Extract of Hyoscyamus yields not less than 0.22 per cent. and not more than 0.28 per cent. of the alkaloids of hyoscyamus. One Gm. of the extract represents about 4 gm. of hyoscyamus." *U. S.* "Extract of Hyoscyamus contains in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves." *Br.*

Extract of Henbane; Extrait de Jusquiame, *Fr. Cod.;* Extractum Hyoscyami, *P. G.;* Bilsenkrautextrakt, *G.;* Estratto di giusquiamo idroalcoolico, *It.;* Extracto alcoholico de beleno, *Sp.*

"*Pilular Extract of Hyoscyamus.*—Hyoscyamus, in moderately coarse powder, 1000 Gm.; Glucose, Alcohol, Water, each, a sufficient quantity. Moisten the drug with sufficient of a mixture of 3 volumes of alcohol and 1 volume of water, pack it firmly in a cylindrical percolator, and add enough menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more of the same menstruum until the drug is exhausted. Recover the alcohol by distillation, and evaporate the residue, with frequent stirring, at a temperature not exceeding 70° C., until it is reduced to a pilular consistence. Mix the mass thoroughly, and weigh it. Assay a portion of this extract as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the mass, and to this add sufficient glucose to make the finished Extract contain 0.25 per cent. of the alkaloids of hyoscyamus. Mix thoroughly." *U. S.*

Assay.—"Proceed by Type Process D, taking 5 Gm. of Extract of Hyoscyamus, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of hyoscyamus (Proximate Assays)." *U. S.*

"*Powdered Extract of Hyoscyamus.*—Hyoscyamus, in moderately coarse powder, 1000 Gm.; Starch, dried at 100° C.; Alcohol, each, a sufficient quantity. Moisten the drug with sufficient alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first 1000 cc. of percolate, and continue the percolation until the drug is exhausted. Transfer the weaker percolate to a suitable apparatus, and distil the alcohol at as low a temperature as practicable until a residue measuring about 100 cc. remains, then add the reserved percolate and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a shallow evaporating dish, and rinse the flask or still with small portions of warm alcohol, adding the rinsings to the residue in the dish. Evaporate this to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. Then add 50 Gm. of the dried starch, and continue the heating at the same temperature, with frequent stirring, until the mass is nearly dry. Now thoroughly incorporate an additional 20 Gm. of the dried starch, and set the product aside in a current of warm air, until thoroughly dry. Reduce the product to a fine powder, and weigh it. Assay a portion of this product as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the powder, and add to this sufficient of the dried starch to make the finished Extract contain 0.25 per cent. of the alkaloids of hyoscyamus. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly.

" **Assay.**—Proceed as directed under *Pilular Extract of Hyoscyamus.*" *U. S.*

" Hyoscyamus Leaves, in No. 40 powder, Alcohol (70 per cent.), of each, *a sufficient quantity*. Reduce ten grammes of the Hyoscyamus Leaves to No. 60 powder, and determine the proportion of alkaloids present by the process described under 'Belladonnæ Folia.' Moisten one thousand grammes of the Hyoscyamus Leaves with two hundred and fifty millilitres of the Alcohol, pack firmly in a percolator, and percolate with more of the Alcohol until four thousand millilitres of percolate have been obtained. Determine the proportion of total solids in the percolate by evaporating twenty millilitres, drying the residue at 80° C., and weighing. Determine also the proportion of alkaloids in the percolate by the process described under 'Tinctura Belladonnæ.' Having thus determined the proportion of total solids and of alkaloids in the percolate, proceed as directed under 'Extractum Belladonnæ Siccum' to prepare a dry Extract of Hyoscyamus containing 0.3 per cent. of alkaloids. Examined by the process described under 'Extractum Belladonnæ Siccum,' Extract of Hyoscyamus is found to contain in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves. *Limit of error* 0.015 gramme in excess or defect." *Br.*

" This Extract may be used when the Extractum Hyoscyami of the International Agreement is required. It contains 0.3 per cent. of the alkaloids of Hyoscyamus Leaves." *Br.*

The strength is not quite the same, the U. S. P. requires not less than 0.22 per cent. nor more than 0.28 per cent. of alkaloids while the Br. Pharm., 1914, requires not less than 0.3 per cent. of alkaloids. For an account of the disadvantages of the extract from the fresh leaves see *U. S. Dispensatory,* 19th ed., p. 478.

Dose, from one-half to two grains (0.03–0.13 Gm.).

Off. Prep.—Pilulæ Carthartieæ Vegetabiles, *N. F.;* Pilula Colocynthidis et Hyoscyami, *Br.* (*N. F.*)*;* Pilulæ Laxativæ Post Partum, *N. F.*

EXTRACTUM KRAMERIÆ. Br.

EXTRACT OF KRAMERIA

Extract of Rhatany; Extractum Ratanhæ; Extrait d Ratanhia, *Fr. Cod.;* Ratanhaextrakt, *G.;* Estratto di ratania acquoso, *It.;* Extracto acuoso de ratania, *Sp.*

" Exhaust Krameria Root, in No. 10 powder, with Distilled Water by the *percolation process;* evaporate the percolate to dryness." *Br.*

A powdered extract of krameria is recognized by the N. F. (see Part III).

Extract of krameria should have a reddish-brown color, a smooth shining fracture, and a very astringent taste, and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed.

Dose, from five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Trochiscus Krameriæ, *Br.;* Trochiscus Krameriæ et Cocainæ, *Br.*

EXTRACTUM MALTI. U. S.

EXTRACT OF MALT Ext. Malt.

Essence (Extrait) de Malt, *Fr.;* Malzextrakt, *G.*

" Extract of Malt is obtained by infusing malt with water at 60° C., concentrating the expressed liquid at a temperature not exceeding 60° C., and adding 10 per cent., by weight, of glycerin. It contains dextrin, maltose, a small amount of glucose, and an amylolytic enzyme. Extract of Malt is capable of converting not less than five times its weight of starch into water-soluble sugars." *U. S.*

Description and Physical Properties.—" A sweet, viscous, light brown, liquid extract having an agreeable, characteristic odor. It is soluble in cold water, more readily soluble in warm water. Specific gravity: not less than 1.350 and not more than 1.430 at 25° C.

" **Assay.**—Mix a quantity of potato starch, purified as directed under *Pancreatinum,* equivalent to 5 Gm. of dried starch, in a beaker with 10 cc. of cold, distilled water. Add 140 cc. of boiling distilled water, and heat on a water bath with constant stirring for two minutes, or until a translucent, uniform paste is obtained. Cool to 40° C. in a suitable bath previously adjusted to this temperature. Add 20 cc. of a fresh solution of Extract of Malt at 40° C., prepared by dissolving 5 Gm. of Extract of Malt in sufficient distilled water to make 100 cc. of solution at 40° C., mix well, and maintain the same temperature for exactly thirty minutes, stirring frequently. A thin, nearly clear liquid is produced. Add at once 0.1 cc. of this liquid to a previously made mixture of 0.2 cc. of tenth-normal iodine and 60 cc. of distilled water. No blue or reddish color is produced." *U. S.*

Under the name of extract of malt, two distinct preparations were formerly found upon the market, the one being a liquid similar to beer, the other, the official extract prepared from malt, composed chiefly of dextrin and glucose, with some albumen and phosphates. The object of the U. S. process is to obtain all of the soluble principles of malt in a permanent form. To secure this, strict attention to the details of the process is necessary. Good extract of malt should contain no starch, have the consistence of thick honey, a brown color, and should be free from empyreumatic taste. A great deal of commercial extract of malt is said to be adulterated with glucose. A *dry extract of malt* has come into extensive use as an infant's food, made by artificially drying the thick syrupy extract. It is in the form of a straw-colored, coarse powder, and is given dissolved in milk or water.

Extract of malt is a viscid brown liquid with a characteristic empyreumatic flavor and sweet taste. It consists of from 45 to 55 per cent. of maltose, with smaller quantities of dextrin and protein, and contains in addition a characteristic enzyme, *diastase.* This ferment appears to act very much like the ptyalin of the saliva, converting starch into maltose; it differs from that enzyme, however, in that whereas ptyalin acts most rapidly at the body temperature (37° C.) the malt is most active at a temperature of about 55° C. Chittenden and Cummins have shown that the presence of either free acid or free alkalies interferes with the amylolytic properties of diastase.

Under the name of *Diastasum,* the U. S. IX recognized a mixture containing the active ferments of malt. It was capable of digesting 50 times its weight of starch and was officially described as follows: "Diastase occurs as a yellowish-white, amorphous powder or in translucent scales; odorless and tasteless. It converts starch into dextrin and maltose. Diastase gradually loses its amylolytic power on keeping; this power is destroyed by heating its solutions above 85° C., or by the addition of much acid and is diminished by the presence of acids or alkalies. Diastase is soluble in water, the solutions being more or less turbid; almost insoluble in alcohol.

"*Assay.*—Mix a quantity of potato starch, purified as directed under *Pancreatinum,* equivalent to 5 Gm. of dry starch, in a beaker with 10 mils of cold distilled water. Add 140 mils of boiling distilled water, and heat the mixture on a water bath with constant stirring for two minutes, or until a translucent, uniform paste is obtained. Cool the paste to 40° C. in a water bath previously adjusted to this temperature. Prepare a fresh solution of 0.1 Gm. of Diastase in 10 mils of distilled water at 40° C. and add it to the paste. Mix them well and maintain the same temperature for exactly thirty minutes, stirring frequently; a thin, nearly clear liquid is produced. Add at once 0.1 mil of this liquid to a previously made mixture of 0.2 mil of tenth-normal iodine V.S. and 60 mils of distilled water; no blue or reddish color is produced." *U. S. IX.*

Diastase is frequently found upon the market in an impure or adulterated condition, samples having been observed containing as much as 60 per cent. of starch. Much of the commercial diastase is variable in strength and frequently it is almost inert. *Takadiastase* is the name of a proprietary form of diastase which is not produced from malt but is produced by the growth of certain species of *Aspergillus* upon rice hulls or bran. In Japan takadiastase is used in the brewing industry as malt is used in other countries. Wahl has shown that malt contains a proteolytic as wel as an amylolytic ferment.

Uses.—The extract of malt is used in medicine for three purposes, first, as a highly nutritious and easily assimilable food in various states of *malnutrition;* secondly, for the purpose of increasing the digestion of starches in certain types of *dyspepsia.* In those rare cases where there is an organic deficiency of saliva, or in the more frequent condition where the patient is too lazy to masticate his food, it may be of service, but as its action upon starch like that of ptyalin is inhibited by the rising acidity of the stomach at mealtime, its range of usefulness as a digestant is certainly not very wide. The third use of the extract of malt is as a vehicle. It is an excellent emulsifying agent and possesses also considerable power in covering unpleasant flavors. For both of these reasons as well as its own nutritive value, it is frequently used in conjunction with cod liver oil. It is also employed widely as a vehicle for cascara sagrada, creosote, and other drugs.

Dose, from one to four fluidrachms (3.75 to 15 cc.).

Off. Prep.—Emulsum Olei Morrhuæ cum Malto, *N. F.*

EXTRACTUM NUCIS VOMICÆ.
U. S. (Br.)

EXTRACT OF NUX VOMICA Ext. Nuc. Vom.
[Powdered Extract of Nux Vomica, Nucis Vomicæ Extractum, P. I.]

"Extract of Nux Vomica yields not less than 15.2 per cent. and not more than 16.8 per cent. of the alkaloids of nux vomica." *U. S.*

"Dry Extract of Nux Vomica contains in 100 grammes 5 grammes of strychnine." *Br.*

Extractum Nucis Vomicæ Siccum, *Br.;* Dry Extract of Nux Vomica; Extractum Nucum Vomicarum Spirituosum (vel Alcoholicum); Extrait de Noix Vomique, *Fr. Cod.;* Extractum Strychni, *P. G.;* Weingeistiges Krähenaugenextrakt, Brechnussextrakt, Strychnossamenextrakt, *G.;* Estratto di noce vomica alcoolico, *It.;* Extracto alcoholico de nuez vomica, *Sp.*

"Nux Vomica, in moderately coarse powder, 1000 Gm.; Alcohol; Water; Acetic Acid; Purified Petroleum Benzin; Starch, dried at 100° C., each, a sufficient quantity. Moisten the drug with a sufficient quantity of a mixture of 75 volumes of alcohol, 1 volume of acetic acid, and 24 volumes of water, pack it firmly in a cylindrical percolator, and add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding more of the same menstruum as required until the drug is practically exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable, and concentrate the liquid until the residue measures about 200 cc. Transfer this residue to a flask or separator, add 150 cc. of water and 200 cc. of purified petroleum benzin, and shake the mixture thoroughly for several minutes. Allow the liquids to separate, and decant the benzin layer as closely as possible, again add to the residue 100 cc. of purified petroleum benzin, agitate, and decant the benzin as before, and then reject the benzin solutions. Evaporate the fat-free residue to dryness on a water bath with frequent stirring. Assay a portion of this product as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the product, and add sufficient of the dried starch to make the finished Extract contain 16 per cent. of the alkaloids of nux vomica. Reduce the mixture to a fine powder, mix thoroughly, pass the extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly." *U. S.*

"Liquid Extract of Nux Vomica, Calcium Phosphate, of each, *a sufficient quantity.* Evaporate ten millilitres of the Liquid Extract in a flat-bottomed dish and dry at 100° C. The weight of the dry extract thus obtained deducted from three grammes gives the weight of Calcium Phosphate to be added to each ten millilitres of the Liquid Extract. Take one hundred parts by volume of the Liquid Extract; recover the alcohol by distillation; add sufficient of the Calcium Phosphate, as indicated by the above determination, to produce, when dried at 100° C., and reduced to a fine powder, thirty parts by weight of the Dry Extract." *Br.*

Assay.—"Proceed by Type Process D, taking 1 Gm. of Extract of Nux Vomica, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.0364 Gm. of the alkaloids of nux vomica (Proximate Assays)." *U. S.*

"3 grammes of Dry Extract of Nux Vomica, when exhausted with *alcohol* (70 per cent.), afford a liquid which when tested by the process described under 'Extractum Nucis Vomicæ Liquidum' yield 0.15 gramme of strychnine, representing in 100 grammes of the Dry Extract 5 grammes of strychnine. *Limit of error* 0.2 gramme in excess or defect. This Dry Extract contains 5 per cent. of strychnine." *Br.*

Extract of Nux Vomica, U. S. P., is a powdered extract containing 16 per cent. of total alkaloids. This alkaloidal strength is the standard adopted by The Brussels Protocol. The U. S. P. VIII standard was 5 per cent. of strychnine and the British Pharm. (1914) retained its former standard of 5 per cent. of strychnine and directed the evaporation of the standardized liquid extract of nux vomica.

The U. S. IX used sulphuric, instead of acetic, acid in this extract. Acetic acid is the most effective menstruum for nux vomica, but has the disadvantage of also extracting inert constituents; it leaves the fixed oil in the marc and this is a great point in its favor.

Dose, one-fourth to one-half of a grain (0.016–0.032 Gm.).

Off. Prep.—Pilulæ Aloes et Podophylli Compositæ, *N. F.;* Pilulæ Ferri, Quininæ Aloes et Nucis Vomicæ, *N. F.;* Pilulæ Laxativæ Post Partum, *N. F.*

EXTRACTUM OPII SICCUM. Br.

DRY EXTRACT OF OPIUM [Opii Extractum, P. I.]

"Dry Extract of Opium contains in 100 grammes 20 grammes of morphine, calculated as anhydrous." *Br.*

Extractum Opii, *U. S. IX.;* Extract of Opium; Extractum Thebaicum; Extrait d'Opium, *Fr. Cod.;* Extrait Thébaique, *Fr.;* Extractum Opii, *P. G.;* Opiumextrakt, *G.;* Estratto di opio acquoso, *It.;* Extracto acuoso de opio, *Sp.*

"Exhaust sliced Opium with about five times its weight of Distilled Water; strain the liquid through flannel; cool and ascertain its volume. Determine the percentage of morphine present in forty millilitres of this liquid by the process described under 'Tinctura Opii,' and determine also the percentage of total solids dried at 100° C. Add to the remainder of the liquid sufficient Calcium Phosphate to yield an extract which, when dried at 100° C., contains 20 per cent. of morphine; evaporate to dryness, powder, and finally dry at 100° C. Examined by the process described under 'Opium,' Dry Extract of Opium is found to contain in 100 grammes 20 grammes of morphine, calculated as anhydrous. *Limit of error* 1 gramme in excess or defect. This Dry Extract contains 20 per cent. of morphine." *Br.*

This extract has been omitted from the U. S. X, but a similar preparation is recognized by the N. F. (see Part III).

As purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, which are capable of causing nausea, headache, nervous disturbances, etc., and which are insoluble in water, though extracted by alcohol or ether. (See *Opium Deodoratum.*)

Dose, one-sixth to one grain (0.01–0.06 Gm.).

Off. Prep.—Extractum Opii Liquidum, *Br.*

EXTRACTUM RHEI. U. S., Br.

EXTRACT OF RHUBARB Ext. Rhei. [Powdered Extract of Rhubarb]

"One Gm. of the Extract represents 2 Gm. of rhubarb." *U. S.*

Extractum Rhei Alcoholicum; Extrait de Rhubarbe, *Fr. Cod.;* Extractum Rhei, *P. G.;* Rhabarberextrakt, *G.;* Estratto di rabarbaro acquoso, *It.;* Extracto acuoso de ruibarbo, *Sp.*

"Rhubarb, in moderately coarse powder, 1000 Gm.; Starch, dried at 100° C.; Alcohol; Water; each, a sufficient quantity to make 500 Gm. Moisten the drug with sufficient of a mixture of 4 volumes of alcohol and 1 volume of water, pack it in a cylindrical percolator, and add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same proportion of alcohol and water as before until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable, and continue distillation until a residue of syrupy consistence remains in the still. Transfer this to a shallow dish, rinse the still with small portions of warm menstruum, add the rinsings to the residue in the dish, and evaporate the mixture to dryness, with frequent stirring, at a temperature not exceeding 70° C. Weigh the dry product, and add sufficient of the dried starch to make the weight 500 Gm. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly." *U. S.*

"Exhaust Rhubarb, in No. 20 powder, with Alcohol (60 per cent.) by the *percolation process.* Recover most of the alcohol from the percolate by distillation, and evaporate the residual liquid to dryness." *Br.*

The British extract (1914) is now nearly identical with the U. S. preparation—except that the U. S. is made to bear a definite relation to the whole drug by adding magnesium oxide—the menstruum used for the former is, however, slightly more aqueous. Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation be performed with great care and with a moderate heat, it is certain that the purgative principle is to a greater or less extent injured or dissipated in the process, and the extract may thus become even less efficient than the root. When properly prepared, the extract has decidedly the peculiar odor of rhubarb.

Dose, from two to ten grains (0.13–0.65 Gm.).

EXTRACTUM STRAMONII. U. S.

EXTRACT OF STRAMONIUM Ext. Stramon.

"Extract of Stramonium yields not less than 0.9 per cent. nor more than 1.1 per cent. of the alkaloids of Stramonium. One gramme of the Extract represents about *four grammes* of stramonium." *U. S.*

Extrait de Stramoine (feuille), *Fr. Cod.;* Stechapfelblätterextrakt, *G.*

"*Pilular Extract of Stramonium.*—Stramonium, in moderately coarse powder, 1000 Gm.; Glucose, Alcohol, Water, each, a sufficient quantity. Moisten the drug with sufficient of a mixture of 3 volumes of alcohol and 1 volume of water, and pack it in a cylindrical percolator; then add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue with frequent stirring at a temperature not exceeding 70° C. to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this Extract as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the mass, and to this add sufficient glucose to make the finished Extract contain 1 per cent of the alkaloids of stramonium. Mix thoroughly.

"**Assay.**—Proceed by Type Process D, taking 2 Gm. of Extract of Stramonium, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of stramonium (Proximate Assays)." *U. S.*

"*Powdered Extract of Stramonium.*—Stramonium, in moderately coarse powder, 1000 Gm.; Starch, dried at 100° C.; Alcohol; each, a sufficient quantity. Moisten the drug with sufficient alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first 1000 cc. of percolate and continue the percolation until the second percolate measures 1000 cc. or until the drug is exhausted. Transfer the second percolate to a suitable apparatus and distil the alcohol at as low a temperature as practicable until a residue measuring about 100 cc. remains, then add the reserved percolate, and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a shallow evaporating dish, rinse the flask or still with small portions of warm alcohol, and add the rinsings to the contents of the dish. Evaporate this to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. Then add 50 Gm. of the dried starch, and continue the heating at the same temperature, with frequent stirring, until the mass is nearly dry. Now thoroughly incorporate an additional 20 Gm. of dried starch, and set the product aside in a current of warm air until thoroughly dry. Reduce the product to a fine powder, and weigh it. Assay a portion of this product as directed below, and from the alkaloidal content thus determined ascertain by calculation the amount of alkaloids in the remainder of the powder, and add to this sufficient of the dried starch to make the finished Extract contain 1 per cent. of the alkaloids of stramonium. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles, and stopper them tightly.

" **Assay.**—Proceed as directed under *Pilular Extract of Stramonium.*" *U. S.*

E'we and Vanderkleed report specimens of extract of stramonium which contain a green coal tar color to simulate the chlorophyll present in extracts made from high grade leaf. This coloring matter interferes with the alkaloidal assay and must be removed by shaking out with chloroform in the acid solution. (*J. A. P. A.*, 1914, 1683.)

Dose, from one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

Off. Prep.—Unguentum Stramonii (from Pilular Extract), *U. S.*

EXTRACTUM STROPHANTHI. Br.

EXTRACT OF STROPHANTHUS

Extrait de Strophanthus Kombé (Semence), *Fr.;* Strophantusextrakt, *G.*

" Strophanthus Seeds, reduced to No. 30 powder, and dried at 45° C., 25 *grammes;* Ether, Alcohol (90 per cent.), Milk Sugar, in powder, of each, *a sufficient quantity.* Pack the Strophanthus Seeds in a percolator; moisten with the Ether, and macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 50° C. Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until two hundred and fifty *millilitres* of liquid are obtained. Evaporate most of the alcohol; transfer the residual liquid to a tared dish; concentrate until the liquid begins to thicken; then add sufficient of the Milk Sugar to produce fifty *grammes* of Extract, in powder." *Br.*

This preparation of the British Pharmacopœia closely resembles an "abstract" of the U. S. P., 1880; an important detail, in our opinion, has been neglected in not washing the fatty matter extracted by the ether with diluted alcohol to remove active constituents held by the fatty substances, then evaporating the solution and incorporating the residue with the extract.

This extract fills a very decided want of a solid preparation of strophanthus that can be administered in pill and capsule. A grain of it may be considered to represent five minims of the U. S. tincture of strophanthus.

Dose, as given in the British Pharmacopœia, from one-fourth to one grain (0.016–0.065 Gm.).

EXTRACTUM TARAXACI. Br.

EXTRACT OF TARAXACUM Ext. Tarax.

Extract of Dandelion; Extrait de Pissenlit, *Fr.;* Extrait de Dent-de-lion, *Fr. Cod.;* Löwenzahnextrakt, *G.;* Estratto di tarassaco acquoso, *It.*

" Crush Taraxacum Root; press out the juice; allow the starchy matter to subside; decant; heat the liquid to 100° C., and maintain the temperature for ten minutes; strain; evaporate to a soft extract." *Br.*

This extract represents whatever therapeutic value dandelion root may possess, in a relatively concentrated form.

Dose, from five to fifteen grains (0.3–1 Gm.) three times a day.

FARFARA. N. F.

COLTSFOOT [Coltsfoot Leaves, Tussilâgo Leaves]

"Coltsfoot is the dried leaf of *Tussilago Farfara* Linné (Fam. *Compositæ*). Coltsfoot contains not more than 3 per cent. of foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

Folia Farfaræ, *P. G.;* Tussilage, Pas d'âne, *Fr.;* Huflattig, Rosshuf, *G.*

Coltsfoot is a low perennial, woolly herb, indigenous to Europe and growing in scattered wet places from Quebec to Pennsylvania and westward to Minnesota. It possesses a horizontal rhizome from which, early in the spring, arise several leaflets, erect, simple scapes or flower-stems bearing yellow, terminal flower-heads surrounded by an involucre of appressed scale-like bracts of a brownish-pink color. The leaves, which appear after the flowers, are all radical, vary in outline from cordate to ovate-reniform and possess white-tomentose lower surfaces. The flowers have an agreeable odor, which they retain after desiccation. The dried root and leaves are inodorous, but have a bitter, mucilaginous taste. The leaves are gathered in June and July and carefully dried. The commercial supply used in the United States comes from Europe.

Description and Physical Properties.—"*Unground Coltsfoot.*—Petiole long, pubescent; blade very brittle, nearly orbicular or broadly ovate-reniform, from 8 to 15 cm. long and nearly as wide, deeply cordate at the base, angular and dentate with red-brown teeth, palmately 5- to 9-nerved; glabrous above, slightly wrinkled, dark green to brownish green or yellowish green. The younger leaves densely white, floccose beneath, the older nearly or often quite glabrous below. Odor indistinct; taste mucilaginous, faintly herbaceous, bitter.

"*Powdered Coltsfoot.*—Yellowish green; numerous multi-cellular, non-branching hairs, usually curved and twisted together, the lower cells up to 0.040 mm. wide, the terminal cells much elongated, 0.010 to 0.024 mm. in width and at times with spiral bands; broadly elliptical stomata up to 0.054 mm. in length and associated with finely striated epidermal cells, the latter having wavy vertical walls; non-porous fibers few with walls from 0.006 to 0.012 mm. in thickness; parenchyma cells containing chloroplastids; tracheæ few, spiral, annular or with simple pores." *N. F.*

C. S. Bondurant (*A. J. P.*, 1887, 340) examined coltsfoot chemically. He found, besides mucilage and tannin, evidences of a bitter glucoside. Klobb isolated two phytosterols from coltsfoot flowers. (*P. J.*, 1909, 999.)

Uses.—The leaves were smoked by the ancients in *pulmonary complaints,* and in Germany they are said to be substituted for tobacco. The only therapeutic value they possess is a demulcent effect due to their mucilage. In the N. F. they are used in a pectoral tea (see *Species Pectorales,* Part III).

Dose, of the dried leaves, one to two drachms (3.9–7.5 Gm.), which may be conveniently given in decoction.

Off. Prep.—Species Pectorales, *N. F.*

FEL BOVIS. U. S.

OXGALL

"Oxgall is the fresh bile of the ox, *Bos taurus* Linné (Fam. *Bovidæ*)." *U. S.*

Fel Bovinum, Fel Tauri, Bilis Bubula, Ox Bile; Bile de Bœuf, *Fr. Cod.;* Ochsengalle, Rindsgalle, *G.;* Hiel de toro, *Sp*

Bile is a viscid fluid varying in color from a golden yellow to a greenish brown. It contains —besides mucin and other proteins, inorganic salts, cholesterin, traces of lecithin and fatty acids—the salts of two peculiar acids known as *glycocholic* and *taurocholic;* the salts of these are sometimes spoken of collectively as the *cholates.* In carnivorous animals the taurocholates predominate but in most herbivors and in man glycocholic salts are the more abundant. *Glycocholic acid,* $C_{26}H_{43}O_6N$, is a white monobasic acid, sparingly soluble in cold water, easily soluble in alcohol, its sodium salt being soluble in either water or alcohol. It is dextro-rotatory. Taurocholic acid, $C_{26}H_{45}SO_7N$, is similar in its general physical properties. The color of bile is due to the presence of two peculiar pigments known as *bilirubin* and *biliverdin* which are apparently derived from the hemoglobin of the blood. Biliverdin can be produced from bilirubin by oxidation. The customary tests for the presence of these bile pigments is to oxidize them, for example with nitric acid, which produces a play of colors passing from red to green, to purple and eventually to yellow (see under *Diagnostic Reagents,* Part II). The bile obtained from the gall-bladder is much more concentrated than that directly secreted by the liver. The commercial oxgall represents largely the bile stored in the gall-bladder.

The following table gives the approximate composition of human bile—in parts per hundred—from the liver and from the gall-bladder.

COMPOSITION OF BILE.

	From the Liver.	From the Gall-bladder.
Total Solids............	1.0 –2.0	10.0–17.0
Sodium Glycocholate ...	0.1 –0.6	6.0–10.0
Sodium Taurocholate ...	0.03–0.06	0.7– 0.9
Fats and Soaps.........	0.1 –0.2	1.0– 3.0
Mucin, etc.	0.2 –0.4	1.4– 3.0
Inorganic Salts..........	0.5 –0.8	0.6– 1.0

The *sodium glycocholate* and *taurocholate* may be separated in the following manner. Dry ox bile is treated with absolute alcohol, and the tincture precipitated by ether in excess. Both salts are deposited, and the glycocholate crystallizes upon standing, the taurocholate remaining in an amorphous form, resembling oily or resinous matter. They may be separated more completely by taking advantage of their different relations to lead acetate and subacetate. Both the acids are precipitated by the subacetate, the glycocholate only by the acetate. If the deposit above referred to be dissolved in water, solution of lead acetate will throw down a lead glycocholate, while the addition of the lead subacetate to the remainder will precipitate the taurocholate. The acids may be separated from the salts of lead by sulphuric acid, and then recombined with soda.

Description and Physical Properties.—"A brownish-green or dark green, somewhat viscid liquid, having a characteristic odor, and a disagreeable, bitter taste.

"Mix two drops of Oxgall with 10 cc. of water and a drop of a freshly prepared solution of 1 part of sucrose in 4 parts of water, and cautiously add sulphuric acid until the precipitate first formed is redissolved. The mixture gradually acquires a brownish-red color, changing successively to carmine, purple, and violet. A frothy mixture is produced when Oxgall is shaken with water.

"Specific gravity: 1.015 to 1.025 at 25° C. Oxgall is neutral or faintly alkaline to litmus paper." *U. S.*

Crude oxgall is rarely used for medical purposes. It is, however, frequently employed for various technical purposes, especially for cleaning cloth. For medicinal properties see *Extractum Fellis Bovis.*

Off. Prep.—Extractum Fellis Bovis, *U. S.;* Fel Bovinum Purificatum, *Br.*

FERRI CARBONAS SACCHARATUS. U. S., Br.

SACCHARATED FERROUS CARBONATE

Ferr. Carb. Sacch.

"Saccharated Ferrous Carbonate contains not less than 15 per cent. of $FeCO_3$." *U. S.* "Saccharated Iron Carbonate is ferrous carbonate, more or less oxidised, mixed with glucose. Contains not less than 50 per cent. of ferrous salts calculated as ferrous carbonate, $FeCO_3$." *Br.*

Saccharated Iron Carbonate; Saccharated Carbonate of Iron; Carbonas Ferrosus Saccharatus; Saccharure de Carbonate Ferreux, *Fr.;* Ferrum Carbonicum Saccharatum, *P. G.;* Zuckerhaltiges Kohlensaures Eisen, Zuckerhaltiges Ferrocarbonat, *G.*

"Ferrous Sulphate, 50 Gm.; Sodium Bicarbonate, 35 Gm.; Lactose, 10 Gm; Sucrose, in fine powder; Diluted Sulphuric Acid; Distilled Water; each, a sufficient quantity to make 100 Gm. Dissolve 8.5 Gm. of sucrose in 200 cc. of hot distilled water, and then dissolve the ferrous sulphate in that solution. Add from 3 to 5 drops of diluted sulphuric acid, and filter. Dissolve the sodium bicarbonate in 500 cc. of distilled water at a temperature not exceeding 50° C., and filter. To the solution of sodium bicarbonate contained in a flask having a capacity of about 1000 cc. gradually add the solution of ferrous sulphate and mix thoroughly by rotating the flask. Fill the flask with boiling distilled water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear supernatant liquid by means of a siphon, fill the flask again with hot distilled water, and shake it. Again draw off the liquid, and repeat the washing with hot distilled water in the same manner until the decanted liquid gives merely a slight cloudiness with barium chloride T.S. Drain the precipitate, transfer it to a porcelain dish containing 61.5 Gm. of sucrose and 10 Gm. of lactose, and mix intimately. Evaporate the mixture to dryness on a water bath, reduce it to a powder, weigh, and mix intimately with it, if necessary, enough well-dried sucrose to make the product weigh 100 Gm. To minimize oxidation make this preparation in the shortest possible time." *U. S.*

"Ferrous Sulphate, 97.5 *grammes;* Glucose, 30.0 *grammes;* Sodium Carbonate, 105.0 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve fifteen *grammes* of the Glucose in three hundred *millilitres* of the Distilled Water, and dissolve the Ferrous Sulphate in the solution. Dissolve the Sodium Carbonate in one hundred and fifty *millilitres* of the Distilled Water, and to this add the solution of the Ferrous Sulphate, stirring constantly. Then add four hundred *millilitres* of the Distilled Water, mix thoroughly, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate with two successive quantities, each of four hundred *millilitres,* of the Distilled Water. Mix the washed precipitate with the remainder of the Glucose, and dry at a temperature not exceeding 100° C. Powder the product, and preserve it in a stoppered bottle." *Br.*

When solutions of ferrous sulphate and sodium carbonate are mixed together, there are formed, by double decomposition, sodium sulphate which remains in solution, and ferrous carbonate which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes ferric oxide, associated with a small quantity of the ferrous carbonate, which has escaped change. As the preparations of ferrous iron are the most esteemed, the change which this precipitate undergoes has always been a matter of regret, and various attempts have been made to prevent it. Saccharine matter has been ascertained to possess the required preservative properties, and in the preparation under consideration it is used to prevent the ferrous carbonate as first precipitated from passing into the ferric hydroxide.

Becker, a German physician, was the first to suggest the use of sugar as a means of protection against the absorption of oxygen, and the idea was carried out by Klauer, a German chemist, who first made the saccharated ferrous carbonate. The use of boiling distilled water in the process is to avoid the action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air, and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying temperature should not exceed 54.5° C.

Description and Physical Properties.—"A greenish-brown, odorless powder, which gradually becomes oxidized by contact with air. Saccharated Ferrous Carbonate is only partially soluble in water.

"When treated with hydrochloric acid, it dissolves with copious evolution of carbon dioxide, a clear greenish-yellow liquid resulting. Dissolve 1 Gm. of Saccharated Ferrous Carbonate in 5 cc. of hydrochloric acid, and dilute the solution with distilled water until it measures 100 cc.: this solution responds to the reactions for ferrous salts.

"A 10 cc. portion of the solution prepared as above, when diluted with distilled water to 50 cc., shows no more *sulphate* than corresponds to 0.5 cc. of fiftieth-normal sulphuric acid.

"Preserve in well stoppered bottles, exposed to light." *U. S.*

"A greenish-brown powder, with a feebly chalybeate taste. Soluble with effervescence in *hydrochloric acid* diluted with half its volume of *water.* 1 gramme, dissolved in excess of warm *concentrated phosphoric acid* and diluted with *water,* does not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 43.1 millilitres of *N/10 solution of potassium bichromate* have been added. *Arsenic limit* 5 parts per million." *Br.*

Assay.—"Dissolve about 2 Gm. of Saccharated Ferrous Carbonate, accurately weighed, in 15 cc. of diluted sulphuric acid, and dilute the solution with distilled water to about 100 cc. Titrate immediately with tenth-normal potassium dichromate, potassium ferricyanide T.S. being used as indicator. Each cc. of tenth-normal potassium dichromate corresponds to 0.01159 Gm. of $FeCO_3$." *U. S.*

Saccharated ferrous carbonate is sometimes seen in small coherent lumps, usually of a grayish-brown color, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in warm hydrochloric acid, diluted with half its volume of water, with effervescence. The presence of ferric oxide is a defect, which is avoided in Vallet's ferruginous mass.

Uses.—The ferrous carbonate has for many years been one of the most highly esteemed chalybeates in the treatment of *chlorosis.* Its great advantage is the complete lack of astringency and consequent acceptability to the stomach. On exposure to the air it absorbs oxygen and is changed to the ferric state, which is apparently a less efficacious remedy. This absorption of oxygen is delayed by the presence of sugar, but the protection is not a complete one. The saccharated ferrous carbonate is inferior to Vallet's mass because in the latter the anti-oxidizing influence of sugar is more fully applied.

Dose, of the saccharated ferrous carbonate, from five to fifteen grains (0.32–1.0 Gm.), given in pills.

FERRI CHLORIDUM. U. S.

FERRIC CHLORIDE Ferr. Chlor. [Iron Perchloride, Sesquichloride of Iron]

" Ferric Chloride contains $FeCl_3$ in a hydrated form, corresponding to not less than 20 per cent. of Fe." *U. S.*

Perchloride of Iron, Chloride of Iron; Ferrum Muriaticum Oxydatum, Chlorum Ferricum; Chloretum Ferricum, Ferri Perchloridum; Chlorure ferrique, Perchlorure de Fer, *Fr.;* Ferrum Sesquichloratum, *P. G.;* Eisenchlorid, *G.;* Cloruro ferrico, *Sp.*

The U. S. P. X does not give a process for preparing ferric chloride; the U. S. P. VIII process is appended.

" Solution of Ferric Chloride, *one hundred grammes,* to make *forty grammes.* Evaporate the Solution of Ferric Chloride on a water-bath until it weighs *forty grammes;* then set it aside in a glass-covered vessel, until it forms a crystalline mass. Lastly, break the salt into pieces, and keep it in glass-stoppered bottles, protected from light." *U. S. VIII.*

For further information concerning the manufacture of this salt, see under *Liquor Ferri Chloridi.*

It contains a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent., or six molecules, when in fine acicular crystals, and only 22 per cent., or two and a half molecules, when in the form of larger tables.

Tasteless Iron Chloride is made by adding an alkaline citrate in solution to a solution of iron sesquichloride, in such proportion that there shall be two molecules of the former and three molecules of chlorine. Usually from 150 to 175 grains of potassium or sodium citrate are required for the preparation of an ounce of a tincture of corresponding strength to the official tincture. The addition should be made to the liquor, and the final solution must not contain more than 40 per cent. of alcohol. R. Rother affirms that these so-called salts are mere mixtures of iron citrate and iodide or chloride of the alkali used. (See *Tinctura Ferri Citro-Chloridi,* N. F., Part III.)

Description and Physical Properties.—" Orange-yellow, or brown-yellow, crystalline pieces. It is odorless, or has a faint odor of hydrochloric acid, and a strongly styptic taste. It is very deliquescent. One Gm. of Ferric Chloride is soluble in 0.2 cc. of water at 25° C. It is freely soluble in alcohol, and is soluble in glycerin and in ether. At about 35.5° C. the salt fuses to a reddish-brown liquid. When strongly heated, it is decomposed, leaving a residue of ferric oxide.

" Ferric Chloride responds to the reactions for ferric iron, and for chlorides. An aqueous solution of Ferric Chloride, made by dissolving 10 Gm. of the salt in 15 cc. of distilled water, complies with the tests for purity under *Liquor Ferri Chloridi,* omitting the test for hydrochloric acid.

" Preserve in well closed glass containers protected from light.

" **Assay.**—Dissolve about 1 Gm. of Ferric Chloride, accurately weighed in a stoppered weighing-bottle, in 25 cc. of distilled water, transfer to a glass-stoppered flask or bottle, add 3 cc. of hydrochloric acid with 4 Gm. of potassium iodide, stopper the container securely, and allow the mixture to stand for thirty minutes at a temperature of 40° C. Cool this solution, then dilute it with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe." *U. S.*

Ferric chloride is incompatible with alkalies and with iodides and bromides from which it liberates the halogen elements; also with tannic acid and most vegetable tinctures.

Uses.—Ferric chloride is used almost exclusively in the form of the tincture or solution, and in reference to its effect and application we refer to *Tinctura Ferri Chloridi* and *Liquor Ferri Chloridi.* Excepting deliquescence, it keeps without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended, the stronger solutions being used in the treatment of *varices,* the weaker for application to *bleeding surfaces,* etc. J. Z. Lawrence, of England, has used it as a styptic in a semi-deliquescent state, and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces, and applies the thick liquid portion, with a brush of spun glass, to the bleeding surface.

Dose, one grain (0.065 Gm.).

FERRI ET AMMONII CITRAS. U. S., Br.

IRON AND AMMONIUM CITRATE Ferr. et Ammon. Cit. [Ammonio-Ferric Citrate, Soluble Ferric Citrate]

"Iron and Ammonium Citrate is ferric citrate rendered more readily soluble by the presence of ammonium citrate and contains not less than 16 per cent. and not more than 18 per cent. of Fe." *U. S.*

Citrate of Iron and Ammonia; Ferri et Ammoniæ Citras, *Br.*, 1867; Ferrum Citricum Ammoniatum, Ferri Ammonio-Citras, Ferro-Ammonium Citricum; Ammonio-Citrate of Iron, Soluble Citrate of Iron; Citras Ferri Ammoniacalis; Ferrum Ammonio-Citricum, *Fr. Cod.;* Citrate de Fer et d'Ammoniaque, Citrate Ferrique Ammoniacal, *Fr.;* Citronensaures Eisenoxyd-Ammonium (Ammoniak), Ferriammoniumcitrat, *G.;* Citrato ferricoammonico, *Sp.*

No process is given in the U. S. P. X for Iron and Ammonium Citrate. The British Pharm., 1914, process is as follows: "Solution of Ferric Sulphate, 200 *millilitres;* Solution of Ammonia, 460 *millilitres,* or *a sufficient quantity;* Citric Acid, 80 *grammes;* Distilled Water, *a sufficient quantity.* Prepare ferric hydroxide as follows:—Mix three hundred and twenty millilitres of the Solution of Ammonia with eight hundred millilitres of Distilled Water; gradually add to this the Solution of Ferric Sulphate, previously diluted with eight hundred millilitres of Distilled Water; stir constantly and briskly, taking care that ammonia is, finally, in slight excess as indicated by the odor; set aside the mixture for two hours, stirring it occasionally; pour it on a calico filter; when the liquid has drained away, wash the precipitated ferric hydroxide with Distilled Water until free from sulphates. Dissolve the Citric Acid in its own weight of Distilled Water; warm the mixture on a water-bath; add the ferric hydroxide, previously well drained; stir them together until nearly the whole of the hydroxide has dissolved, or until the Citric Acid is saturated with ferric hydroxide (prepared, if necessary, from more of the Solution of Ferric Sulphate); let the solution cool; add one hundred and ten millilitres of Solution of Ammonia; filter through flannel, adding some Distilled Water if necessary, evaporate to the consistence of syrup, the presence of a very slight excess of ammonia being maintained; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C.; remove the dry flakes of Iron and Ammonium Citrate." *Br.*

In the U. S. Pharmacopœia, 1890, the process consisted simply in evaporating a mixture of solution of ferric citrate and ammonia water. In the British, ferric hydroxide is first precipitated from a solution of the ferric sulphate, then digested at a moderate heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by E. R. Squibb that a heat above 82.1° C. acts injuriously in the preparation of the ferric citrate, and the present Br. Pharmacopœia directs that the salt should be dried at a heat not above 40° C. In the U. S., 1890, formula the ferric citrate was used already prepared, in the British it is prepared in the process. The solution should be concentrated to a syrupy consistence before being poured out on porcelain or glass to dry, and it is important that the heat employed in the concentration should not exceed that indicated. Like most of the scaled iron salts, this preparation is not a true chemical compound, the ammonia not being in the proportion to form a double salt.

Iron and ammonium citrate has come into use recently for subcutaneous or intramuscular injection. It has been discovered that certain forms of this compound produce much more irritation or pain than others, when thus administered upon investigation it was learned that when less than 8 per cent. of ammonia (in the form of ammonium) is present, severe systemic reactions are likely to occur, while an ammonia content that is much over 8 per cent. is likely to cause severe local irritation.

A form of special *iron and ammonium citrate, green,* has been recognized by the *N. N. R.*, containing ferric citrate equivalent to 16 per cent. of iron (Fe) and ammonium citrate equivalent to 8.1 per cent. of ammonium (NH_3). This product is of U. S. P. quality as regards the iron content, but is specifically standardized as to ammonia content.

Description and Physical Properties.—"Thin, transparent, garnet-red scales or granules. It is odorless, and has a saline, mildly ferruginous taste. It is deliquescent in moist air. Iron and Ammonium Citrate is readily soluble in water. It is insoluble in alcohol.

"When strongly heated, it chars, and finally leaves a residue of ferric oxide. An aqueous solution of Iron and Ammonium Citrate (1 in 20) is neutral or but slightly acid or alkaline to litmus paper. Heat about 0.1 Gm. of Iron and Ammonium Citrate with about 5 cc. of potassium hydroxide T.S.: a brownish-red precipitate is produced and ammonia is evolved. Ammonia T.S. added to an aqueous solution of Iron and Ammonium Citrate (1 in 100) produces no precipitate, but darkens the solution.

"Remove the iron from 10 cc. of an aqueous solution of Iron and Ammonium Citrate (1 in 10) by boiling it with an excess of potassium hydroxide T.S., filter, and then slightly acidulate 4 cc. of the filtrate with acetic acid: a portion of the cooled filtrate, when mixed with 2 cc. of calcium chloride T.S., and again heated to boiling, gradually deposits a white, crystalline precipitate. The remainder of the filtrate, when acidulated more strongly with acetic acid and allowed to stand for twenty-four hours, does not yield a white, crystalline precipitate (*tartrate*). An aqueous solution of Iron and Ammonium Citrate (1 in 100) does not yield a blue precipitate with potassium ferrocyanide T.S. unless it is previously acidulated with hydrochloric acid (*ferric citrate*).

"Preserve in well-closed containers, protected from light." *U. S.*

"In thin, dark red, transparent scales. Taste slightly sweet and astringent. Soluble in 0.5 part of *water;* almost insoluble in *alcohol* (90 per cent.). Aqueous solution slightly acid to *litmus.* Yields from 31 to 32 per cent. of ash, which, when moistened with *water,* is not alkaline to *litmus* (absence of fixed alkali). When a solution of 1 gramme in 10 millilitres of *water* is heated with a slight excess of *solution of potassium hydroxide,* ammonia is evolved and ferric hydroxide is precipitated; the filtrate from this, acidified with *acetic acid,* does not yield any crystalline precipitate (absence of tartrates). Yields not more than the slightest characteristic *reaction* for sulphates. *Arsenic limit* 5 parts per million." *Br.*

"**Assay.**—Dissolve about 1 Gm. of Iron and Ammonium Citrate, accurately weighed, in 25 cc. of distilled water and 7 cc. of hydrochloric acid, in a glass-stoppered flask or bottle, add 4 Gm. of potassium iodide, stopper the container securely, and keep it at a temperature of 40° C. for thirty minutes. Then cool, dilute with 100 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe." *U. S.*

Uses.—This salt is a pleasant chalybeate, being practically free from astringency or local irritant action. It should be prescribed only in solution, as it is not suited for administration in the form of pills, owing to the presence of ammonia, which renders it too soluble, and causes the pills to flatten after they have been made, and frequently to cohere in one solid mass. The plain ferric citrate should always be used for pills, as it is less hygroscopic and makes more stable pills.

Dose, from three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Vinum Ferri Citratis, *Br.;* Elixir Carnis et Ferri, *N. F.*

FERRI ET POTASSII TARTRAS. Br.

IRON AND POTASSIUM TARTRATE

Ferrum Tartaratum; Tartarated Iron; Potassio-ferric Tartrate; Ferri Potassio-Tartras, Ferrum Tartarizatum, Tartras Ferrico-Potassicus, s. Potassico-Ferricus, s. Ferrico-Kalicus, Ferri-Kalium Tartaricum; Tartarated (tartarized) Iron, Ferro-Tartrate of Potassium; Tartrate Ferrico-potassique, Tartrate de Fer et de Potasse, Tartre martial, *Fr.;* Ferritartrate de Potassium, *Fr. Cod.;* Kaliumferritartrat, Weinsäures Eisenoxyd-Kali, Eisenweinstein, *G.;* Tartrato ferrico-potassico, *It.;* Tartrato ferrico-potasico, *Sp.*

The U. S. no longer recognizes this salt, which represents about 15 per cent. of iron.

The British process is as follows: "Solution of Ferric Sulphate, 200.0 *millilitres;* Solution of Ammonia, 320.0 *millilitres,* or *a sufficient quantity;* Acid Potassium Tartrate in powder, 66.5 *grammes;* Distilled Water, *a sufficient quantity.* From the Solution of Ferric Sulphate prepare ferric hydroxide as directed under 'Ferri et Ammonii Citras.' Mix the ferric hydroxide intimately with the Acid Potassium Tartrate in a porcelain dish; let the mixture stand for twenty-four hours; heat to a temperature not exceeding 60° C., add gradually six hundred *millilitres* of Distilled Water; stir constantly until nothing more will dissolve; filter; evaporate at a temperature not exceeding 60° C. to the consistence of syrup; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C.; remove the dry flakes of Iron and Potassium Tartrate." *Br.*

The object of this process was to combine the excess of acid in the potassium bitartrate with ferric hydroxide. The plan of Soubeiran in the main was adopted—namely, that of dissolving the moist ferric hydroxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The oxide is obtained from the solution of ferric sulphate, which is precipitated by ammonia. Potassium hydroxide, which was used in the former British process, is not a good precipitant, because the alkali adheres obstinately to the precipitated oxide, and cannot be completely separated even by repeated washings. The oxide should be gradually added to the bitartrate and water, heated to 60° C., at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the ferric oxide is converted into ferrous oxide. W. Lyon (*P. J.,* 1902, 530) proposes to substitute potassium and sodium tartrate for the acid potassium tartrate used in the British Pharm. process, believing that the resulting scaled salt will retain its ready solubility for a much longer time than will the official preparation; he uses the following proportions: Solution of ferric sulphate 300 cc.; solution of ammonia 480 cc. or a sufficient quantity; potassium and sodium tartrate 176 Gm. The official process and directions are otherwise followed. For Roger's process for this salt and the manufacture of *Boules de Mars* (balls of iron and potassium tartrate), see *U. S. D.,* 17th ed., 611.

Ure proposed *ferrous tartrate* for medicinal use. He made it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties.—Iron and potassium tartrate is in "thin, transparent scales of a deep garnet color; taste somewhat sweetish and astringent. Soluble in *water,* sparingly soluble in *alcohol* (90 per cent.). *Arsenic limit* 5 parts per million. The aqueous solution, acidified with *hydrochloric acid,* yields a copious blue precipitate with *solution of potassium ferrocyanide.* When a solution of 1 gramme in 10 millilitres of *water* is boiled with a slight excess of *solution of potassium hydroxide,* a reddish-brown precipitate separates, and the filtered solution, slightly acidified with *acetic acid,* yields, as it cools, a crystalline deposit. Yields not less than 30 per cent. of ferric oxide when incinerated with free access of air, the ash being washed with *water* and again incinerated." *Br.*

According to the view of its nature taken in the U. S. Pharmacopœia VIII, it is a double salt, consisting of one molecule of ferric tartrate and one of potassium tartrate:

$$Fe_2(C_4H_4O_6)_3 + K_2C_4H_4O_6 + H_2O$$

Flückiger (*Pharmaceutische Chemie,* 2d ed., 573, 188), on the other hand, considers the salt formed to be one in which Fe_2O_2 is present as a bivalent group, and gives it the formula:

$$C_4H_4O_6K_2 + C_4H_4O_6(Fe_2O_2) + 4H_2O$$

The salt is incompatible with astringent vegetable infusions, which give rise to a dark-colored precipitate.

Uses.—Iron and potassium tartrate is a mild, agreeable chalybeate, with but little astringency. It is well borne by the stomach, taken fasting or with the food. Its slight taste and ready solubility make it one of the best ferruginous preparations for children.

Dose, for an adult, five to ten grains (0.32–0.65 Gm.), given preferably in solution.

FERRI ET QUININÆ CITRAS. Br.

IRON AND QUININE CITRATE

Ferri et Quininæ Citras, Solubilis, *U. S. VIII;* Soluble Iron and Quinine Citrate; Citrate of Iron and Quinia; Citras Ferricus cum Chinina; Citrate de Fer et de Quinine, *Fr.;* Chininum Ferro-Citricum, *P. G.;* Eisenchinincitrat, Citronensaures Eisen-Chinin, *G.*

This mixture has been very properly omitted from the U. S. X.

"Solution of Ferric Sulphate, 180 *millilitres;* Quinine Sulphate, 40 *grammes;* Diluted Sulphuric Acid, 60 *millilitres;* Citric Acid, 123 *grammes;* Solution of Ammonia, Distilled Water, of each, *a sufficient quantity.* From the Solution of Ferric Sulphate prepare ferric hydroxide as directed under 'Ferri et Ammonii Citras.' Mix the Quinine Sulphate with eight times its weight of Distilled Water; add the Diluted Sulphuric Acid; when the salt is dissolved precipitate the quinine with a slight excess of Solution of Ammonia; collect the precipitate on a filter; wash it with twelve hundred *millilitres* of Distilled Water. Dissolve the Citric Acid in its own weight of Distilled Water; warm the solution on a water-bath; add the ferric hydroxide, previously well drained; stir them together; when the hydroxide has dissolved, add the precipitated quinine; continue the stirring until this also has dissolved; let the solution cool; add, in small quantities at a time, sixty *millilitres* of Solution of Ammonia, diluted with eighty *millilitres* of Distilled Water; stir briskly, allowing the quinine which separates with each addition of ammonia to dissolve before the next addition is made; filter the solution; evaporate it to the consistence of a thin syrup; dry the latter in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C.; remove the dry flakes of Iron and Quinine Citrate." *Br.*

The final addition of ammonia is in order to render the iron and quinine citrate more soluble by the agency of a portion of ammonium citrate. It is important that the ammonia should not be added in excess; on the contrary, the solution should retain a slight acid reaction. After evaporation, the salt is dried, as in the other process, on glass or porcelain, so as to be obtained in thin scales.

No analysis has been made that determines precisely the chemical composition of this "scaled salt." It is undoubtedly a mere mixture of the iron and quinine citrates, containing ammonium citrate.

According to C. H. Wood (*P. J.,* 2d ser., x, 644), this salt undergoes a rapid change of composition when exposed to the influence of the direct rays of the sun.

Properties.—The British Pharm., 1914, describes it as "in thin scales of a greenish-yellow color, somewhat deliquescent; taste bitter, chalybeate. Soluble in 0.5 part of *water.* The solution is very slightly acid, and yields precipitates which are reddish-brown with *solution of potassium hydroxide,* white with *solution of ammonia,* blue with *solution of potassium ferrocyanide,* and with *solution of potassium ferricyanide. Arsenic limit* 5 parts per million. Ash, when moistened with *water,* not alkaline to *litmus* (absence of fixed alkali). 5 grammes, dissolved in 45 millilitres of *water* and treated with excess of *solution of ammonia,* yield a white precipitate, which, when dissolved out by repeated treatment of the liquid with chloroform, the latter evaporated, and the residue dried at 110° C., weighs not less than 0.75 gramme. This precipitate is almost entirely soluble in a little *ether;* on incineration it leaves not more than a minute residue; neutralised with *diluted sulphuric acid* and crystallised, it possesses the characters of and responds to the tests described under 'Quininæ Sulphas.'" *Br.*

See modification of process by F. A. Sieker (*Ph. Rund.,* 1895, 36).

The U. S. IX gave the following methods for determining the amount of quinine and iron respectively.

"**Assay for Quinine.**—Dissolve about 1 Gm. of Iron and Quinine Citrate, accurately weighed, in 20 mils of distilled water in a separator, add 5 mils of ammonia water and 10 mils of chloroform, and shake the separator for one minute. Allow the liquids to separate, draw off the chloroform layer through a small filter moistened with chloroform, into a tared dish, and shake the residuary liquid a second and a third time with portions of 10 mils each of chloroform, passing the chloroform through the filter each time and finally washing the filter with 5 mils of chloroform. Evaporate the combined chloroform solutions, redissolve the residue in 3 mils of alcohol, again evaporate and then dry the residue to constant weight at 100° C. This residue corresponds to not less than 11.5 per cent. of the amount of Iron and Quinine Citrate taken for the assay and conforms to the identity tests under *Quinina*." *U. S. IX.*

The quinine in this assay is undoubtedly contaminated with traces of the strychnine present. There is no reliable method for the separate determination of the two alkaloids in this compound.

"**Assay for Iron.**—Heat the aqueous liquid from which the quinine has been removed in the manner just described, on a water bath, until the odors of chloroform and of ammonia have disappeared, allow to cool and dilute with distilled water to a volume of 25 mils. Transfer the liquid to a glass-stoppered bottle, add 15 mils of hydrochloric acid and 3 Gm. of potassium iodide, and, after securely closing the bottle, allow the mixture to stand for thirty minutes at 40° C. Then cool and titrate with sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 13 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Iron and Quinine Citrate corresponds to not less than 23.3 mils of tenth-normal sodium thiosulphate V.S." *U. S. IX.*

Uses.—Preparations of this character are therapeutically irrational; if the hematinic effects of iron and the tonic action of quinine are desired simultaneously, it is far better to compose an extemporaneous mixture in which the proportion of each shall be regulated to the needs of the individual patient than resort to a fixed combination. Each five grains (0.3 Gm.) of the salt represents approximately one-half grain (0.032 Gm.) of quinine and two-thirds of a grain (0.036 Gm.) of iron.

Dose, five to ten grains (0.32–0.65 Gm.).

FERRI GLYCEROPHOSPHAS. N. F.

FERRIC GLYCEROPHOSPHATE Ferr. Glycerophos. [Ferric Glycerinophosphate]

"Ferric Glycerophosphate contains a variable quantity of $Fe_2(C_3H_7O_6P)_3$(622.02) corresponding to not less than 14 per cent. and not more than 16 per cent. of Fe." *N. F.*

Ferrum Glycerinophosphoricum; Iron Glycerophosphate; Glycerinphosphorsaures Eisen, *G.*

Description and Physical Properties.—"Ferric Glycerophosphate occurs as yellowish green, transparent, amorphous scales or as a greenish yellow powder; odorless and nearly tasteless. One Gm. dissolves slowly in about 2 cc. of water at 25° C.; insoluble in alcohol. An aqueous solution is acid to litmus and becomes turbid when heated.

An aqueous solution of the salt (1 in 20) is colored dark blue by potassium ferrocyanide T.S.; on the subsequent addition of hydrochloric acid a dark blue precipitate is produced. Heat a powdered mixture of about 0.1 Gm. of the salt with about 0.5 Gm. of potassium bisulphate; the pungent vapors of acrolein are evolved.

"Not more than a slight yellow turbidity is produced at once on mixing 5 cc. of an aqueous solution of the salt (1 in 50) with 10 cc. of ammonium molybdate T.S. (*phosphate*), but on standing or on warming, a yellow precipitate is formed. An aqueous solution of the salt (1 in 50), acidulated with hydrochloric acid, does not become more than slightly turbid on the addition of barium chloride T.S. (*sulphate*). Another portion of this aqueous solution, acidulated with nitric acid, does not become more than slightly turbid on the addition of silver nitrate T.S. (*chloride*).

"**Assay.**—Dissolve about 0.5 Gm. of Ferric Glycerophosphate, accurately weighed, in 50 cc. of distilled water, in a 100 cc. glass-stoppered flask, add 5 cc. of hydrochloric acid and about 3 Gm. of potassium iodide. Warm to 40° C., and allow the mixture to stand one-half hour at this temperature in the stoppered flask, cool, and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe. Each gram of Ferric Glycerophosphate corresponds to not less than 25.07 cc. nor more than 28.65 cc. of tenth-normal sodium thiosulphate.

"Preserve it in well-closed containers, protected from light." *N. F.*

This is made by dissolving freshly precipitated ferric hydroxide in glycerophosphoric acid, evaporating the solution *in vacuo* and scaling it upon glass plates.

The salt is used as a tonic and nervine in *doses* of from five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Elixir Glycerophosphatum Compositum, *N. F.*

FERRI HYPOPHOSPHIS. N. F.

FERRIC HYPOPHOSPHITE Ferr. Hypophos.

"Ferric Hypophosphite contains not less than 98 per cent. of $Fe(PH_2O_2)_3$(251.01), corresponding to not less than 21.8 per cent. of Fe." *N. F.*

Ferric Hypophosphite, *N. F. IV;* Iron Hypophosphite; Hypophosphite of Iron; Ferrum Hypophosphorosum; Hypophosphis Ferricus; Hypophosphite de Fer, *Fr.;* Unterphosphorigsaures Eisenoxyd, Ferrihypophosphit, *G.*

This salt may be made by the action of hypophosphorous acid on ferrous carbonate formed by precipitation from the sulphate.

Description and Physical Properties.—"Ferric Hypophosphite occurs as a white, or grayish white powder, odorless and nearly tasteless; permanent in the air. One Gm. dissolves in 2300 cc. of water at 25° C. and in 1200 cc. of boiling water; more readily soluble in the presence of hypophosphorous acid or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution.

"When strongly heated in a dry test tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and finally leaves a residue of ferric pyrophosphate. Ferric Hypophosphite is readily oxidized by nitric acid or other oxidizing agents.

"Add 15 cc. of acetic acid to 1 Gm. of the salt; no effervescence occurs (*carbonate*). Heat the mixture to boiling and filter; the filtrate responds to the following tests. Add to a portion of the filtrate a few drops of silver nitrate T.S. and warm; a brown to black coloration or precipitate is produced. To another portion of the filtrate add, drop by drop, an excess of mercuric chloride T.S.; a white precipitate of mercurous chloride is formed upon gently heating. Another 5 cc. portion of the filtrate shows no turbidity with ammonium oxalate T.S. within one minute (*calcium*). Dissolve 1 Gm. of the salt in 20 cc. of diluted hydrochloric acid, with the aid of heat, and add 1 cc. of barium chloride T.S.; not more than a slight turbidity is produced (*sulphate*). Boil 0.5 Gm. of the salt with 10 cc. of sodium hydroxide T.S.; a reddish brown precipitate is produced. Filter this mixture, slightly acidulate the filtrate with hydrochloric acid, add magnesia mixture T.S. and then an excess of ammonia water; no crystalline precipitate is produced (*phosphate*). Dissolve 1 Gm. of the salt in about 25 cc. of boiling distilled water by the aid of sufficient hydrochloric acid, added drop by drop, then add 2 cc. of nitric acid, boil and add a slight excess of ammonia water; the filtrate is colorless, and after acidulating with hydrochloric acid does not respond to the Test for heavy metals.

"**Assay.**—To 1 Gm. of Ferric Hypophosphite accurately weighed, add 10 cc. of nitrohydrochloric acid and evaporate to dryness on a water-bath. Dissolve the residue in 25 cc. of distilled water and 10 cc. of hydrochloric acid, transfer the solution to a glass-stoppered flask, add 3 Gm. of potassium iodide, keep it at 40° C. for thirty minutes, cool and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe, and 0.025101 Gm. of $Fe(PH_2O_2)_3$. Each gram of Ferric Hypophosphite requires not less than 39.04 cc. of tenth-normal sodium thiosulphate.

"Preserve it in well-closed containers." *N. F.*

Syrup of ferrous hypophosphite may be prepared by simply adding syrup to the solution of the hypophosphite.

Ferric hypophosphite is a feeble chalybeate, but has no advantages over the other official salts of iron. It enters into that therapeutic hodge-podge, the *Compound Syrup of Hypophosphites*. It may be administered in the form of pill or powder, but the syrup is more elegant.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Syrupus Hypophosphitus Compositus, *N. F.;* Liquor Hypophosphitum Compositum, *N. F.*

FERRI HYDROXIDUM CUM MAGNESII OXIDO. U. S.

FERRIC HYDROXIDE WITH MAGNESIUM OXIDE

Ferr. Hydrox. cum Mag. Oxid. [Arsenic Antidote, Ferric Hydrate with Magnesia]

Ferri Oxidum Hydratum cum Magnesia, *U. S.* 1890; Antidotum Arsenici; Antidote to Arsenious Acid; Hydrated Oxide of Iron with Magnesia; Contre-poison de l'arsenic, *Fr.;* Gegengift des Arseniks, Gegengift der Arsenigensaure, *G.;* Hidrato ferrico magnesico, *Sp.*

"Solution of Ferric Sulphate, 40 cc.; Magnesium Oxide, 10 Gm.; Water, a sufficient quantity. Mix the solution of ferric sulphate with 125 cc. of water, and keep the liquid in a large, well-stoppered bottle. Rub the magnesium oxide with cold water to a smooth, thin mixture, transfer this to a bottle capable of holding about 1000 cc., fill it with water to about three-fourths of its capacity, and keep it tightly stoppered. When the preparation is needed, shake the magnesium oxide mixture until of a thin, creamy consistence, slowly add to it the diluted solution of ferric sulphate, and shake them together until a uniformly smooth mixture results. Note—In this process the 10 Gm. of magnesium oxide may be replaced by 300 cc. of magnesia magma, diluting it with sufficient water to make the required volume.

"The diluted solution of ferric sulphate and the magnesia mixture should be kept on hand in separate bottles ready for immediate use so that the antidote may be quickly prepared." *U. S.*

Ferric hydroxide was dropped from the U. S. P. IX and ferric hydroxide with magnesium oxide retained. This is a preparation which has been introduced for the purpose of furnishing a ready and efficient antidote against arsenic trioxide or arsenous acid. It is almost identical with the *Antidotum Arsenici* of the German Pharmacopœia. Ferric hydroxide is produced when to the mixture of magnesia is added the diluted solution of ferric sulphate, and, as the magnesia is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. When mixed as officially directed, and ready for use, it contains ferric hydroxide with magnesium sulphate and hydroxide.

Uses.—The sesquioxide of iron was brought forward as an antidote in arsenical poisoning by Bunsen and Berthold in 1834. According to Wormley its antidotal effect is due to the ferric oxide yielding oxygen and thereby converting the arsenious acid into the arsenic state, the latter then uniting with the iron to form an insoluble arsenate. In the early part of the last century there waged a vigorous discussion as to the comparative usefulness of this antidote, as the result of which for more than half a century it became recognized as the standard antidote for arsenic. This position it held for more than half a century almost undisputed. Its efficacy, however, was attacked by Busscher in 1902. McGuigan reinvestigated the question (*J. A. Ph. A.*, 1923, xii, 327) and reached the conclusion that what little antidotal effect it exerted was purely physical. As pointed out, however, by H. C. Wood (*J. A. Ph. A.*, xii, 482) their experimental evidence scarcely justifies so sweeping a condemnation of a widely used remedy. (See *Arseni Trioxidum.*)

Dose, four fluidounces (120 cc.).

FERRI LACTAS. N. F.

FERROUS LACTATE Ferr. Lact. [Iron Lactate]

"Ferrous Lactate contains not less than 97 per cent of $Fe(C_3H_5O_3)_2.3H_2O$ (288.00)." *N. F.*

Iron Lactate; Ferrum Lacticum, *P. G.;* Lactas Ferrosus, Lactate de Fer, *Fr.;* Milchsaures Eisenoxydul, Eisenlactat, *G.;* Lactato Ferroso, *Sp.*

The U. S. P. V gave a process for preparing ferrous lactate through the direct action of lactic acid on iron wire.

It may be more cheaply prepared, on the large scale, by digesting the impure acid, with iron filings, or by reaction between ferrous sulphate and the calcium lactate prepared as a step in obtaining lactic acid.

Description and Physical Properties.—"Ferrous Lactate occurs as a greenish white crystalline powder, or in crystalline masses, having a slight, characteristic odor, and a mild, sweet and ferruginous taste. One Gm. dissolves slowly but almost completely in 40 cc. of water at 25° C., and in 12 cc. of boiling water; freely soluble in solutions of the alkali citrates yielding a green-colored solution; almost insoluble in alcohol.

"When strongly heated, the salt froths, gives out dense, white, acrid fumes, then chars and finally leaves a brownish red residue. An aqueous solution of the salt is greenish yellow, slightly acid to litmus, and separate portions give a deep blue precipitate with potassium ferricyanide T.S., and a light blue precipitate with potassium ferrocyanide T.S.

"Separate portions of an aqueous solution of the salt (1 in 20), acidulated with nitric acid, do not give more than a slight opalescence with barium chloride T.S. (*sulphate*), or with silver nitrate T.S. (*chloride*). Mix 25 cc. of an aqueous solution of the salt (1 in 50) with 5 cc. of diluted sulphuric acid, boil the mixture for a few minutes, then precipitate the iron by an excess of sodium hydroxide T.S., and filter; the filtrate, mixed with a few drops of alkaline cupric tartrate solution and heated to boiling, does not give a red precipitate (*sugar*). A portion of the salt triturated with sulphuric acid does not develop an offensive odor (*butyric acid*); this mixture, after standing for five minutes, does not assume more than a pale brown color (*readily carbonizable impurities*). Ignite 1 Gm. of the salt and triturate the residue with 10 cc. of distilled water, the liquid is not alkaline to moistened litmus paper. Filter, wash the filter with about 10 cc. of distilled water, evaporate the filtrate and washings to dryness, and ignite gently; the weight of the residue does not exceed 0.003 Gm.

"**Assay.**—Dissolve, in a glass-stoppered flask, about 0.5 Gm. of Ferrous Lactate, accurately weighed, in 15 cc. of solution of hydrogen dioxide and 5 cc. of hydrochloric acid, and evaporate this solution on a water-bath to 5 cc. Add 3 cc. of hydrochloric acid, boil the mixture for two minutes, cool to 40° C. and add 25 cc. of distilled water and 1 Gm. of potassium iodide. Allow this mixture to stand for one-half hour at 40° C., cool, and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.0288 Gm. of $Fe(C_3H_5O_3)_2 + 3H_2O$. Each gram of Ferrous Lactate requires not less than 33.7 cc. of tenth-normal sodium thiosulphate.

"Preserve it in well-closed containers." *N. F.*

Ferrous lactate has the general medicinal properties of the ferruginous preparations, and has been especially used in *chlorosis.* As much as twelve or even twenty grains (0.78–1.3 Gm.) may be given in the course of a day. It may be administered in pill, or syrup; the *pill,* of one grain (0.065 Gm.) of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey.

Dose, three to six grains (0.2–0.4 Gm.).

Off. Prep.—Syrupus Calcii Lactophosphatis et Ferri, *N. F.*

FERRI PHOSPHAS SOLUBILIS. U. S.

SOLUBLE FERRIC PHOSPHATE Ferr. Phos. Sol. [Ferri Phosphas, U. S. P. IX, Ferric Phosphate with Sodium Citrate]

"Soluble Ferric Phosphate is ferric phosphate rendered soluble by the presence of sodium citrate and contains not less than 12 per cent. of Fe." *U. S.*

Ferri et Sodii Citro-phosphas; Ferrum Phosphoricum cum Natrio Citrico; Soluble Phosphate of Iron, Sodio-ferric Citrophosphate; Citro-phosphate de Fer et de Soude, *Fr.;* Natriumeisencitro-phosphat, *G.*

The word "solubilis" has been reinserted in the title of the U. S. P. X, in order to distinguish this preparation from the normal ferric phosphate. The latter which was at one time official is an insoluble yellowish powder. The present is in thin bright green scales.

No process is given for this preparation in the U. S. P. X. That of the U. S. P., 1890, is as follows: "Ferric Citrate, *fifty grammes;* Sodium Phosphate, uneffloresced, *fifty-five grammes;* Distilled Water, *one hundred cubic centimeters.* Dissolve the ferric Citrate in the Distilled Water by heating on a water-bath. To this solution add the Sodium Phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C., to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.*, 1890.

Description and Physical Properties.—"Thin, bright green, transparent scales or granules. It is without odor, and has an acidulous, slightly saline taste. The salt is stable in dry air when protected from light, but when unprotected soon becomes discolored. Soluble Ferric Phosphate is freely soluble in water. It is insoluble in alcohol.

"An aqueous solution of Soluble Ferric Phosphate (1 in 10) is slightly acid to litmus paper. The addition of an excess of ammonia T.S. to an aqueous solution of Soluble Ferric Phosphate produces a reddish-brown color but no precipitate. Boil about 0.1 Gm. of Soluble Ferric Phosphate with 5 cc. of sodium hydroxide T.S.: a brownish-red precipitate is produced without the evolution of ammonia (*ammonium salts*). Remove the iron from 10 cc. of an aqueous solution of Soluble Ferric Phosphate (1 in 10) by boiling it with an excess of sodium hydroxide T.S., filter out the precipitate, and strongly acidulate the filtrate with hydrochloric acid: a cooled portion of this liquid mixed with an equal volume of magnesia mixture T.S. and treated with a slight excess of ammonia T.S. produces an abundant white, crystalline precipitate. This precipitate, after washing, turns yellow when treated with a few drops of silver nitrate T.S. (*distinction from pyrophosphate*).

"Preserve in amber-colored, well-stoppered bottles, protected from light.

"**Assay.**—Dissolve about 1 Gm. of Soluble Ferric Phosphate, accurately weighed, in 25 cc. of distilled water and 15 cc. of hydrochloric acid, in a glass-stoppered bottle, then add 3 Gm. of potassium iodide, securely stopper the bottle, and keep it at a temperature of 40° C. for thirty minutes. Then cool, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe." *U. S.*

Uses.—Ferric phosphate is one of the best preparations to use when it is desired to exhibit iron in solution. It is as free from astringency as any of the official salts of iron, has little tendency to disturb the digestion and is an active chalybeate.

The *dose* is from five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Elixir Cinchonæ Alkaloidorum et Ferri, *N. F.;* Elixir Ferri Phosphatis, *N. F.;* Elixir Gentianæ et Ferri Phosphatum, *N. F.;* Liquor Phosphatum Compositus, *N. F.;* Syrupus Ferri, Quininæ et Strychninæ Phosphatum, *N. F.*

FERRI PHOSPHAS SACCHARATUS. Br.

SACCHARATED IRON PHOSPHATE

"Saccharated Iron Phosphate is ferrous phosphate, more or less oxidised, mixed with glucose. It contains not less than 60 per cent. of ferrous salts calculated as ferrous phosphate, $Fe_3(PO_4)_2,8H_2O$." *Br.*

This preparation was introduced into the British Pharmacopœia, 1914, to replace the former "Ferri Phosphas" which was an insoluble slate-colored powder. The process is as follows: "Ferrous Sulphate, 120 *grammes;* Sodium Phosphate, 110 *grammes;* Sodium Carbonate, 50 *grammes;* Glucose, 40 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve twenty *grammes* of the Glucose in four hundred *millilitres* of the Distilled Water, and dissolve the Ferrous Sulphate in the solution. Dissolve the Sodium Phosphate in four hundred *millilitres* of the Distilled Water, and to this add the solution of the Ferrous Sulphate, stirring constantly. Then add the Sodium Carbonate previously dissolved in four hundred *millilitres* of the Distilled Water. Mix thoroughly, and allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with two successive quantities, each of two thousand *millilitres* of the Distilled Water, mix it with the remainder of the Glucose, and dry at a temperature not exceeding 100° C. Powder the product and preserve it in a stoppered bottle. A slate-blue, amorphous powder. Taste sweetish, chalybeate. Partially soluble in *water,* soluble in *hydrochloric acid.* The acid solution yields blue precipitates with *solution of potassium ferrocyanide* and *solution of potassium ferricyanide;* when treated with *tartaric acid* and excess of *solution of ammonia,* and subsequently with *solution of magnesium ammonio-sulphate,* it yields a white granular precipitate. 1 gramme dissolved in excess of warm *concentrated phosphoric acid* does not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 35.9 millilitres of *N/10 solution of potassium bichromate* have been added. *Arsenic limit* 5 parts per million." *Br.*

Glucose is used to protect the ferrous phosphate from oxidation, which it does only partially. This iron phosphate must not be confounded with the soluble ferric phosphate of the U. S. P.

The British iron phosphate, 1898, was a very different salt. By double decomposition ferrous phosphate and sodium sulphate are produced, the former precipitating as a white bulky powder, which soon changes on exposure to a greenish-blue, and ultimately to a slate color; since the sodium phosphate is chemically an acid salt (Na_2HPO_4) a portion of phosphoric acid is liberated during the reaction, and this, retaining in solution some of the ferrous phosphate, requires the addition of the solution of sodium bicarbonate to neutralize it and set free the remainder of the ferrous phosphate. This salt, when first formed, is represented by the formula $Fe_3(PO_4)_2$; but its strong affinity for oxygen causes the gradual production of a sesquisalt, which, therefore, to a certain extent, always exists in the preparation.

Uses.—Ferric phosphate possesses the general properties of the ferruginous preparations, and has been given with advantage in *amenorrhea* and *dyspepsia.*

Dose, from five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Syrupus Ferri Phosphatis, *Br.;* Syrupus Ferri Phosphatis cum Quinina et Strychnina, *Br.;* Elixir Cinchonæ Alkaloidorum et Ferri, *N. F.;* Elixir Gentianæ et Ferri Phosphatis, *N. F.;* Liquor Phosphatum Compositus, *N. F.;* Syrupus Ferri, Quininæ et Strychninæ Phosphatum, *N. F.*

FERRI PYROPHOSPHAS SOLUBILIS. N. F.

FERRIC PYROPHOSPHATE Ferr. Pyrophos. Sol. [Soluble Ferric Pyrophosphate]

"Ferric Pyrophosphate, rendered soluble by the presence of sodium citrate, corresponding to not less than 10 per cent. of Fe." *N. F.*

Ferri Pyrophosphas; Soluble Ferric Pyrophosphate; Ferri Pyrophosphas Solubilis, *U. S. P. VIII;* Iron Pyrophosphate; Pyrophosphate of Iron; Ferri et Sodii Citro-pyrophosphas; Ferrum Pyrophosphoricum cum Sodio Citrico; Pyrophosphate of Iron with Sodium Citrate; Sodio-ferric Citro-pyrophosphate; Pyrophosphate de Fer et de Soude, *Fr.;* Pyrophosphorsaures Eisenoxyd mit Citronensaurem Natron, *G.*

The process formerly official for this salt was: "Ferric Citrate, *fifty grammes;* Sodium Pyrophosphate, uneffloresced, *fifty grammes;* Distilled Water, *one hundred cc.* Dissolve the Ferric Citrate in the Distilled Water, by heating on a water-bath. To this solution add the Sodium Pyrophosphate, and stir constantly, until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60° C., to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.*, 1890.

Ferric pyrophosphate consists probably of sodio-ferric pyrophosphate, sodio-ferric citrate, and free ferric citrate. Sodio-ferric pyrophosphate, dried at 100° C., is considered by Flückiger (*Pharm. Chem.*, 2d ed., p. 607, 1888) to have the following composition: $Fe_4(P_2O_7)_3 + 3Na_4P_2O_7 + 14H_2O$.

Description and Physical Properties.—"Soluble Ferric Pyrophosphate occurs in thin, apple-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air, when protected from light, but when unprotected soon becomes discolored. It is freely and completely soluble in water; insoluble in alcohol. An aqueous solution of the salt is slightly acid to litmus.

"Ferric Pyrophosphate, when warmed with sodium hydroxide T.S., produces a brownish red precipitate without evolving ammonia. Fuse 0.1 Gm. of the salt with 0.1 Gm. each of potassium nitrate and sodium carbonate, boil the residue with 10 cc. of distilled water and filter. The filtrate, after being rendered nearly, but not quite neutral with highly dilute nitric acid, yields a yellow precipitate on the addition of silver nitrate T.S.

"Boil an aqueous solution of the salt (1 in 10) with an excess of sodium hydroxide T.S. until the iron is precipitated, filter, strongly acidulate the filtrate with hydrochloric acid and cool. This liquid when mixed with an equal volume of magnesia mixture T.S., followed by a slight excess of ammonia water, yields a finely divided white precipitate, which, after collecting on a filter and washing, does not turn yellow when treated with a few drops of silver nitrate T.S. (*phosphate*).

"**Assay.**—Dissolve about 1 Gm. of Soluble Ferric Pyrophosphate, accurately weighed, in 25 cc. of distilled water and 15 cc. of hydrochloric acid, in a glass-stoppered bottle, add 2 Gm. of potassium iodide, securely stopper the bottle, keep it at a temperature of 40° C. for thirty minutes, cool and then titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

"Preserve it in well-closed containers, protected from light." *N. F.*

Iron pyrophosphate is a good chalybeate, without disagreeable taste or astringency, and, from its solubility, readily administered in any form that may be desirable, whether that of pill, simple solution in water or syrup.

Dose, two to ten grains (0.13 to 0.65 Gm.).

Off. Prep.—Elixir Ferri Pyrophosphatis, Quininæ et Strychninæ, *N. F.*

FERRI SULPHAS. U. S., Br.

FERROUS SULPHATE Ferr. Sulph. [Iron Protosulphate]

"Ferrous Sulphate contains not less than 54.36 and not more than 57.07 per cent. of anhydrous ferrous sulphate, corresponding to about 99.5 per cent. of the crystallized salt [$FeSO_4.7H_2O$]." *U. S.* "Ferrous Sulphate may be prepared by the interaction of diluted sulphuric acid and iron. It contains not less than 97.5 per cent. of pure ferrous sulphate, $FeSO_4,7H_2O$." *Br.*

Sulphate of Iron, Green Vitriol, Iron Vitriol, Sulfas Ferrosus, Ferrum Vitriolatum Purum, Vitriolum Martis Purum; Sulphas Ferri; Sulfate Ferreux, Sulfate (protosulfate) de Fer, *Fr.;* Sulfate de Protoxyde de Fer, *Fr. Cod.;* Ferrum Sulfuricum, *P. G.;* Ferrosulfat, Schwefelsaures Eisenoxydul, *G.;* Solfato ferroso, *It.;* Sulfato ferroso, *Sp.*

A process for this salt was given in the U. S. P., 1870, which was based upon the method of Bonsdorff. This chemist found that, when a ferrous sulphate was formed in solution by heating diluted sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to prevent the formation of any sesquioxide during the process, at the same time avoiding, as much as possible, contact with the air. Hence the directions in the former U. S. Pharmacopœia formula to acidulate with sulphuric acid; to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air; and to cover the vessel containing the concentrated liquid when it is set aside to crystallize.

As prepared by Bonsdorff's method, ferrous sulphate is blue, verging upon green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of subsulphate, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. The aqueous solution is bluish-green, but by standing it attracts oxygen, and becomes first green and then reddish depositing in the meantime a portion of sesquisulphate, having the composition:

$$Fe_2(SO_4)_3 + Fe_2O_3 + 8H_2O$$

At a red heat it loses its acid, and is converted into the anhydrous ferric oxide called *colcothar.*

Commercial Ferrous Sulphate, or *Copperas,* is manufactured on a large scale for the purposes of the arts, from the native ferric sulphide or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and ferrous and ferric oxides, which, by their union, form the salt. Ferrous sulphate is also obtained in many chemical processes as a collateral or by-product, as in the manufacture of alum, in the precipitation of copper from solutions of copper sulphate by scraps of iron, in the manufacture of hydrogen, etc.

Commercial ferrous sulphate is far from being pure. Besides containing some ferric sulphate, it is generally contaminated with metallic and earthy salts, such as those of copper, zinc, aluminum, and magnesium. Two principal kinds occur in the market, one in large grass-green crystals, the surface of which is studded with yellow spots; the other of a bluish-green color, and ordinarily mixed with the powder of the effloresced salt.

Description and Physical Properties.—"Pale, bluish-green, monoclinic prisms. It is odorless, and has a saline, styptic taste. The salt is efflorescent in dry air, but on exposure to moist air, the crystals rapidly oxidize and become coated with brownish-yellow, basic ferric sulphate. When it has thus deteriorated, the salt must not be used for any official or medicinal purpose. One Gm. of Ferrous Sulphate is soluble in 1.4 cc. of water at 25° C. and in 0.4 cc. of boiling water. It is insoluble in alcohol. When slowly heated to 115° C., the crystals disintegrate and the salt loses the greater part of its water of crystallization.

"An aqueous solution of the salt (1 in 20) is acid to litmus paper. Ferrous Sulphate responds to the reactions for ferrous salts, and for sulphates. Dissolve 1 Gm. of the salt in about 50 cc. of distilled water containing 1 cc. of diluted sulphuric acid, heat the solution to boiling, oxidize it with nitric acid, mix it with a slight excess of ammonia T.S., and filter: the filtrate is colorless and after acidulating with hydrochloric acid meets the requirements of the test for *heavy metals.* Agitate 1 Gm. of Ferrous Sulphate, in small fragments, during four or five minutes with 10 cc. of alcohol, and filter the mixture: the filtrate does **not** immediately redden moistened blue litmus paper (*free acid*).

"Preserve in well-closed containers.

"**Assay.**—Dissolve about 1 Gm. of Ferrous Sulphate, accurately weighed, in 25 cc. of diluted sulphuric acid, and titrate with tenth-normal potassium permanganate until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.01519 Gm. of $FeSO_4$." *U. S.*

"Oblique rhombic prisms of a greenish color, or a crystalline powder of a pale bluish-green color; taste astringent. Insoluble in *alcohol* (90 per cent.), soluble in less than 2 parts of *water* previously boiled and cooled, giving a clear solution (absence of oxysulphate). Yields the *reactions* characteristic of ferrous salts and of sulphates. 1 gramme dissolved in 20 millilitres of *diluted sulphuric acid* decolorises not less than 35 millilitres of *N/10 solution of potassium permanganate.* Yields no characteristic *reactions* for copper or zinc. *Arsenic limit* 2 parts per million." *Br.*

Ferrous sulphate is incompatible with alkalies and their carbonates, soaps, lime water, calcium and barium chlorides, sodium borate and phosphate, silver nitrate, and lead acetate and subacetate. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesqui-oxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. It is incompatible also with even feeble oxidizing agents which quickly convert it into ferric sulphate or subsulphate.

Uses.—Ferrous sulphate is an active local irritant and astringent. In overdoses it produces nausea, vomiting, griping, and purging, and other evidences of gastro-enteric irritation. Because of this action it is not to be recommended as an internal remedy. Externally, the solution has been used in chronic *ophthalmia, leucorrhea,* and *gleet,* made of various strengths, from one or two to eight or ten grains of the salt to the fluidounce of water. Velpeau has recommended in *erysipelas* the local use of a three per cent. solution applied by compresses kept constantly wet. An ointment made of one or two parts of the sulphate to sixty of lard was found by Devergie to be particularly efficacious in certain skin diseases, especially in *eczema.* In scaly affections it had no effect. (See *Ferri Sulphas Exsiccatus.*)

Ferrous sulphate, usually in the impure form known commercially as copperas, has been used extensively as a disinfectant and deodorant. Its germicidal value is certainly low, Sternberg having found that a 20 per cent. solution was not certainly fatal to bacteria after two hours' exposure, and Leitz, that a 5 per cent. solution required three days for the destruction of typhoid bacilli. Its deodorant properties, however, are quite marked, due probably to its power of combining either with hydrogen sulphide or ammonia. It is asserted that ferric sulphate unites with organic substances to form definite stable compounds, and that animal substances kept in a 3 per cent. solution of neutral ferric sulphate for some time and then removed, mummify without decomposition. (*N. R.,* Dec., 1883, 685.)

Dose, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Ferri Carbonas Saccharatus, *U. S., Br.;* Ferri Phosphas Saccharatus, *Br.;* Ferri Sulphas Exsiccatus, *U. S., Br.;* Ferri Sulphas Granulatus, *U. S.;* Liquor Ferri Subsulphatis, *N. FERRI SULPHAS EXSICCATUS. U. S., Br.

EXSICCATED FERROUS SULPHATE Ferr. Sulph. Exsic. [Dried Ferrous Sulphate]

"Exsiccated Ferrous Sulphate contains the equivalent of not less than 80 per cent. of anhydrous ferrous sulphate [$FeSO_4$]." *U. S.* "Exsiccated Ferrous Sulphate is Ferrous Sulphate deprived of part of its water of crystallization. It contains not less than 77 per cent. of pure anhydrous ferrous sulphate, $FeSO_4$." *Br.*

Ferri Sulphas Exsiccata, *Br.*, 1885; Dried Sulphate of Iron; Sulfate Ferreux desséché, *Fr.;* Ferrum Sulfuricum Siccum, *P. G.;* Getrochnetes Ferrosulfat, Entwässertes Schwefelsaures Eisenoxydul, *G.;* Sulfato ferroso desecado, *Sp.*

"Ferrous Sulphate, in coarse powder, 100 Gm. Allow the salt to effloresce at a temperature of about 40° C. in dry air, and then heat it in a tared porcelain dish on a water bath, constantly stirring, until the product weighs from 64 to 65 Gm. Reduce the residue to a fine powder, and transfer it at once to dry bottles, which should be stoppered immediately." *U. S.*

The reason for the preliminary drying at a lower temperature than is subsequently employed is to prevent the melting of the salt in its full water of crystallization which greatly retards the process when it occurs.

In this process about six molecules out of seven, of the water of crystallization of the salt, are driven off. The heat in the earlier stages should be gentle to avoid liquefaction of the salt and subsequent difficulty in exsiccation, and in the latter stages of the process should not exceed 149° C., otherwise the salt itself would suffer decomposition. If the heat has been excessive, the color of the salt will be brownish instead of grayish-white.

No process is given in the British Pharmacopœia, 1914.

Description and Physical Properties.—"A grayish-white powder, slowly soluble in water. A solution of the salt (1 in 20) in recently boiled distilled water is not more than slightly turbid, and when taken in proportionate amount, conforms to the reactions and tests under *Ferri Sulphas,* except the test for free acid.

"Preserve in tightly-stoppered bottles." *U. S.*

"A nearly white powder, slowly but entirely soluble in *water.* 0.5 gramme dissolved in *water* and acidified with *sulphuric acid* decolorises not less than 25.3 millilitres of *N/10 solution of potassium permanganate. Arsenic limit* 5 parts per million." *Br.*

Assay.—"Dissolve about 0.8 Gm. of Exsiccated Ferrous Sulphate, accurately weighed, in 25 cc. of diluted sulphuric acid, and titrate with tenth-normal potassium permanganate until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.01519 Gm. of $FeSO_4$.

"Each cc. of tenth-normal potassium permanganate V.S. used corresponds to 0.015191 Gm. of $FeSO_4$. Each gramme of Exsiccated Ferrous Sulphate corresponds to not less than 52.7 cc. of tenth-normal potassium permanganate V.S." *U. S.*

Dried ferrous sulphate is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that about three grains of it are equivalent to five grains of the crystallized salt.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Pilulæ Aloes et Ferri, *Br., N. F.;* Pilula Ferri, *Br.;* Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ, *N. F.*

FERRI SULPHAS GRANULATUS U. S.

GRANULATED FERROUS SULPHATE Ferr. Sulph. Gran. [Precipitated Ferrous Sulphate]

Granulated Sulphate of Iron; Ferri Sulphas Præcipitatus, *U. S. P.*, 1880; Precipitated Sulphate of Iron; Sulfate Ferreux précipite, *Fr.;* Prăcipitirtes Ferrosulfat, *G.*

"Ferrous Sulphate, 100 Gm.; Distilled Water, 100 cc.; Diluted Sulphuric Acid, 5 cc.; Alcohol, 25 cc. Add the diluted sulphuric acid to the distilled water, heat to boiling, dissolve the ferrous sulphate in the liquid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain dish on a sand bath until it weighs 150 Gm., and cool it quickly with constant stirring. Transfer the product to a glass funnel fitted with a pledget of purified cotton, and when it has thoroughly drained pour the alcohol upon it. When this has also drained, spread the crystalline powder on bibulous paper, dry it quickly at room temperature, and transfer it at once to dry bottles, which should be stoppered immediately." *U. S.*

The process of the U. S. P. (1890), retained by the U. S. P., differs radically in manipulation from that of 1880; instead of pouring the filtered solution of ferrous sulphate into alcohol and collecting the precipitate which falls, the solution is granulated by heat with constant stirring (not quite to dryness), and this salt is then washed with alcohol, which displaces impurities and facilitates the rapid drying of the granular powder.

Description and Physical Properties.—"A pale bluish-green, crystalline powder, which meets the requirements of the tests for identity and purity and the assay under *Ferri Sulphas.*

"Preserve in tightly-stoppered bottles." *U. S.*

This salt is less liable to oxidation on exposure than is the sulphate in its ordinary form, and experience has shown that it is admirably adapted for dispensing.

Dose, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Pilulæ Ferri Carbonatis, *U. S.*

FERRUM. U. S., Br.

IRON Ferr.

"Metallic iron in the form of fine, bright wire." *U. S.* "Iron is annealed iron wire, having a diameter of about 0.1 millimetre (about No. 35 wire gauge), or wrought-iron nails, free from oxide. *Arsenic limit* 200 parts per million." *Br.*

Fer métallique, *Fr. Cod.;* Fil de Fer, *Fr.;* Eisen, Eisendraht, *G.;* Ferro, Limatura di ferro, *It.;* Hierro, *Sp.*

In the U. S. Pharmacopœia, this metal is employed in different preparations in the form of wire; it was official in 1850 as *Ferri Ramenta, Iron Filings.* See *U. S. Dispensatory,* 19th edition, p. 514.

Iron is one of the most abundant and useful of the metals, and so interwoven with the wants of mankind that the extent of its consumption by a nation may be taken as an index of progress in civilization. It is universally diffused in nature, not only in the mineral but also in the vegetable and animal kingdoms. There are very few minerals in which traces of it are not to be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are not deleterious to the animal economy. Iron occurs: (1) native (almost exclusively, however, of meteoric origin); (2) as a sulphide, in the minerals *pyrites, pyrrhotite,* or *magnetic pyrites,* and *arsenopyrite* or *mispickel* (a sulpharsenide of iron); (3) oxidized, embracing the magnetic, specular, red, brown, and argillaceous iron oxides which include *hæmtite, limonite,* etc., also *chromite* (mixed iron, chromium, and magnesium oxides), *siderite,* a ferrous carbonate, and *franklinite* (mixed iron, manganese and zinc oxides); (4) in saline combination, forming ferrous carbonate, sulphate, phosphate and arsenate. Those minerals of iron which admit of being worked to advantage are called *iron ores.* These include the different native oxides and the carbonate (spathic iron). The best iron is obtained from the ferroso-ferric oxide usually called magnetic iron ore, and the anhydrous sesquioxide, known as specular iron ore. These occur abundantly in Sweden, and furnish the superior iron of that country. The upper peninsula of Michigan and the borders of Lake Champlain in New York yield similar ores. As a rule, those ores which occur in primitive formations yield the best iron.

Extraction.—The mode of extracting iron from its ores varies somewhat with the nature of the ore; but the general principles of the operation are the same for all. The ore, previously broken into small pieces and roasted, is exposed to the action of an intense heat, urged by an air blast, in contact with carbonaceous matter, such as charcoal, coke, or anthracite, and in connection with some flux capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally limestone. Fluorspar is occasionally used, but is not often found in sufficiently large deposits to be available. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag, which is a fusible lime silicate chiefly, while the carbon monoxide formed from the carbonaceous matter, acting on the ferric oxide, reduces it to the metallic state. The reduced metal, from its density, occupies the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out by a hole in the side of the furnace, and the melted metal by an aperture at the bottom, the latter being received into a series of sand moulds, where it solidifies in masses, known in commerce by the name of *pig* or *cast iron.* In this state the metal is brittle and far from being pure, as it contains from 3 to 6 per cent. of carbon, with silicon, phosphorus, sulphur, and manganese. It is purified, and brought to the state of *malleable iron,* by being fused and subjected, while stirred, to the action of a current of air on its surface. By these means the carbon is nearly burnt out, and the other impurities are oxidized and made to rise to the surface as a slag. Instead of this process, called "refining," usage in this country and in England substitutes what is called "pig boiling"—that is, the pig iron is at once submitted to the operation of puddling without previous refining. The "puddling" process consists in heating the charge of pig iron on the hearth of a reverberatory furnace in contact with ferric oxide and in a reducing flame. The silicon is first burnt out, and then the carbon gradually disappears; the phosphorus goes into the "tap cinder" as phosphide and phosphate; the sulphur in part disappears as sulphur dioxide and in part remains in the cinder as ferrous sulphide. As the metal approaches to purity, it becomes tough and less liquid, and its particles agglutinate so as to form semi-fused lumps, though the temperature of the furnace continues the same. These lumps are then taken out of the furnace, and their particles, by means of ponderous hammers moved by steam or water power, or by great pressure, are forced together so as to form one tenacious mass. The metal is finally rolled out into bars of a convenient size, when it constitutes *wrought iron* of commerce.

The third form of commercial iron, known as "steel," is made either by the *cementation* process, the *Bessemer* process, the *open hearth* process, or by *electrical* processes. In the first case, wrought iron is packed with charcoal and heated until combination takes place, and the resulting steel is cast into ingots. In the second case, cast iron is melted in large vessels called converters, when a blast of air is blown through the mass, burning out the requisite amount of carbon, and then, after addition of a small amount of *spiegeleisen,* or manganiferous cast iron, the finished product is run into moulds; while in the third or open hearth process, a mixture of pig iron and ore is heated with a reverberatory flame, as in the puddling process, or bars and blooms of wrought iron are heated with the pig iron, and steel is made by the combination of the two. Steel contains from ½ to 1 per cent. of carbon.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish spathic iron and the red oxide. The chief iron ores of France are the spathic iron, and the specular, brown, and argillaceous oxides; of Germany, the spathic iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular iron ore. In the United States iron is abundant. The principal ores that are worked are the magnetic, red, and brown oxides. The magnetic oxide is found in large beds in Essex County, N. Y., on the borders of Lake Champlain, and in the Lake Superior district; the red oxide in New York, New Jersey, Pennsylvania, Alabama, and especially in a very pure state in Missouri, at Iron Mountain and Pilot Knob.

Properties.—Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a characteristic taste, and a sensible odor when rubbed. In tenacity it yields only to nickel and cobalt. (Deville.) Its sp. gr. is about 7.7, and its fusing point very high, about 1510° C. It possesses magnetic properties and is very malleable. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a yellowish-brown matter, called *rust,* which is a complex hydrated oxide of iron. It combines with all the non-metallic elements, except hydrogen and nitrogen, and with most of the metals. It forms three compounds with oxygen, a ferrous oxide and a ferric oxide, which by their union form the native magnetic oxide, hence often termed ferroso-ferric oxide, and a trioxide, which forms an acid called ferric acid. The *monoxide,* or ferrous oxide, is of a dark blue color, attracted by the magnet, and spontaneously combustible in the air, being converted into sesquioxide or ferric oxide. It is the base of ferrous sulphate, and the green salts of iron generally. It is very prone to absorb oxygen, and hence the salts which contain it are soon partially converted, when in solution, into ferric salts. Its formula is FeO. The *sesquioxide,* or *ferric oxide,* is readily obtained by dissolving iron in nitrohydrochloric acid, precipitating by ammonia, and igniting the precipitate. It is of a red color, not attracted by the magnet, and forms salts which for the most part have a reddish color. Its formula is Fe_2O_3. The *native black oxide,* the magnetic oxide of mineralogists, consists of one molecule of FeO and one molecule of Fe_2O_3.

Under the name of *Ferri Oxidum Magneticum,* the British Pharmacopœia formerly had a preparation consisting of this oxide with three molecules of water. *Ferric acid,* discovered by Frémy, may be obtained, in union with potassium hydroxide, by passing chlorine through a very concentrated solution of the alkali, holding the hydrated ferric oxide in suspension, or by fusing iron filings with potassium nitrate. Iron forms a number of important salts.

Iron is readily detected, even in minute quantities, by oxidation to the ferric condition, and adding potassium ferrocyanide or tincture of galls, the former of which will produce a deep blue, the latter a black color. In an interesting series of articles published in the *Scientific American,* Suppl. 2192 and 2193 (1918) the experiences of an iron atom are described, which brings in the entire history of the manufacture and uses of iron.

The so-called *stainless-steel* or *rustless-iron* is one of the alloys of iron, usually one containing chromium. Silicon is also used to the extent of about 15 per cent. in making a form of iron which is resistant to the action of acids. *Tantiron* and *Duriron* are ferro-silicon alloys of this character.

Uses.—The only condition in which the value of iron, as an internal remedy, has been proven beyond cavil is in certain types of *anemia.* The conditions of the blood which are characterized by a reduction in the percentage of hemoglobin may be divided into three groups, those in which the number of corpuscles is reduced to a greater extent than the percentage of hemoglobin—each individual corpuscle, therefore, being richer than normal in coloring matter—secondly, those in which the reduction in the number of corpuscles and the quantity of hemoglobin is approximately equal, and thirdly, those in which the number of corpuscles is not reduced as much as the percentage of hemoglobin—each corpuscle being poor in coloring matter. The first condition is seen typically in cases of pernicious anemia; the second in the so-called accidental anemias, those which are due to hemorrhage, wasting diseases, etc.; and the third is seen in chlorosis. The value of iron in any individual case of impoverishment of the blood is in proportion as the condition approaches the chlorotic type. In true *pernicious anemia,* iron is probably of no value at all, in the accidental or secondary anemia, it is often of considerable service, provided the cause of the blood impoverishment can be removed, and in true *chlorosis* it almost reaches the height of a specific.

Some years ago, certain chemists, failing to find any increase in the amount of iron in the urine after the administration of the inorganic salts of iron by the mouth, were led to believe that these forms of iron were not absorbable from the intestinal tract, and the theory had at one time a considerable number of adherents. It would carry us beyond the proper bounds of an article for the Dispensatory to go into all the evidence for and against the absorbability of iron, and the reader interested in the details is referred to H. C. Wood, Jr.'s *Pharmacology*. The subject may be summed up for the present purposes with the statement that it has been as firmly established as any fact in pharmacology, that the inorganic salts of iron are absorbed through the intestinal walls, and exercise a direct influence upon the blood making organs. That the amount of iron in the urine is not increased is owing to the fact that the great bulk of the metal is eliminated through the intestinal glands; this is true whether the drug be given by the mouth or hypodermically. Because of the former vogue for the theory of the non-absorption of iron, various chemists were led to place upon the market preparations in which the iron is bound up with organic matter in a non-ionizing form; these are spoken of as "organic iron" or "masked iron," and supposed to be more assimilable than the pharmacopœial salts. There is no convincing evidence that any of these preparations has any advantage over the inorganic salts, except, perhaps, a little less liability to disturb digestion. Indeed, the experiments of Abderhalden (*Z. B.*, 1900, xxxix) indicate that the iron in organic combination is of less value for the treatment of anemia than when in the inorganic form. Because iron is an essential constituent of the hemoglobin, it was formerly almost universally believed, and still is to a considerable extent, that it acted in anemia as a food-stuff. This belief has for its base mere assumption; and the infinitesimal amount of iron which is consumed in the human body, as well as the fact that patients with chlorosis are not cured by feeding upon the food rich in iron, throws great doubt upon this ancient legend, and the experiments of Abderhalden, quoted above, furnish almost conclusive proof of its error. It is far more probable that the action of iron is due to a stimulating effect upon the blood making organs analogous to the stimulant action of caffeine upon the kidneys, or strychnine upon the spinal cord.

The question of the selection of a preparation of iron for an individual case is often one of great importance. If it be simply desired to combat anemia, a preparation should be selected which is free as may be from astringency. Most of the liquid preparations of iron are more or less injurious to the teeth, so that commonly it is preferable to give a solid salt in pill or capsule rather than one of the liquid forms, unless the latter be especially indicated.

Certain salts of iron are extremely astringent and more or less irritant. The most important of these are the sulphates and the chlorides. These salts should never be employed as chalybeates, except in those cases in which, for some reason, astringency is desired. In some cases some laxative should be combined with iron to overcome its constipating influence.

The hypodermic use of iron suggested a number of years ago by Kobert of Dorpat has in the past decade come into a very wide popularity. When large quantities of iron—corresponding to twenty or thirty grains for a man—are injected hypodermically, it causes toxic symptoms and may even prove fatal. Although after large doses a considerable proportion is eliminated through the kidney and may exercise an irritating effect on this organ, the observations of Quincke (*A. E. P. P.*, 1896, xxxvii) and others show that after therapeutic quantities, the greater proportion is eliminated through the intestinal glands, and there is, therefore, relatively little danger of renal irritation. The favorite preparation of iron for hypodermic use is some form of ferric citrate. Sometimes the local reactions have been so severe as to entirely preclude the use of the drug. According to Stieglitz (*Am. J. Anat.*, 1921, xxix, p. 33), these reactions are due to a deficiency in ammonium, and he recommends the use of a ferric and ammonium citrate, representing not less than 8.1 per cent. of ammonia. Such a salt under the name of *green iron citrate* has been recognized by the N. N. R.

When used subcutaneously the dose must be much smaller than that ordinarily given by mouth (see under *Ferri et Ammonii Citras*). It is stated that after the hypodermic injection of large doses the irritation of the alimentary canal is more severe than when the drug is given by the mouth—a statement which finds confirmation in the experiments of Gottlieb, who found that when he injected iron subcutaneously into a dog he was able to obtain nearly 97 per cent. of it from the feces. The effort at intestinal elimination is evidently accompanied by irritation if the amount of iron to be eliminated is large.

FERRUM ALBUMINATUM. N. F.

ALBUMINIZED IRON Ferr. Album. [Iron Albuminate]

"Albuminized Iron is a compound of iron oxide and albumin, rendered soluble by the presence of sodium citrate. It contains not less than 17 per cent. and not more than 19 per cent. of Fe." *N. F.*

Under the name of "albuminate of iron" there have been used in medicine a variety of preparations made from egg albumen and either the chloride or oxychloride of iron. The exact form in which the iron exists in these compounds is not known; indeed, it probably differs according to the divergent methods of manufacture. The solution in the process of the German Pharmacopœia, 35 parts of dried albumen is dissolved in 1000 parts of water, to this is added 120 parts of the solution of iron oxychloride (*Liquor Ferri Oxychloratum,* P. G.)—previously diluted with 1000 parts of water; the resulting precipitate is washed and dissolved in dilute solution of sodium hydroxide, or it may be rendered soluble by means of sodium citrate as required by the N. F.

Description and Physical Properties.—"Reddish brown, lustrous granules, or a brown powder. It is odorless, or has not more than a slight odor. Albuminized Iron is freely soluble in water yielding dark solutions. It is almost insoluble in alcohol.

"The addition of acids to an aqueous solution of Albuminized Iron produces a precipitate which dissolves by warming with an excess of hydrochloric acid. The resulting solution yields the reactions characteristic of ferric iron. An aqueous solution of Albuminized Iron (1 in 20) is neutral or slightly alkaline to litmus paper. An aqueous solution (1 in 50) yields no blue color upon the addition of potassium ferrocyanide T.S. (absence of *ionic iron*).

"Dissolve 1 Gm. of Albuminized Iron in 50 cc. of distilled water. Render the solution slightly alkaline, if necessary, by the addition of sodium hydroxide T.S., and precipitate the iron from the solution with hydrogen sulphide. Filter, add to the filtrate 5 cc. of diluted hydrochloric acid and evaporate almost to dryness on the water bath. Dissolve the residue in 10 cc. of distilled water, and to 5 cc. of the solution, rendered slightly alkaline with sodium hydroxide, add 2 cc. of alkaline cupric tartrate solution and heat. No red precipitate is produced (*sugar*).

"**Assay.**—Weigh accurately about 0.5 Gm. of Albuminized Iron and ignite it in a crucible to destroy the organic matter. Allow to cool, transfer the residue completely into a beaker, add 10 cc. of hydrochloric acid, heat until all the iron is dissolved, then add 10 cc. of hydrogen dioxide T.S., and evaporate almost to dryness on the water bath. Dissolve the residue by warming with 5 cc. of hydrochloric acid and 10 cc. of water and transfer the solution completely into a glass-stoppered flask, filtering if necessary, and washing the residue, and filter with small quantities of hot water until free from iron. Now add to the solution 3 Gm. of potassium iodide, allow to stand for one-half hour at about 40° C., cool and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of iron (Fe)." *N. F.*

Uses.—While this preparation is an eligible chalybeate there is no evidence that it possesses any real advantage over some of the older salts of the metal.

Dose, from five to ten grains (0.3–0.6 Gm.).

Off. Prep.—Liquor Ferri Albuminati, *N. F.*

FERRUM PEPTONATUM. N. F.

PEPTONIZED IRON Ferr. Pepton. [Iron Peptonate]

"Peptonized Iron is a compound of iron oxide and peptone, rendered soluble by the presence of sodium citrate. It contains not less than 16 per cent. and not more than 18 per cent. of Fe." *N. F.*

Several formulas for preparing compounds of iron with peptone have been suggested. Dieterich's is made by treating a 10 per cent. aqueous solution of peptone (100 parts) with *Liquor Ferri Oxychlorati,* P. G. (120 parts), exactly neutralize with sodium hydroxide solution; the resulting precipitate decomposed with hydroxide may be dissolved by means of sodium hydroxide citrate and the solution evaporated, forming brownish yellow granules. In the original method the precipitated peptonate was dissolved with the aid of hydrochloric acid.

Description and Physical Properties.—"Dark brown, lustrous granules, or a brown powder. It has a slight characteristic odor. Peptonized Iron is freely soluble in water yielding dark solutions. It is almost insoluble in alcohol.

"The addition of acids to an aqueous solution of Peptonized Iron produces a precipitate which dissolves upon warming with an excess of hydrochloric acid. The resulting solution yields the reactions characteristic of ferric iron. An aqueous solution of Peptonized Iron (1 in 20) is neutral or slightly alkaline to litmus paper. An aqueous solution (1 in 50) yields no blue color upon the addition of potassium ferrocyanide T.S. (absence of *ionic iron*).

"Dissolve 1 Gm. of Peptonized Iron in 50 cc. of distilled water, render the solution slightly alkaline, if necessary, by the addition of sodium hydroxide T.S., and precipitate the iron from the solution with hydrogen sulphide. Filter, add to the filtrate 5 cc. of diluted hydrochloric acid and evaporate almost to dryness on the water bath. Dissolve the residue in 10 cc. of distilled water, and to 5 cc. of the solution, rendered slightly alkaline with sodium hydroxide, add 2 cc. of alkaline cupric tartrate solution and heat. No red precipitate is produced (*sugar*).

"**Assay.**—Weigh accurately about 0.5 Gm. of Peptonized Iron and ignite it in a crucible to destroy the organic matter. Allow to cool, transfer the residue completely into a beaker, add 10 cc. of hydrochloric acid, heat until all the iron is dissolved, then add 10 cc. of hydrogen dioxide T.S., and evaporate almost to dryness on the water bath. Dissolve the residue by warming with 5 cc. of hydrochloric acid and 10 cc. of water, and transfer the solution completely into a glass-stoppered flask, filtering, if necessary, and washing the residue and filter with small quantities of hot water until free from iron. Now add to the solution 3 Gm. of potassium iodide, allow to stand for one-half hour at about 40° C., cool and titrate the liberated iodine with tenth-normal sodium thiosulphate. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of iron (Fe)." *N. F.*

Uses.—This preparation of iron is nearly free from astringency or tendency to disturb digestion but it is doubtful whether it possesses any real advantage over the citrate or soluble phosphate.

Dose, three to eight grains (0.2–0.5 Gm.).

FERRUM REDUCTUM. U. S. (Br.)

REDUCED IRON Ferr. Reduct. [Iron by Hydrogen, Quevenne's Iron]

"Reduced Iron is obtained by the action of hydrogen upon ferric oxide and contains not less than 90 per cent. of metallic iron [Fe]." *U. S.* "Reduced Iron may be obtained by reducing ferric hydroxide, heated to dull redness, by means of a stream of dry hydrogen. It contains not less than 80 per cent. of metallic iron, with a variable amount of iron oxide." *Br.*

Ferrum Redactum, *Br., U. S.* 1870; Ferri Pulvis, *U. S.* 1850; Powder of Iron; Ferrum Hydrogenio Reductum, Ferrum Ope Hydrogenii Paratum; Iron Reduced by Hydrogen; Fer réduit par l'Hydrogène, *Fr. Cod.;* Ferrum reductum, *P. G.;* Reduzirtes Eisen, *G.;* Ferro ridotto dall' idrogeno, *It.;* Hierro reducido por el hidrogeno, *Sp.*

A process for this form of iron is no longer given in the United States Pharmacopœia. (See *U. S. Dispensatory,* 19th edition, page 518.)

This preparation consists of metallic iron in fine powder, obtained by reducing the ferric oxide by hydrogen at a dull red heat. The compound of iron formerly called the subcarbonate which is essentially the ferric oxide, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from hydrogen sulphide and acid compounds by passing successively through a solution of lead subacetate and milk of lime. The hydrogen unites with the oxygen of the ferric oxide to form water, and leaves the iron in the metallic state. The ferric oxide should be perfectly free from sodium sulphate, which it is likely to contain when imperfectly washed. If this salt be present, it will be reduced by the hydrogen to the state of sodium sulphide, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken internally to give rise to unpleasant eructations. The heat should be carefully regulated, for if it fall below dull redness, part of the oxide will escape reduction, and if it exceed that point considerably, the particles of reduced iron will agglutinate, and the preparation will be heavy and not readily pulverizable.

Under the name of *"alcoholized iron,"* a powdered iron was at one time sold in this country, said to be prepared, in the eastern parts of Germany, by attrition of iron filings with honey, by some cheap method, as by attachment to a saw mill or steam machinery. It had the appearance of powdered plumbago, but under the magnifying glass was seen to contain particles with metallic luster and rounded as if by friction. It was soluble in diluted sulphuric acid, with the escape of hydrogen, free, or nearly so, from sulphur, but a small quantity of black powder remained undissolved. The relation of the epithet "alcoholized" to this powder is an example of an unusual use of the word alcohol, which in the Arabic means "very finely divided." The word alcoholize, therefore, simply means to reduce to an impalpable powder and has been so used since its first use by Phillips in 1706.

Other forms of finely divided iron which have been produced by mechanical or electrical processes and not by the reduction method, have been offered at various times to take the place of reduced iron or even under the name of the latter substance, but are therapeutically inferior to the official form.

Description and Physical Properties.—"An odorless, grayish-black, lusterless powder, all of which must pass through a No. 100 sieve. When viewed under a lens having a magnifying power of one hundred diameters, Reduced Iron appears as an amorphous powder, free from crystalline particles. It is stable in dry air. Reduced Iron is insoluble in water and in alcohol.

"Heat about 1 Gm. of Reduced Iron in a porcelain crucible with a small Bunsen flame until it assumes a bluish-black color without glowing. Then quickly pour it from the crucible: the particles of iron will glow brightly as they fall through the air. Shake 1 Gm. of Reduced Iron with 5 cc. of distilled water, and filter: the filtrate does not change the color of litmus paper. Treat 1 Gm. of Reduced Iron with 20 cc. of diluted sulphuric acid and when the reaction subsides, heat gently until no more gas is evolved. Filter, wash the residue with distilled water until the washings cease to react for sulphate, dry at 110° C. to constant weight, and weigh. The weight of the residue should not exceed 0.010 Gm. One Gm. of Reduced Iron mixed with 20 cc. of diluted sulphuric acid in a flask causes the evolution of nearly odorless hydrogen gas, which does not affect paper moistened with lead acetate T.S. within two minutes (*sulphide*). Add 20 cc. of diluted sulphuric acid to 0.5 Gm. of Reduced Iron contained in a small, covered beaker, and after the reaction has subsided somewhat warm the liquid on a water bath until the reaction ceases. Pass the solution through a small filter to collect any undissolved residue, rinse the beaker with distilled water, add the rinsings to the filter, and then wash the residue with distilled water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, and after adding about 0.25 Gm. of potassium chlorate and 5 cc. of hydrochloric acid, slowly evaporate the solution to dryness on a water bath. Dissolve the residue in sufficient distilled water to measure 50 cc., add 5 cc. of this solution to 5 cc. of a saturated solution of sulphurous acid, and heat the liquid on a water bath for fifteen minutes, or until all traces of sulphurous acid have been removed: the resulting solution meets the requirements of the test for *arsenic*.

"Preserve in well-closed containers." *U. S.*

"A fine greyish-black powder, strongly attracted by the magnet, and producing metallic streaks when rubbed with firm pressure in a mortar. Dissolves in *hydrochloric acid* with evolution of hydrogen, and without any odor of hydrogen sulphide, the solution giving a light-blue precipitate with *solution of potassium ferrocyanide.* When 0.25 gramme, in very fine powder, is added to a hot solution of 1.25 grammes of *copper sulphate* in 20 millilitres of *water,* the mixture kept hot and occasionally well shaken during ten minutes, and then rapidly filtered with the minimum of exposure to air, the filtrate decolorises not less than 35.8 millilitres of *N/10 solution of potassium permanganate.* Not more than 1 per cent. is insoluble in *hydrochloric acid. Arsenic limit* 200 parts per million." *Br.*

Assay.—"Triturate thoroughly about 1 Gm. of Reduced Iron, weigh accurately, place it in a 100 cc. flask, and add 10 Gm. of finely powdered corrosive mercuric chloride and 50 cc. of boiling distilled water. Boil the mixture for five minutes, shaking it frequently, then fill the flask to the 100 cc. mark with distilled water, recently boiled and cooled, and cool the mixture to room temperature. Again fill the flask to the mark with distilled water, stopper, agitate the contents well, and allow to stand for a few minutes. Now filter the contents of the flask, and immediately titrate 20 cc. of the filtrate to which has been added 20 cc. of diluted sulphuric acid, with tenth-normal potassium permanganate, until a permanent pink color is produced. Each cc. of tenth-normal potassium permanganate corresponds to 0.005584 Gm. of Fe." *U. S.*

O. E. Winter (*J. A. P. A.*, 1913, p. 296) presents a critical review of the methods and requirements in all existing pharmacopœias and compares the efficiency of the various official methods for the determination of the iron. He favors the mercuric chloride method adopted in the U. S. P., when accompanied by a limiting test for sulphides, which when present in large amounts, interferes with the accuracy of the method.

Uses.—Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard, of Paris. When of official quality it is an excellent chalybeate, being especially serviceable for administration in pills because of its concentrated condition and lack of astringency. A mechanically powdered iron, made from factory waste, is sometimes fraudulently substituted for the official form, but is greatly inferior in its therapeutic action; the value of the official form is due to the very fine division of the particles of iron by virtue of which it can be dissolved in the fluids of the alimentary tract.

Dose, one to three grains (0.065–0.20 Gm.) several times a day, given in powder or in pill.

FICUS. N. F.

FIG

"Ficus is the clean, sound, partially dried fruit of *Ficus Carica* Linné (Fam. *Moraceæ*)." *N. F.*

Caricæ; Ficus Passa; Fructus Caricæ; Figue, *Fr. Cod.* Feigen, *G.;* Fichi, *It.;* Higos, *Sp.*

The genus *Ficus* yields a number of economic products. Many species possess a milky juice containing caoutchouc (see *Elastica*); some possess anthelmintic properties, as *F. anthelmintica* Mart.; some yield shellac (see *Lac*); and some are esteemed for their fruits, as *F. Carica* L., *F. religiosa* L., etc.

Ficus Carica, or fig tree, though often not more than twelve feet high, sometimes rises in warm climates twenty-five or even thirty feet. Its trunk, which seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-colored bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining above, pale green and downy beneath, and stand alternately on strong, round petioles. The flowers are situated within a common receptacle, placed upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seed-like bodies found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicles. Cultivation has produced in the fig, as in the apple and peach, a great diversity in shape, size, color, and taste. It is usually, however, turbinate, or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish color, and of a mild, mucilaginous, saccharine taste. The dried figs can be partially restored to their original shape by soaking. The fig tree is native to Western Asia. It was introduced at a very early period into various parts of the south of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. Large numbers of Syrian fig cuttings were planted in the Pomona Valley, California, in 1882, and California figs are now commercial articles. Many varieties of figs are now being cultivated throughout the coastal plain from Texas to the Carolinas chiefly for home consumption, canning and preserving. For details of fig culture see *Bull. 732 U. S. Dept. Agric., 1918.* To hasten the ripening of the fruit, it is customary to puncture it with a sharp pointed instrument covered with olive oil. *Caprification* consists in attaching branches of the wild fig tree—or caprifig—to the cultivated plant. The fruit of the former contains great numbers of the eggs of a small wasp, *Blastophaga glossorum,* the larvæ of which, as soon as they are hatched, spread themselves over the unripened receptacle of the cultivated fig, enter its hollowed interior through a narrow terminal aperture, and, by conveying the pollen to the inclosed female florets, hasten the impregnation of the latter, and cause to quickly come to perfection the fig which might otherwise ripen very slowly, or wither and drop off before maturity.

The chief commercial sources of the figs used in this country are Smyrna and California. They are gathered when fully ripe and dried in the sun or in ovens. Smyrna figs are imported in boxes or drums containing from ½ to 20 kilos, in which they are carefully packed, and also, in string clusters packed in sacks. The individual figs are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which softens in the middle of summer and renders them moist. The best or Suzini grade are yellowish or brownish, somewhat translucent when held to the light, and filled with a sweet viscid pulp, in which are lodged numerous small yellow achenes. They are much more saccharine than is the fresh fruit. Their chief constituents are grape sugar, and gum or mucilage.

Description and Physical Properties.—"*Whole Fig.*—Usually compressed, of irregularly rounded shape, from 2.5 to 5 cm. in diameter, fleshy, light brown to yellow, frequently with an efflorescence of sugar; apex with a small, scaly orifice; base with a scar or short stalk; internally hollow, with numerous small, brownish yellow, glossy, hard achenes. Odor distinctive, fruity; taste sweet, pleasant.

"*Structure.*—Epidermal cells of receptacle thick-walled up to 0.020 mm. in diameter, some being modified into tapering, unicellular epidermal hairs with a rounded base up to 0.060 mm. in diameter and 0.300 mm. in length, others modified into broadly elliptical stomata up to 0.035 mm. in length; hypodermis consisting of several layers of small cells with thick walls frequently containing rosettes of calcium oxalate, the latter up to 0.020 mm. in diameter; remaining tissue of receptacle chiefly of large parenchyma cells containing sugar, branching latex cells and tracheæ having spiral or reticulate markings. Achenes yellowish; broadly rounded at one end and rounded or straight pointed at the other, up to 1.550 mm. in length and 1.400 mm. in width; pericarp characterized by outer layer of thin-walled cells and an inner layer of stone cells, the latter rounded or angular; seed-coat thin, yellowish; endosperm composed of thick-walled cells containing fixed oil, aleurone grains and few starch grains; embryo curved." *N. F.*

An average of several analyses of dried figs as quoted by Königs (*Nahrungs und Genussmittel,* 3te Aufl., Bd. i, 781) gives—water, 31.20; nitrogenous material, 4.01; sugar, 49.79; ash, 2.86. Reckoned on the weight of absolutely dry material, the nitrogenous matter amounted to 5.75 per cent. and the sugar to 72.26 per cent. According to Landerer, the unripe fig contains an irritant juice, which inflames the skin, and may even disorganize it. (See *A. J. P.,* xxxiii, 215.) They are officially described as

Uses.—Figs are nutritious, laxative, and demulcent. In the fresh state they are considered, in the countries where they grow, a wholesome and agreeable aliment, and have been employed from time immemorial. They are prone, however, when eaten freely, to produce flatulence, pain in the bowels, and diarrhea. The latex of the fig has been used as an anthelmintic against intestinal parasites. Their chief medicinal use is as a laxative article of diet in *constipation.* They occasionally enter into demulcent decoctions, and, roasted or boiled, and split open, are sometimes applied as a cataplasm to inflamed gums.

FLUIDEXTRACTA. U. S. (Br.)

FLUIDEXTRACTS

"Fluidextracts are concentrated liquid preparations of vegetable drugs, containing alcohol either as a solvent or as a preservative, and bearing a uniform relation to the drugs used so that 1 cc. of the fluidextract closely represents the useful constituents of 1 Gm. of the air dried and powdered drug of standard quality." *U. S.*

Extracta Liquida, *Br.;* **Fluid Extracts; Extraits liquides,** *Fr;* Extracta fluida, *P. G.;* Fluidextrakte, Flüssige Extrakt, *G.*

The Latin title Extractum —— Fluidum formerly used for fluidextracts was dropped by the U. S. P. VIII because of the confusion which resulted from the necessary bringing together of the extracts and fluid extracts due to a strict alphabetical arrangement; the name "fluidextractum" is now used for "fluidextract" and the latter made one word.

Fluidextracts were first introduced into the U. S. P. of 1850. They are now perhaps the most important class of liquid preparations in use. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form, a cubic centimeter of any one of them representing a gramme of the crude drug.

It has been repeatedly proposed to make 50 per cent. tinctures or half-strength fluidextracts, the main object being to secure more representative preparations when made on the small scale. Experiments by Sayre, Gregory, Patch, and others prove that half-strength fluidextracts possess no advantages over those of official strength. (*D. C.*, 1897, 119, 147.)

Fluidextracts U. S. P. X.

"The fluidextracts of this Pharmacopœia, with few exceptions, may be classified according to the menstruum used in the extraction of the drugs and the processes of manufacture employed. Several drugs require special manipulation to obtain satisfactory fluidextracts, and for these appropriate formulas have been devised and are printed in full in the text. In the preparation of fluidextracts by the appended type processes A, B, or C, the rate of percolation must be carefully controlled and, for the quantities directed in the formulas of the Pharmacopœia, the flow should not exceed ten drops per minute until the percolate to be reserved is collected, and twenty drops per minute thereafter. One thousand Gm. of powdered drug may frequently be exhausted by percolation with sufficient menstruum to yield 3000 cc. of percolate, but, in all cases the percolation should be continued until the drug is practically exhausted. Fluidextracts should be kept in tightly-stoppered, amber-colored bottles, protected from sunlight and extremes of temperature. After keeping for one month, the clear portion should be decanted from any sediment, the remainder filtered, and the liquids thoroughly mixed before storing.

"The percentage of alcohol in fluidextracts made by type processes A, B, or C, is variable and always less than that in the menstruum employed, due, among other causes, to loss of alcohol by evaporation during manufacture, the presence of a variable proportion of water in the air-dried drug, and to the extraction from the drug of its soluble constituents, which also often vary greatly in different lots of the same drug. The percentage of alcohol in the finished product can therefore only be ascertained by an actual determination." *U. S.* (See *Alcohol Determination*, Part III.)

"*Type Process A.*—This process is recommended for fluidextracts that are made with a menstruum of alcohol, or a mixture of alcohol and water, by the usual process of percolation. Moisten 1000 Gm. of the powdered drug directed with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to so maintain it during maceration for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum until the drug is exhausted. Reserve the first 850 cc. of the percolate (unless otherwise specified in the formula), recover the alcohol from the remainder of the percolate, and concentrate the residue to a soft extract at a temperature not exceeding 60° C. Dissolve the extract in the reserved portion, mix thoroughly, and finally add a sufficient quantity of the menstruum to make the fluidextract measure 1000 cc., or the volume determined by calculation from the assay.

"*Type Process B.*—This process is recommended for fluidextracts in which glycerin or an acid is used in the extraction and two menstrua are successively employed. Moisten 1000 Gm. of the powdered drug directed with a sufficient quantity of the prescribed Menstruum I to render it evenly and distinctly damp and to so maintain it during maceration for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, add the remainder of Menstruum I, and when this has just disappeared from the surface, gradually add Menstruum II, constantly maintaining a stratum of liquid above the drug. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours, and then allow the percolation to proceed slowly, gradually adding Menstruum II until the drug is exhausted. Reserve the first 850 cc. of the percolate (unless otherwise specified in the formula), recover the alcohol from the remainder of the percolate, and concentrate the residue to a soft extract at a temperature not exceeding 60° C. Dissolve the extract in the reserved portion, mix thoroughly, and finally add a sufficient quantity of Menstruum II to make the fluidextract measure 1000 cc. or the volume determined by calculation from the assay.

"*Type Process C—Fractional or Divided Percolation.*—This process is especially recommended for drugs containing volatile constituents or constituents which are injured by exposure to heat. This process may also be used as an alternative process in the formulas in which Type Process A is directed. Divide 1000 Gm. of the powdered drug directed into three portions of 500 Gm., 300 Gm., and 200 Gm., respectively. Moisten the first portion of the drug (500 Gm.) with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to so maintain it during maceration for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours, and then allow the percolation to proceed slowly, gradually adding more of the menstruum. Reserve the first 200 cc. of percolate, and continue the process until the additional percolate measures 1500 cc., the latter being collected in successive portions of 300 cc. Moisten the second portion of the powdered drug (300 Gm.) with a sufficient quantity of the percolate collected in the preceding operation, immediately after the reserved portion, to render it evenly and distinctly damp and to so maintain it during maceration for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, macerate, and percolate as directed for the first portion of the drug, using as menstruum the several portions of percolate from the preceding operation in the order in which they were collected, and, if this is insufficient, follow with more of the original menstruum. Reserve the first 300 cc. of percolate, and continue the process until the additional percolate measures 800 cc., the latter being collected in successive portions of 200 cc. each. Moisten the third portion of the powdered drug (200 Gm.), with a sufficient quantity of the percolate collected in the preceding operation, immediately after the reserved portion, to render it evenly and distinctly damp and to so maintain it during maceration for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, macerate, and percolate as before, using as menstruum the several portions of percolate from the preceding operation in the order in which they were collected, and, if this is insufficient, follow with more of the original menstruum. Collect 500 cc. of percolate, and mix this with the two portions previously reserved to make 1000 cc. of finished fluidextract. When Type Process C is directed for fluidextracts which are adjusted by assay to a definite alkaloidal standard, collect only 420 cc. of percolate from the third portion of drug instead of the 500 cc. directed above. Mix this percolate with the two portions previously reserved, assay a portion of the mixture and adjust its volume by the addition of the menstruum directed so that each 100 cc. of finished fluidextract will contain the prescribed amount of alkaloid.

"*Type Process D.*—This process is recommended for those fluidextracts in which extraction is effected by infusion and percolation with boiling water, alcohol being added to the concentrated liquid as a preservative. To 1000 Gm. of the ground drug add 5000 cc. of boiling water, mix thoroughly, and allow it to macerate in a covered container in a warm place for two hours. Then transfer the moist drug to a tinned or enameled metallic percolator, and allow percolation to proceed, gradually adding boiling water until the drug is exhausted. Evaporate the percolate on a water bath or steam bath to the volume specified, and when cold add the alcohol directed, and mix thoroughly. Allow the product to stand for seven days in a stoppered container, then decant the clear liquid, filter the remainder, and wash the residue on the filter with sufficient of a mixture of alcohol and water in the proportion used to make the fluidextract measure 1000 cc." *U. S.*

The precipitation experienced when the evaporated weak percolate was added to the reserved portion, is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluidextracts, was due to the greater volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this was added to the strongly alcoholic reserved portion, a precipitation of resinous, and frequently of active matter, took place, which necessitated the storing of the fluidextract until precipitation ceased, and subsequent filtration. This is not altogether avoided by evaporating to a soft extract, but the loss of activity through precipitation is thus greatly diminished. Fluidextracts invariably deposit insoluble matter upon standing, and those made in warm weather, owing to the greater solvent powers of the menstrua (due to the elevated temperature) are found to deposit more freely than the same kind of fluidextracts if made in the winter time with menstrua correspondingly reduced in temperature.

The reason for the apparent stability of the fluidextracts furnished by the large scale manufacturer, is that sufficient reserve stock is kept on hand to permit this precipitation to take place before marketing the products.

In the earlier formulas for fluidextracts in the U. S. P. glycerin was used too lavishly in the menstrua and many of the preparations were loaded with inert extractive matter. Scoville (*J. A. Ph. A.*, 1920, ix, 868) has completed a study of the function of glycerin in the menstrua of fluidextracts and tinctures and points out the fact that glycerin in some cases must be considered as a solvent, and in others as a stabilizer. In some cases, as in a few of the alkaloidal and astringent drugs, it is a distinct disadvantage, as it retards extraction.

A useful distillatory apparatus has been contrived by Joseph P. Remington for recovering alcohol from weak percolates, and for general pharmaceutical uses. (See *Practice of Pharmacy.*)

Fluidextracts are mostly prepared by percolation (see under *Extracta*) but in a few instances maceration yields satisfactory results.

Several methods have been suggested for preparing fluidextracts more economically. The use of acetic acid as a menstruum to replace alcohol or diluted alcohol has the merit of economy. (See *Extracta,* also *A. J. P.*, 1899, 1, 67; *Proc. Pennsylvania Pharm. Assoc.,* 1898, 116; *Ph. Era,* 1898, 796; *Proc. Minnesota Pharm. Assoc.,* 1902, 103; *West. Drug.,* 1903, 652.)

The most important modification is the plan of *repercolation,* as proposed by E. R. Squibb, for this class of preparations as well as the dry extracts.

This process consists in the successive application of the same percolating menstruum to fresh portions of the substances to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the substance, becomes concentrated to the greatest possible extent, so that much of the menstruum is saved, while subsequent evaporation is avoided. Repercolation is officially permitted, by the U. S., as an alternative process, and is generally employed by wholesale manufacturers.

H. Biroth (*Pharm.*, April, 1877) proposed the method which he termed *"insuccation,"* for making non-alcoholic fluidextracts; the advantages claimed for it are simplicity and economy. Colaz prepared fluidextracts from fresh plants by bruising and crushing them, and placing the mass in a dialyzer suspended in 90 per cent. alcohol; when the dialysis is completed, the liquid is evaporated to free it from alcohol, the remaining aqueous liquid retaining the active constituents in the proportions in which they are found in the plant. (*Ph. Post,* xxix, 271.)

For other methods which have been suggested for economizing alcohol—most of which have been abandoned—see *U. S. D.,* 20th ed., p. 482.

Assaying Fluidextracts.—The U. S. gives assay processes for the fluidextracts of alkaloidal drugs; these differ but slightly from the process used for the corresponding drug; they will be found in the succeeding pages under their appropriate headings.

A new method of assay for alkaloidal fluidextracts, especially adapted to the mydriatic leaf drugs in that the interfering chlorophyll is removed, making only one shaking out operation necessary, was proposed by LaWall (*J. A. Ph. A.*, 1912, 29), as follows: Place 25 Gm. of sodium chloride in a 100 cc. graduated cylinder, with water sufficient to make 85 cc. Add 5 cc. of the fluidextract and 5 cc. of 10 per cent. ammonia water. Agitate well for 1 minute, then pour upon a dry filter and collect 50 cc. of clear filtrate, which can be shaken out as directed in the final shake out of the ordinary assay process, using the solvent directed for the particular drug which is being assayed. The method does not work with cinchona, guarana or other drugs containing large amounts of alkaloids in the form of cinchotannates.

The keeping quality of fluidextracts, judged from the alkaloidal content of those which are assayable, has been greatly overestimated. Scoville (*J. A. Ph. A.,* 1919, viii, 799) made an exhaustive study of the keeping qualities of about fifty fluidextracts and tinctures. He found that deterioration is largely due to the unstable nature of the alkaloids in many cases and to the precipitation of secondary constituents that also carry down alkaloids. In general, he says that any large amount of precipitation is accompanied by a loss of strength. Haussmann (*A. J. P.,* 1895, 291,) after examining a large number of commercial fluidextracts, finds great variation in the quality, due to deviation from pharmacopœial processes.

EXTRACTUM AGROPYRI FLUIDUM. Br.

LIQUID EXTRACT OF COUCH GRASS

Fluidextractum Tritici, *U. S. IX.;* Fluidextract of Triticum; Liquid Extract of Couch Grass; Liquid Extract of Triticum; Fluidextract of Couch-grass Root; Extrait liquide de petit Chiendent, *Fr.;* Flüssiges Queckenwurzelextrakt, *G.*

"Couch Grass, cut small, 1000 *grammes;* Distilled Water, boiling, 10,000 *millilitres;* Alcohol (90 per cent.), sufficient to product 1000 *millilitres.* Boil the Couch Grass with the Distilled Water for thirty minutes; strain; evaporate to seven hundred and fifty *millilitres;* cool and add sufficient of the Alcohol to produce the required volume; filter." *Br.*

This fluidextract is no longer recognized by the U. S., but is official in the N. F. (see *Fluidextractum Tritici,* Part III).

In making this fluidextract in warm weather, it is advisable to commence evaporating the percolate before the drug is exhausted, or fermentation may set in; triticum contains fermentable sugars, and diluted aqueous solutions do not keep well.

This fluidextract represents whatever virtues triticum possesses. The German Pharmacopœia formerly directed an *Extractum Graminis,* by digesting 1 part of Triticum with 6 parts of hot water, for six hours, straining, evaporating to a syrup, mixing 1 part of this extract with 4 parts of cold distilled water, filtering, and evaporating to an extract. The fluidextract is preferable, as the excessive use of heat is avoided.

Dose, from one to four fluidrachms (3.75–15 cc.).

EXTRACTUM BELÆ LIQUIDUM. Br.

LIQUID EXTRACT OF BAEL

"Bael Fruit, bruised, 1000 *grammes;* Chloroform Water, 15,000 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Macerate the bruised Bael Fruit for twelve hours in five thousand *millilitres* of the Chloroform Water; pour off and reserve the clear liquid; repeat the maceration a second and a third time for one hour in each case, using for each maceration five thousand *millilitres* of the Chloroform Water; press the marc; strain the mixed liquids through flannel. Evaporate to seven hundred and fifty *millilitres;* cool; add sufficient of the Alcohol to produce the required volume; filter." *Br.*

This represents whatever therapeutic virtues may reside in Bael Fruit. (See *Belæ Fructus.*)

Dose, one to two fluidrachms (3.75–7.5 cc.).

FLUIDEXTRACTUM BELLADONNÆ FOLIORUM. U. S.

FLUIDEXTRACT OF BELLADONNA LEAVES

Fldext. Bellad. Fol.

"Fluidextract of Belladonna Leaves yields, from each 100 cc., not less than 0.27 Gm. and not more than 0.33 Gm. of the total alkaloids of belladonna leaves." *U. S.*

"Belladonna Leaves, in moderately coarse powder, 1000 Gm. Prepare a fluidextract by Type Process A, using a mixture of 3 volumes of alcohol and 1 volume of water as the menstruum, and reserving the first 800 cc. of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with sufficient menstruum to make each 100 cc. of the finished Fluidextract contain 0.3 Gm. of the alkaloids of belladonna leaves." *U. S.*

Assay.—"Proceed by Type Process D, taking 10 cc. of Fluidextract of Belladonna Leaves, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of belladonna (Proximate Assays)." *U. S.*

Alcohol content, by volume, 58 to 63 per cent.

The need for a fluidextract of belladonna leaves in addition to that of the root is not obvious. Its admission, in our opinion, is unfortunate as tempting careless pharmacists to make the tincture by dilution of the fluidextract instead of by the official method.

Dose, one to two minims (0.06–0.12 cc.).

FLUIDEXTRACTUM BELLADONNÆ RADICIS. U. S. (Br.)

FLUIDEXTRACT OF BELLADONNA ROOT
Fldext. Bellad. Rad.

"Fluidextract of Belladonna Root yields, from each 100 cc., not less than 0.405 Gm. and not more than 0.495 Gm. of the alkaloids of belladonna root." *U. S.* "Liquid Extract of Belladonna contains in 100 millilitres, 0.75 gramme of the alkaloids of Belladonna Root." *Br.*

Extractum Belladonnæ Liquidum, *Br.;* Liquid Extract of Belladonna; Extrait liquide de Racine de Belladonne, *Fr.;* Flüssiges Tollkirschenwurzelextrakt, *G.*

"Belladonna Root, in moderately coarse powder, 100 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 5 volumes of alcohol and 1 volume of water as the menstruum, and reserving the first 800 cc. of the percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough menstruum to make each 100 cc. of the finished Fluidextract contain 0.45 Gm. of the alkaloids of belladonna root." *U. S.*

"Belladonna Root, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), Distilled Water, of each, *a sufficient quantity.* Exhaust the Belladonna Root with a mixture of seven volumes of the Alcohol and one volume of Distilled Water by the *repercolation process* until from every three *grammes* of the Root one *millilitre* of strong percolate has been obtained." *Br.*

Assay.—"Proceed by Type Process D, taking 10 cc. of Fluidextract of Belladonna Root, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of belladonna (Proximate Assays).

"Alcohol content, by volume, 69 to 73 per cent." *U. S.*

"Determine the proportion of alkaloids in this strong percolate by the following process: Introduce into a separator 10 *millilitres* of the strong percolate, 50 *millilitres* of *water,* 2 *millilitres* of *diluted sulphuric acid,* and 10 *millilitres* of *chloroform.* Shake vigorously, set aside until complete separation has taken place, draw off the lower layer, and wash it with two successive portions, each of 10 *millilitres,* of *water* acidified with *diluted sulphuric acid.* Add the washings to the upper layer left in the separator. Make the mixture distinctly alkaline with *solution of ammonia,* and extract the alkaloids by shaking with three successive portions, each of 10 *millilitres* of *chloroform.* Mix the chloroformic solutions, shake with 10 *millilitres* of *water,* allow separation to take place, draw off the lower layer into a beaker, and set aside for the chloroform to evaporate. Heat the residue on a water-bath for thirty minutes, add 10 *millilitres* of *N/20 solution of sulphuric acid,* warm gently until dissolved, and titrate back with *N/20 solution of sodium hydroxide, tincture of cochineal* being used as indicator. Deduct the number of *millilitres* of alkaline solution required from 10; the remainder, multiplied by 0.01446, gives the number of *grammes* of the alkaloids contained in 10 *millilitres* of the strong percolate. To the remainder of the strong percolate add sufficient of the alcoholic menstruum to produce a Liquid Extract of Belladonna containing 0.75 *gramme* of the alkaloids of Belladonna Root in 100 *millilitres.* Examined by the foregoing process, Liquid Extract of Belladonna is found to contain in 100 millilitres 0.75 gramme of the alkaloids of Belladonna Root. *Limit of error* 0.05 gramme in excess or defect. This Liquid Extract contains 0.75 gramme of the alkaloids of Belladonna Root in 100 millilitres; 110 minims contain ¾ grain." *Br.*

The British liquid extract, 1914, represented several radical improvements in British pharmacy,—*i.e.,* the use of repercolation with absence of heat in the process, and standardization, thus making the end product bear a definite relation towards the quantity of active constituents found in the root (0.75 per cent.). It is based upon the formula proposed by R. A. Cripps. (*P. J.,* 1895, 795.) It will be observed that the alkaloidal standards of the U. S. and Br. Pharmacopœias are not identical; the U. S. fluidextract is made from the standardized drug (belladonna root) (0.45 per cent.); the British liquid extract is made from the *unstandardized* drug and hence the standard for the liquid extract can be made stronger (0.75 per cent.).

The fluidextract of the root is a good preparation, of reddish-brown color, very different in appearance from the deep-green fluidextract of the leaves.

Dose, from one to two minims (0.06–0.12 cc.) of the British liquid extract, not more than one minim (0.06 cc.).

Off. Prep.—Emplastrum Belladonnæ, *Br.;* Extractum Belladonnæ Siccum, *Br.;* Linimentum Belladonnæ, *N. F., Br.;* Unguentum Belladonnæ, *Br.*

FLUIDEXTRACTUM BUCHU. U. S.

FLUIDEXTRACT OF BUCHU Fldext. Buchu.

"Buchu, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum.

"Alcohol content, by volume, 78 to 84 per cent." *U. S.*

The menstruum selected for this fluidextract has been alcohol, although experience has shown that with the weaker alcohol used in the U. S. P. VIII formula it was possible to percolate buchu leaves satisfactorily. We prefer as a menstruum that of the U. S. P. VIII, *i.e.,* alcohol 3, water 1.

This fluidextract is of a dark green color, and shows in a high degree the sensible properties of the leaves. It acquires the odor of mint when long kept, showing that some change takes place in its volatile oil. This fluidextract affords the best means at our command for the exhibition of buchu.

Dose, thirty minims to a fluidrachm (1.8–3.75 cc.), three to five times a day.

Off. Prep.—Elixir Buchu, *N. F.;* Elixir Buchu et Potassii Acetatis, *N. F.;* Elixir Buchu, Juniperi et Potassii Acetatis, *N. F.*

FLUIDEXTRACTUM CANNABIS. U. S.

FLUIDEXTRACT OF CANNABIS Fldext. Cannab. [Fluidextractum Cannabis Indicæ, U. S. P. VIII]

"Fluidextract of Cannabis, administered by the mouth to dogs in doses not exceeding 0.1 cc. for each kilogram of body weight of dog, produces the same degree of incoördination as that produced by an equivalent dose of the standard fluidextract of cannabis, prepared as directed under *Cannabis.*" *U. S.*

Extrait liquide de Chanvre Indien, *Fr.;* Flüssiges Indisch-Hanfextrakt, *G.*

"Cannabis, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained adjust the volume of the finished Fluidextract by the addition of alcohol to conform to the above biological standard.

"**Assay.**—Proceed as directed under *Cannabis.* Alcohol content, by volume, 75 to 85 per cent." *U. S.*

Uses.—The fluidextract of cannabis represents the therapeutic virtues of that drug in a convenient form. The smallness of the dose is an advantage over the tincture and many believe that the extract is injured by the evaporation. It has been generally asserted that fluidextract of cannabis is subject to rapid deterioration but this view has not been scientifically confirmed by recent investigators. Hamilton (*J. A. Ph. A.,* 1918, vii, p. 117) tested a fluidextract seventeen years old and found a value of 70 per cent. of standard. But, whatever be the reason, commercial samples vary so greatly in power that it is impossible to assign the proper dose. The only satisfactory way to use it is to start in with doses of one or two minims, increasing each day until some effect is obtained.

Dose, one to four minims (0.06–0.25 cc.).

Off. Prep.—Collodium Salicylici Compositum, *N. F.*

FLUIDEXTRACTUM CASCARÆ SAGRADÆ. U. S. (Br.)

FLUIDEXTRACT OF CASCARA SAGRADA Fldext. Casc. Sagr. [Fluidextract of Rhamnus Purshiana]

Extractum Cascaræ Sagradæ Liquidum, *Br.;* Liquid Extract of Cascara Sagrada; Fluidextractum Rhamni Purshianæ, *U. S. VIII.;* Extrait liquide de Cascara Sagrada, *Fr.;* Flüssiges Cascara-Sagrada-extrakt, *G.*

"Cascara Sagrada, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process D. Evaporate the aqueous percolate to 750 cc., and when cold gradually add 250 cc. of alcohol and if necessary, sufficient water to make the product measure 1000 cc. Alcohol content, by volume, 20 to 24 per cent." *U. S.*

"Cascara Sagrada, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Exhaust the Cascara Sagrada with the Distilled Water by the *percolation process;* evaporate the percolate to six hundred *millilitres;* add the Alcohol previously mixed with one hundred and fifty *millilitres* of the Distilled Water, or with sufficient to produce the required volume." *Br.*

The emodin strength of this and similar preparations of cascara, which has been arbitrarily set by most manufacturers at 1.50 grammes in each 100 cc. of the fluidextract, may be estimated by the method of Vanderkleed and E'we (*Proc. Pa. Pharm. Assoc.,* 1913, p. 325).

A comprehensive study of the market fluidextracts of cascara was made by Westman and Rowat (*Bull. Lab. Int. Rev. Dept. of Canada* through *C. D.,* 1918, xc, 978). They give data on the examination of numerous samples and conclusions and recommendations based upon these data.

This preparation thoroughly represents the medicinal virtues of cascara sagrada. It is less pleasant but more efficient than the aromatic fluidextract.

Dose, fifteen minims to one fluidrachm (0.9–3.75 cc.).

Off. Prep.—Extractum Cascaræ Sagradæ Siccum, *Br.;* Syrupus Cascaræ Aromaticus, *Br.*

FLUIDEXTRACTUM CASCARÆ SAGRADÆ AROMATICUM. U. S.

AROMATIC FLUIDEXTRACT OF CASCARA SAGRADA Fldext. Casc. Sagr. Arom. [Aromatic Fluidextract of Rhamnus Purshiana]

Tasteless Fluidextract of Cascara Sagrada; Extrait liquid Aromatique de Cascara Sagrada, *Fr.;* Bitterloses flüssiges Cascara-Sagradaextrakt, *G.*

"Cascara Sagrada, in coarse powder, 1000.0 Gm.; Magnesium Oxide, 60.0 Gm.; Lime, 60.0 Gm.; Pure Extract of Glycyrrhiza, 40.0 Gm.; Glycerin, 200.0 cc.; Alcohol, 200.0 cc.; Gluside, 1.0 Gm.; Oil of Anise, 2.5 cc.; Oil of Cinnamon, 0.2 cc.; Oil of Coriander, 0.1 cc.; Methyl Salicylate, 0.2 cc.; Boiling Water, a sufficient quantity to make 1000 cc. Slake the lime by the gradual addition of water, mix it thoroughly with the cascara sagrada and the magnesium oxide, moisten uniformly with 2000 cc. of boiling water, set aside in a shallow dish for forty-eight hours, stirring occasionally, and then pack in a percolator. Now pour on boiling water and allow the percolation to proceed until the drug is exhausted. Evaporate the percolate to 500 cc., and while yet warm dissolve in it the pure extract of glycyrrhiza. When cold, add the glycerin, then the alcohol in which the gluside and the oils have been dissolved, and finally sufficient water to make the Fluidextract measure 1000 cc. Alcohol content, by volume, 17 to 19 per cent." *U. S.*

An aromatic fluidextract was introduced into the U. S. P. VIII for the first time. The object of the addition of magnesium and calcium oxides is to destroy the bitter taste of the cascara sagrada. It is not quite so actively cathartic as the plain fluidextract.

Dose, fifteen minims to one fluidrachm (0.9–3.75 cc.).

Off. Prep.—Elixir Cascaræ Sagradæ, *N. F.;* Elixir Cascaræ Sagradæ Compositum, *N. F.*

FLUIDEXTRACTUM CIMICIFUGÆ. U. S.

FLUIDEXTRACT OF CIMICIFUGA Fldext. Cimicif. [Fluidextract of Black Cohosh, Fluidextract of Black Snakeroot]

Extractum Cimicifugæ Liquidum, *Br.*, 1898; Liquid Extract of Cimicifuga; Liquid Extract of Actæa Racemosa; Extrait liquide d'Actée à Grappes, *Fr.;* Flüssiges Cimicifügaextrakt, *G.*

"Cimicifuga, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum. Alcohol content, by volume, 79 to 85 per cent." *U. S.*

There probably cannot be two opinions about the menstruum, although it has been asserted that a good fluidextract can be made with a menstruum of three parts alcohol and one part water. The probabilities are, however, that a portion of the resinous principle would precipitate on standing. This fluidextract is of a deep reddish-brown color, and thoroughly represents the drug.

Dose, from ten to thirty minims (0.6–1.8 cc.).

Off. Prep.—Elixir Sodii Salicylatis Compositum, *N. F.*

FLUIDEXTRACTUM CINCHONÆ. U. S. (Br.)

FLUIDEXTRACT OF CINCHONA Fldext. Cinchon.

"Fluidextract of Cinchona yields, from each 100 cc., not less than 4 Gm. and not more than 5 Gm. of the total alkaloids of cinchona." *U. S.* "Liquid Extract of Cinchona contains in 100 millilitres 5 grammes of the alkaloids of Red Cinchona Bark." *Br.*

Extractum Cinchonæ Liquidum, *Br.*, Liquid Extract of Cinchona; Extractum Chinæ Calisayæ Fluidum; Fluidextract of Calisaya Bark; Extrait liquide de Quinquina jaune, *Fr.;* Flüssiges Kalisayarinden extrakt, Flüssiges Chinaextrakt, *G.*

"Cinchona, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B (page 160), using a mixture of 100 cc. of glycerin, 100 cc. of diluted hydrochloric acid, and 800 cc. of alcohol as Menstruum I, and a mixture of 4 volumes of alcohol and 1 volume of water as Menstruum II. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough of Menstruum II to make each 100 cc. of the finished Fluidextract contain 4.5 Gm. of the total alkaloids of cinchona." *U. S.*

"Red Cinchona Bark, in No. 60 powder, 1000 *grammes;* Hydrochloric Acid, 31 *millilitres;* Glycerin, 125 *millilitres;* Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity.* Mix the Red Cinchona Bark with five thousand *millilitres* of the Distilled Water, to which the Hydrochloric Acid and Glycerin have been added; set aside in a covered vessel for forty-eight hours, stirring frequently; transfer to a percolator; when the liquid ceases to pass continue the percolation with Distilled Water until the percolate ceases to give a precipitate with excess of *solution of sodium hydroxide.* Evaporate the percolate in a porcelain or enamelled iron vessel at a temperature not exceeding 85° C., until it is reduced to one thousand *millilitres.*" *Br.*

Assay.—"Proceed by Type Process C, taking 5 cc. of Fluidextract of Cinchona, using 200 cc. of ether-chloroform mixture for maceration. Decant an aliquot portion of 160 cc., representing 4 cc. of Fluidextract of Cinchona, using chloroform for the final extraction, and determine the alkaloids gravimetrically (Proximate Assays).

"Alcohol content, by volume, 56 to 62 per cent." *U. S.*

"Determine the proportion of alkaloids in the liquid product by the following process: Transfer 5 *millilitres* to a stoppered glass separator; add 15 *millilitres* of *benzolated amylic alcohol* and 10 *millilitres of N/1 alcoholic solution of potassium hydroxide;* shake well, set aside in a warm place for a few minutes, shaking occasionally, and then allow the liquids to separate; pour off the clear upper layer into a second separator and repeat the shaking with two further portions of 15 and 10 *millilitres* of *benzolated amylic alcohol.* Shake the mixed alcoholic liquids with two portions, each of 5 *millilitres,* of *water,* and reject the aqueous liquid; then shake vigorously with a warm mixture of 12 *millilitres* of *diluted hydrochloric acid* and 60 *millilitres* of *water,* using three successive portions of 30, 30, and 12 *millilitres,* and drawing off the acid liquids into a separator. To this acid liquid add 15 *millilitres* of *chloroform* and distinct excess of *solution of ammonia,* shake vigorously, allow the liquids to separate and draw off the chloroformic layer into a tared dish; repeat the shaking and separating with further portions, each of 10 *millilitres,* of *chloroform* until the aqueous liquid, after acidification with *diluted sulphuric acid,* gives no further precipitate with *solution of potassio-mercuric iodide.* Add the chloroformic solutions to that in the dish, allow the chloroform to evaporate slowly; dry the residue in the dish at a temperature of about 110° C. and weigh. The weight of the residue is that of the total alkaloids in 5 *millilitres* of the liquid product. Having thus ascertained the alkaloidal strength of the liquid product, bring every volume of it containing 5 *grammes* of total alkaloids to eighty-five *millilitres,* either by evaporation or by dilution with Distilled Water as may be necessary, add twelve and a half *millilitres* of the Alcohol, and finally sufficient Distilled Water to produce one hundred *millilitres* of the Liquid Extract. Examined by the foregoing process, Liquid Extract of Cinchona is found to contain in 100 *millilitres* 5 grammes of the alkaloids of Red Cinchona Bark. *Limit of error* 0.2 gramme in excess or defect. This Liquid Extract contains 5 grammes of the alkaloids of Red Cinchona Bark in 100 millilitres; 110 minims contain 5 grains." *Br.*

The U. S. and Br. preparations are not made from the same variety of cinchona bark, the U. S. preparation being made from either the red or the yellow cinchona, while the Br. P. preparation is made from the red variety. The latter bark is much more difficult to extract.

Dose, five to twenty minims (0.3–1.3 cc.).

FLUIDEXTRACTUM COLCHICI. U. S.

FLUIDEXTRACT OF COLCHICUM Fldext. Colch. [Fluidextractum Colchici Seminis, U. S. P. IX]

"Fluidextract of Colchicum yields, from each 100 cc., not less than 0.36 Gm. and not more than 0.44 Gm. of colchicine." *U. S.*

Extrait liquide de Semences de Colchique, *Fr.;* Flüssiges Zeitlosensamenextrakt, *G.*

"Colchicum Seed, in moderately coarse powder, 1000 Gm.; Purified Petroleum Benzin, a sufficient quantity. Pack the colchicum seed in a cylindrical percolator, and slowly percolate with purified petroleum benzin until a few drops of the percolate leave no greasy stain when evaporated from filter paper. Reject the benzin solution, remove the powder from the percolator, and dry it by exposure to the air. Then proceed to make the Fluidextract by Type Process A, using a mixture of 2 volumes of alcohol and 1 volume of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough menstruum to make each 100 cc. of the finished Fluidextract contain 0.4 Gm. of colchicine." *U. S.*

Assay.—"Place 15 cc. of Fluidextract of Colchicum in a 500 cc. flask containing 275 cc. of distilled water, mix well, add 10 cc. of solution of lead subacetate, and agitate the mixture frequently during one hour. Filter off 200 cc. and proceed as directed under *Colchici Semen Assay,* beginning with the word 'Add.'

"Alcohol content, by volume, 53 to 58 per cent." *U. S.*

The present formula is an improvement over the older method, as the fixed oil is removed by the benzin treatment. L. I. Morris (*A. J. P.,* 1881, 7) believes that it is unnecessary to grind the colchicum seeds, and that if the whole seeds are digested with diluted alcohol at 80° C. the colchicine is easily extracted. It well represents the therapeutic virtues of colchicum seed.

Dose, two to eight minims (0.12–0.5 cc.).

FLUIDEXTRACTUM ERGOTÆ. U. S. (Br.)

FLUIDEXTRACT OF ERGOT Fldext. Ergot. [Secalis Cornuti Extractum Fluidum P. I.]

"Fluidextract of Ergot, administered by intramuscular injection to single-comb, white Leghorn cocks, in doses not exceeding 0.5 cc. for each kilogram of body weight of cock, produces a darkening of the comb, corresponding in intensity to that caused by the same dose of the standard fluidextract of ergot prepared as directed under *Ergota.*" *U. S.*

Extractum Ergotæ Liquidum, *Br.;* Liquid Extract of Ergot; Extrait liquide de Seigle ergoté, *Fr.;* Extractum Secalis Cornuti fluidum, *P. G.;* Mutterkorn-Fluidextrakt, Flüssiges Mutterkornextrakt, *G.*

"Ergot, recently ground and in coarse powder, 1000 Gm.; Purified Petroleum Benzin, a sufficient quantity. Pack the Ergot in a cylindrical percolator, and slowly percolate with purified petroleum benzin until a few drops of the percolate leave no greasy stain when evaporated from filter paper. Reject the benzin solution, remove the drug from the percolator, and dry it by exposure to the air. Then proceed to make the Fluidextract by Type Process B (page 160), using a menstruum of 20 cc. of hydrochloric acid and 980 cc. of diluted alcohol as Menstruum I, and diluted alcohol as Menstruum II. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained adjust the volume of the finished Fluidextract by the addition of enough Menstruum II to make it conform to the required biological standard.

"**Assay.**—Proceed as directed under *Ergota.*

Alcohol content, by volume, 37 to 42 per cent." *U. S.*

"Ergot, crushed, 1000 *grammes;* Distilled Water, 7500 *millilitres;* Alcohol (90 per cent.), 375 *millilitres.* Macerate the crushed Ergot with five thousand *millilitres* of the Distilled Water for twelve hours; strain; repeat the maceration with the remainder of the Distilled Water; press; strain; evaporate the mixed liquids to seven hundred *millilitres;* when cold, add the Alcohol; set aside for an hour; filter. The product measures about one thousand *millilitres.*" *Br.*

The Br. preparation is greatly inferior to the U. S. because of the use of an aqueous menstruum. It has been shown by Barger and Dale (*Biochem. J.*, 1907, ii, p. 286) and by Brown and Clark (*J. P. Ex. T.*, 1923, xxii, 59) that the Br. liquid extract is almost completely lacking in the characteristic alkaloid, ergotoxin.

An increase in the percentage of alcohol used in this fluidextract would have been an advantage, as some of the active principles of ergot are practically insoluble in water. Great care should be observed in the evaporation of the second portion of the percolate not to exceed the official temperature, 60° C. as the activity of ergot is seriously lessened by heating.

The U. S. fluidextract, when fresh, well represents the activity of ergot and is probably the best preparation of ergot on the market. Unfortunately, however, as shown by H. C. Wood, Jr. (*A. J. P.*, 1911, 172), it is subject to rapid deterioration. (For literature on this subject, see Eberhardt and Eldred, *J. A. Ph. A.*, 1914, iii, 38.) This loss of potency is accelerated by exposure to the air and the preparation should be stored in small containers which are kept tightly corked until used. Pittenger and Vanderkleed assert that by keeping the fluidextract in hermetically sealed vacuum tubes it will retain its activity almost indefinitely; but the figures they give do not entirely confirm their claim. Certainly the common custom of buying fluidextract of ergot, for retail dispensing, and pouring out a little now and then as it may be called for on prescriptions, can not be too severely condemned. Under such conditions the preparation may lose 50 per cent. of its power in less than six months.

Dose, from half a fluidrachm to two fluidrachms (1.8–8.0 cc.).

FLUIDEXTRACTUM ERIODICTYI. U. S.

FLUIDEXTRACT OF ERIODICTYON Fldext. Eriodict. [Fluidextract of Yerba Santa]

Extrait liquide d'Eriodictyon, *Fr.;* Flüssiges Eriodictyonextrakt, *G.*

"Eriodictyon, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 4 volumes of alcohol and 1 volume of water as the menstruum, and reserving the first 800 cc. of percolate.

"Alcohol content, by volume, 57 to 62 per cent." *U. S.*

For a process for Aromatic Fluidextract of Yerba Santa, see *U. S. D.*, 19th ed., p. 539.

This fluidextract has a dark brownish-green color, and has proven a valuable addition.

Dose, from fifteen minims to a fluidrachm (0.9–3.75 cc.).

Off. Prep.—Elixir Eriodictyi Aromaticum, *N. F.;* Syrupus Eriodictyi Aromaticus, *N. F.*

FLUIDEXTRACTUM EUCALYPTI. U. S.

FLUIDEXTRACT OF EUCALYPTUS
Fldext. Eucalypt.

Extrait liquide d'Eucalyptus, *Fr.;* Flüssiges Eucalyptusextrakt, *G.*

"Eucalyptus, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 3 volumes of alcohol and 1 volume of water as the menstruum, and reserving the first 800 cc. of percolate.

"Alcohol content, by volume, 58 to 63 per cent." *U. S.*

This fluidextract well represents the drug, and is of a dark greenish-brown color, having the peculiar odor and taste of eucalyptus very strongly developed, but in effectiveness it is much inferior to the volatile oil.

Dose, from ten to thirty minims (0.6–1.8 cc.).

FLUIDEXTRACTUM GLYCYRRHIZÆ. U. S. (Br.)

FLUIDEXTRACT OF GLYCYRRHIZA
Fldext. Glycyrrh.

Extractum Glycyrrhizæ Liquidum, *Br.;* Liquid Extract of Liquorice; Fluidextract of Licorice or Liquorice; Extrait liquide de Réglisse, *Fr.;* Flüssiges Süssholzwurzelextrakt, *G.*

"Glycyrrhiza, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process D. Promptly evaporate the aqueous percolate to 750 cc., allow this to cool, and gradually add 250 cc. of alcohol and, if necessary, sufficient water to make the product measure 1000 cc.

"Alcohol content, by volume, 20 to 24 per cent." *U. S.*

"Liquorice Root, in No. 20 powder, 1000 *grammes;* Chloroform Water, 5000 *millilitres;* Alcohol (90 per cent.), *a sufficient quantity.* Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water, and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C.; strain through flannel; evaporate until the liquid has acquired, when cold, a specific gravity of 1.200; add to this one-fourth of its volume of the Alcohol; let the mixture stand for twelve hours; filter." *Br.*

The process of the U. S. P. IX in which ammonia water was used in the original macerating liquid and the drug was subsequently exhausted with chloroform water has been superseded by a process in which the ammonia water has been omitted and the extraction is accomplished by percolation with boiling water, alcohol being subsequently added to stabilize and preserve the preparation. This change was made in the interests of both flavor and of stability. The former preparation was somewhat acrid and was frequently subject to precipitation. The use of boiling water as a menstruum and the subsequent concentration of this percolate by evaporation causes the precipitation of albuminous matter and other objectionable extractives which are thus renewed before the preparation is completed. The object of the use of chloroform water in the Br. process is to avoid fermentation during the extracting process. The British formula for the liquid extract has several inconvenient manipulative features, such as the repeated macerations and expressions, evaporating to a certain specific gravity, etc. (See *Mont. Pharm. Journ.*, 1893, 147; *P. J.*, 1898, 188.)

This preparation is now very largely used as an adjuvant, and for disguising the bitter taste of quinine, which should be added to the preparation of licorice just before the dose is taken. It is a very convenient form for using licorice. It is a dark brown liquid, having the sweet taste of licorice, and froths when shaken with water. A *syrup of licorice* may be made by adding two parts of fluidextract to fourteen parts of simple syrup. (See also *N. F.*, Part III.)

Used as a vehicle only.

Off. Prep.—Elixir Glycyrrhizæ, *U. S.;* Mistura Sennæ Composita, *Br.;* Syrupus Sarsaparillæ Compositus, *U. S.;* Elixir Glycyrrhizæ Aquosum, *N. F.;* Elixir Taraxaci Compositum, *N. F.*

EXTRACTUM GOSSYPII RADICIS CORTICIS LIQUIDUM. Br.

LIQUID EXTRACT OF COTTON ROOT BARK

"Cotton Root Bark, in No. 30 powder, 1000 *grammes;* Glycerin, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Mix the Glycerin with seven hundred and fifty *millilitres* of the Alcohol; moisten the Cotton Root Bark with this mixture and continue the *percolation process,* using as menstruum first the remainder of the mixture of Glycerin and Alcohol, and afterwards sufficient of the Alcohol to produce the required volume." *Br.*

The fluidextract of cotton root bark was not retained in the U. S. but the National Formulary has introduced a fluidextract made from the recently gathered air-dried bark of the root, using alcohol for the menstruum. (See Part III.) The British process requires the use of glycerin which may have a tendency to prevent gelatinization.

Uses.—There is reason to believe that cotton-root bark loses some of its activity in drying. For this reason the preparation of the N. F. is to be preferred to the Br. For therapeutic properties of cotton root, see *Gossypii Radicis Cortex.*

Dose, one-half to one fluidrachm (1.8–3.75 cc.).

FLUIDEXTRACTUM GRANATI. U. S.

FLUIDEXTRACT OF POMEGRANATE

Fldext. Granat.

Fluidextract of Pomegranate Root Bark; Extrait liquide d'Ecorce de Balaustier, Extrait liquide d'Ecorce de Grenadier, *Fr.;* Flüssiges Granatwurzelrindenextrakt, *G.*

"Pomegranate, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B (page 160), using a mixture of 100 cc. of glycerin, 500 cc. of alcohol and 400 cc. of water as Menstruum I, and diluted alcohol as Menstruum II.

"Alcohol content, by volume, 34 to 40 per cent." *U. S.*

This fluidextract well represents the virtues of pomegranate but is less used than the alkaloids.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

EXTRACTUM GRINDELIÆ LIQUIDUM. Br.

LIQUID EXTRACT OF GRINDELIA

Fluidextractum Grindeliæ, *U. S. IX.;* Liquid Extract of Grindelia; Extrait liquide de Grindélia, *Fr.;* Flüssiges Grindelienextrakt, *G.*

"Grindelia, in No. 40 powder, 1000 *grammes;* Sodium Bicarbonate, 100 *grammes;* Distilled Water, 500 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Grindelia by *percolation* with the Alcohol. Recover the alcohol from the percolate by distillation, and dissolve the residue in the Distilled Water, to which the Sodium Bicarbonate has previously been added; after effervescence has ceased, add sufficient Distilled Water to produce seven hundred and fifty *millilitres,* and then sufficient of the Alcohol to produce the required volume." *Br.*

A fluidextract of Grindelia is recognized by the N. F. (see Part III).

This is a fluidextract which well represents the drug; owing to the large quantity of resinous matter present, it does not mix well with aqueous liquids. The so-called *"alkaline fluid extract of grindelia"* may be made by evaporating one pint of official fluidextract until reduced to twelve fluidounces, making a solution of 180 grains of sodium bicarbonate in four fluidounces of water, adding it slowly to the evaporated fluidextract, and filtering; the British liquid extract is made upon this principle. The fluidextract is a dark brown liquid having the peculiar odor of grindelia.

For medical properties and uses, see *Grindelia.*

Dose, ten to thirty minims (0.6–1.8 cc.).

EXTRACTUM HAMAMELIDIS LIQUIDUM. Br.

LIQUIDEXTRACT OF HAMAMELIS

Fluidextractum Hamamelis Foliorum, *N. F.;* Fluidextract of Hamamelis Leaves; Fluidextract of Witch-hazel Leaves; Extrait liquide de Hamamélis, *Fr.;* Flüssiges Hamamelis-extrakt, *G.;* Extracto fluido de hamamelis, *Sp.*

"Hamamelis Leaves, dried, in No. 40 powder, 1000 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the

Hamamelis Leaves by *percolation* with the Alcohol. Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This liquid extract well represents the virtues of witchhazel. The fluidextract of hamamelis leaves is not recognized by the U. S., but will be found in the N. F. (See Part III.) It has a dark reddish-brown color.

Dose, ten to thirty minims (0.6–1.8 cc.).

Off. Prep.—Unguentum Hamamelidis, *Br.*

FLUIDEXTRACTUM HYDRASTIS. U. S. (Br.)

FLUIDEXTRACT OF HYDRASTIS Fldext. Hydrast. [Fluidextract of Golden Seal]

"Fluidextract of Hydrastis yields, from each 100 cc., not less than 1.8 Gm. and not more than 2.2 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.* "Liquid Extract of Hydrastis contains in 100 millilitres 2 grammes of hydrastine." *Br.*

Extractum Hydrastis Liquidum, *Br.;* Liquid Extract of Hydrastis; Extrait liquide de Hydrastis, *Fr.;* Extractum Hydrastis fluidum, *P. G.;* Hydrastis-Fluidextrakt; Flüssiges Hydrastisextrakt, *G.;* Estratto di idraste liquido, *It.;* Extracto fluido de hidrastis, *Sp.*

"Hydrastis, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B (page 160), using a mixture of 100 cc. of glycerin, 600 cc. of alcohol, and 200 cc. of water as Menstruum I, and a mixture of 2 volumes of alcohol and 1 volume of water as Menstruum II. Reserve the first 750 cc. of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough of Menstruum II to make each 100 cc. of the finished Fluidextract contain 2 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.*

Assay.—"Proceed by Type Process D, taking 5 cc. of Fluidextract of Hydrastis, using ether as the solvent, and determine the alkaloids gravimetrically (Proximate Assays).

"Alcohol content, by volume, 47 to 52 per cent." *U. S.*

"Determine the proportion of hydrastine in the liquid extract thus obtained by the following process: Transfer 10 millilitres of the liquid extract to a 100 millilitre graduated flask, add 20 millilitres of *solution of potassium iodide* diluted with 60 millilitres of *water,* and then sufficient *water* to produce 100 millilitres. Shake the mixture for several minutes and filter. Transfer 50 millilitres of the filtrate to a separator, render alkaline with *solution of ammonia,* add 30 millilitres of *ether,* and shake at intervals during several minutes. Allow the liquids to separate, draw off the aqueous solution into a beaker and the ethereal solution into a tared beaker. Return the aqueous solution to the separator and repeat the operation with two successive portions, each of 20 millilitres, of *ether* for one minute. Draw off and reject the aqueous layer; transfer the ethereal solutions to the tared beaker and evaporate at a gentle heat; dry the residue on a water-bath and weigh. The weight is that of the hydrastine in 5 millilitres of the liquid extract examined. To the remainder of the liquid extract add sufficient of the menstruum to produce a Liquid Extract of Hydrastis containing 2 grammes of hydrastine in 100 millilitres. Examined by the foregoing process Liquid Extract of Hydrastis is found to contain in 100 millilitres 2 grammes of hydrastine. *Limit of error* 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of hydrastine in 100 millilitres; 110 minims contain 2 grains." *Br.*

The Holland Pharmacopœia Commission have proposed a ratio of alkaloidal matter to total extractive in this preparation of 1 to 8.5.

The fluidextract thoroughly represents the drug. It is of a deep brownish-yellow color.

Dose, from fifteen minims to one fluidrachm (0.9–3.75 cc.).

Off. Prep.—Tinctura Hydrastis, *Br.;* Mistura Rhei Alkalina, *N. F.;* Elixir Hydrastis Compositum, *N. F.*

FLUIDEXTRACTUM HYOSCYAMI. U. S.

FLUIDEXTRACT OF HYOSCYAMUS Fldext. Hyosc. [Fluidextract of Henbane]

"Fluidextract of Hyoscyamus yields, from each 100 cc., not less than 0.055 Gm. and not more than 0.075 Gm. of the alkaloids of hyoscyamus." *U. S.*

Extrait liquide de Jusquiame, *Fr.;* Flüssiges Bilsenkrautextrakt, *G.*

"Hyoscyamus, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 3 volumes of alcohol and 1 volume of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough menstruum to make each 100 cc. of the finished Fluidextract contain 0.065 Gm. of the alkaloids of hyoscyamus.

"**Assay.**—Proceed by Type Process D, taking 25 cc. of Fluidextract of Hyoscyamus, using chloroform as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of hyoscyamus (Proximate Assays).

"Alcohol content, by volume, 58 to 63 per cent." *U. S.*

Dose, from three to ten minims (0.2–0.6 cc.).

FLUIDEXTRACTUM IPECACUANHÆ. U. S. (Br.)

FLUIDEXTRACT OF IPECAC Fldext. Ipecac.

"Fluidextract of Ipecac yields, from each 100 cc., not less than 1.35 Gm. and not more than 1.65 Gm. of the ether-soluble alkaloids of ipecac." *U. S.* "Liquid Extract of Ipecacuanha contains in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root." *Br.*

Extractum Ipecacuanhæ Liquidum, *Br.;* Liquid Extract of Ipecacuanha; Extrait liquide d'Ipécacuanha, *Fr.;* Flüssiges Ipecacuanhaextrakt, *G.*

"Ipecac, in fine powder, 1000 Gm.; Diluted Hydrochloric Acid, a sufficient quantity. Prepare a Fluidextract by Type Process B, using a mixture of 150 cc. of diluted hydrochloric acid, 300 cc. of alcohol, and 300 cc. of water as Menstruum I, and a mixture of 2 volumes of alcohol and 3 volumes of water as Menstruum II. Reserve the first 800 cc. of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained ascertain by calculation the amount of alkaloids in the remainder of the liquid. Test a small portion for miscibility by adding 7 cc. to a mixture of 10 cc. of glycerin and sufficient syrup to make 100 cc. If this does not produce a clear mixture, gradually add diluted hydrochloric acid, drop by drop, until a clear mixture is obtained which will remain clear for four days. Add to the remainder of the Fluidextract the amount of diluted hydrochloric acid determined as necessary by this test and sufficient of Menstruum II to make each 100 cc. of the finished Fluidextract contain 1.5 Gm. of the ether-soluble alkaloids of ipecac." *U. S.*

"Ipecacuanha Root, in No. 120 powder, 1000 *grammes;* Alcohol (90 per cent.), *a sufficient quantity.* Pack the Ipecacuanha Root uniformly in a conical percolator, add two hundred *millilitres* of the Alcohol, and set aside for twelve hours; then percolate with successive portions, each of two hundred *millilitres,* of the Alcohol, added at intervals of twelve hours, until the liquid begins to drop from the orifice of the percolator. Continue the percolation with more of the Alcohol until seven hundred and fifty *millilitres* of percolate have been collected. Reserve this portion. Then percolate until exhaustion is complete; recover the alcohol from this percolate by distillation, and dissolve the residual extract in the reserved portion." *Br.*

The menstruum for the U. S. fluidextract contains hydrochloric acid, which combines with the alkaloids and more thoroughly exhausts the ipecac. It was proved by J. U. Lloyd that when alcohol alone is used a portion of emetine escapes solution. On the other hand, it is known that when the menstruum is more aqueous large amounts of the pectinous principles are taken up, and it is very desirable to separate these in order to prevent their appearance as a flocculent precipitate in syrup of ipecac; but efficiency is to be sought for as the first desideratum, and hence a menstruum which will extract the activity and make a fluidextract that will not let fall a bulky precipitate of inert matter has been secured; usually this will not mix with syrup without slight precipitation, but the improved official process for syrup of ipecac should effectually separate any precipitate resulting from the presence of apotheme in the fluidextract. An *acetic extract of ipecac* (dry) is used in Great Britain; it has been shown that the heating necessary to dry it is injurious to its emetic properties. (*P. J.,* 1895, 158.)

Assay.—"Proceed by Type Process D, taking 5 cc. of Fluidextract of Ipecac, using ether as the solvent, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.024 Gm. of the alkaloids of ipecac (Proximate Assays).

"Alcohol content, by volume, 28 to 33 per cent." *U. S.*

Victor O. Mattson (*D. C.,* 1925, p. 224) points out that while the ipecac assay method of the U. S. P. IX for the root itself gives very satisfactory results, the method of the U. S. P. IX for the assay of the fluidextract of ipecac gives discordant results, probably due to the fact that alkaloidal isomers are formed when the fluidextract is evaporated upon sawdust as directed at or below 80° C. They find that evaporation in a vacuum gives satisfactory results. In the U. S. P. X, the method of assay for ipecac root has not been changed from that of the U. S. P. IX, but the method for the fluidextract has been materially changed in that no evaporation whatever is required, and chances of injury by heat are therefore entirely eliminated.

"Determine the proportion of alkaloids in the liquid extract thus obtained by the following process: Introduce 5 *millilitres* of the liquid extract into a separator and add 4 *millilitres* of *water,* 1 *millilitre* of *diluted sulphuric acid,* and 10 *millilitres* of *ether.* Shake, and separate the ethereal solution. Repeat the shaking with 5 *millilitres* of *ether* and again separate. Wash the mixed ethereal solutions in a second separator with two successive portions, each of 5 *millilitres,* of *water,* and add the washings to the contents of the first separator. Shake this aqueous liquid with 10 *millilitres* of *chloroform* and excess of *solution of ammonia.* Separate the chloroformic solution and filter it through a small filter-paper into a tared dish. Repeat the shaking with *chloroform,* separation, and filtration, twice, finally washing the filter-paper with a little *chloroform.* Evaporate the mixed chloroformic solutions to about 2 *millilitres,* add 5 *millilitres* of *ether,* evaporate, dry at a temperature not exceeding 80° C. and weigh the residual alkaloids. To the remainder of the liquid extract add sufficient of the Alcohol to produce a Liquid Extract of Ipecacuanha containing in 100 *millilitres* 2 grammes of the alkaloids of Ipecacuanha Root. Examined by the foregoing process Liquid Extract of Ipecacuanha is found to contain in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root. *Limit of error* 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of the alkaloids of Ipecacuanha Root in 100 millilitres; 110 minims contains 2 grains." *Br.*

This fluidextract is a thin, dark reddish-

UNIVERSITY OF ILLINOIS
LIBRARY CHEMISTRY

brown, transparent liquid, of a bitterish, slightly acrid taste, but without the nauseous flavor of the root. It is a convenient preparation for adding to expectorant and diaphoretic mixtures.

Dose, as emetic, fifteen to thirty minims (0.9–1.8 cc); as an expectorant, one to two minims (0.06–0.12 cc.).

Off. Prep.—Syrupus Ipecacuanhæ, *U. S.;* Tinctura Ipecacuanhæ et Opii, *N. F.;* Vinum Ipecacuanhæ, *Br.;* Mistura Rhei Composita, *N. F.;* Syrupus Asari Compositus, *N. F.*

EXTRACTUM KAVÆ LIQUIDUM. Br.

LIQUID EXTRACT OF KAVA

"Kava Rhizome, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Alcohol (45 per cent.), *a sufficient quantity.* Mix the powdered Kava Rhizome with two thousand *millilitres* of the Alcohol (90 per cent.); set aside in a closed vessel for forty-eight hours; transfer to a percolator and percolate slowly, reserving the first seven hundred and fifty *millilitres* of the percolate. Continue the percolation, adding the Alcohol (45 per cent.) until the powder is exhausted; recover most of the alcohol from this percolate by distillation; evaporate the residue at a temperature below 80° C. to a soft extract, and dissolve this in the reserved percolate; add sufficient of the Alcohol (90 per cent.) to produce one thousand *millilitres* of the Liquid Extract." *Br.*

This fluidextract is also official in the N. F. (See Part III.)

Dose, thirty minims to one fluidrachm (1.8–3.75 cc.).

EXTRACTUM NUCIS VOMICÆ LIQUIDUM. Br.

FLUIDEXTRACT OF NUX VOMICA Fldext. Nuc. Vom.

"*One hundred cc.* of Fluidextract of Nux Vomica yields not less than 2.37 Gm. nor more than 2.63 Gm. of the alkaloids of nux vomica." *U. S.* "Liquid Extract of Nux Vomica contains in 100 millilitres 1.5 grammes of strychnine." *Br.*

Fluidextractum Nucis Vomicæ, *N. F.;* Fluidextract of Nux Vomica; Extrait liquide de Noix-Vomique, *Fr.;* Flüssiges Kräbenaugen-Extrakt, Brechnussextrakt, Strychnossamenextrakt, *G.*

"Nux Vomica, in No. 20 powder, 1000 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Exhaust the Nux Vomica with the Alcohol by the *repercolation process* until five hundred millilitres of percolate have been obtained. Place this percolate in a closed vessel with fifteen grammes of Hard Paraffin and heat to 60° C. for a few minutes, shaking vigorously. Allow the contents of the vessel to cool and the layer of paraffin which will have separated to solidify. Pour off the percolate thus freed from fat; filter." *Br.*

"Determine the proportion of strychnine in it by the following process: Evaporate 10 *millilitres* on a water-bath to a syrupy extract; dissolve the residue in 10 *millilitres* of warm *water* and transfer to a separator, washing the dish with a further 10 *millilitres* of *water.* Add 10 *millilitres* of *chloroform* and a solution of 5 *grammes* of *sodium carbonate* in 25 *millilitres* of *water.* Shake vigorously; set aside and separate the chloroformic solution. Repeat the extraction with *chloroform* twice. Mix the three chloroformic solutions, and extract the alkaloids by shaking with three successive portions, each of 10 *millilitres,* of *N/1 solution of sulphuric acid,* transferring the acid solutions to a second separator. Make the acid solutions alkaline with *solution of ammonia,* and again extract the alkaloids by shaking successively with 10, 5, and 5 *millilitres* of *chloroform,* drawing off the chloroformic solutions into a small flask. Remove the chloroform by distillation, dissolve the residue in 15 *millilitres* of *water* containing 3 per cent. by weight of *sulphuric acid,* heat the solution to 50° C., add 3 *millilitres* of a mixture of equal volumes of *nitric acid* and *water,* and set aside for ten minutes. Transfer the solution to a separator, rinsing the flask with a little *water,* make alkaline with *solution of sodium hydroxide,* and extract the alkaloid by shaking successively with 10, 5, and 5 *millilitres* of *chloroform.* Wash the mixed chloroformic solutions in a separator with 5 *millilitres* of *water,* transfer to a tared dish and allow the chloroform to evaporate, adding towards the end 5 *millilitres* of *alcohol* (90 per cent.). Evaporate to dryness, dry the residue at 100° C. and weigh. The weight is the weight in *grammes* of the strychnine contained in 10 *millilitres* of percolate. To the remainder of the percolate add sufficient Alcohol (70 per cent.) to produce a Liquid Extract of Nux Vomica containing in 100 *millilitres* 1.5 *grammes* of strychnine. Examined by the foregoing process Liquid Extract of Nux Vomica is found to contain in 100 *millilitres* 1.5 *grammes* of strychnine. *Limit of error* 0.05 *gramme* in excess or defect. This Liquid Extract contains 1.5 grammes of strychnine in 100 *millilitres;* 110 minims contain 1.5 grains." *Br.*

For *Fluidextractum Nucis Vomicæ,* N. F., see Part III.

Dose, one to three minims (0.06–0.2 cc.).

Off. Prep.—Tinctura Nucis Vomicæ, *Br.;* Extractum Nucis Vomicæ Siccum, *Br.*

EXTRACTUM OPII LIQUIDUM. Br.

LIQUID EXTRACT OF OPIUM

"Liquid Extract of Opium contains in 100 millilitres 0.75 gramme of morphine, calculated as anhydrous." *Br.*

"Dry Extract of Opium, 37.5 *grammes;* Alcohol (90 per cent.), 200.0 *millilitres;* Distilled Water sufficient to produce 1000.0 *millilitres.* Mix the Extract with seven hundred *millilitres* of the Distilled Water; set aside in a cool place for twenty-four hours, stirring frequently; add the Alcohol; set aside again for twenty-four hours; filter; wash the filter with sufficient Distilled Water to produce the required volume." *Br.*

"Examined by the process described under 'Tinctura Opii,' Liquid Extract of Opium is found to contain in 100 millilitres 0.75 gramme of morphine, calculated as anhydrous. *Limit of error* 0.05 gramme in excess or defect. This Liquid Extract contains 0.75 gramme of morphine in 100 millilitres; 110 minims contains 3/4 grain." *Br.*

It is well known that in opium there are principles soluble in alcohol but not in water, which often produce various disagreeable effects not experienced from the aqueous extract; what was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of solid extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, but the spirit constitutes only one-fifth, which is considerably short of the proportion recommended by Squire. In the *Deodorized Tincture of Opium* of the U. S. Pharmacopœia the advantages of the preparation have, we think, been still better secured.

Dose, five to thirty minims (0.3–1.8 cc.).

EXTRACTUM PICRORHIZÆ LIQUIDUM. Br.

LIQUID EXTRACT OF PICRORHIZA

"Picrorhiza, in No. 60 powder, 1000 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Picrorhiza with the Alcohol by the *percolation process.* Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This fluidextract was transferred from the British and Colonial Addendum to the British Pharm. (1914). (See *Picrorhiza.*)

Dose, fifteen to sixty minims (0.9–3.75 cc.).

FLUIDEXTRACTUM RHOIS GLABRÆ. U. S.

FLUIDEXTRACT OF RHUS GLABRA Fldext. Rhois. Glab.

Fluidextract of Sumach Berries.

"Rhus Glabra, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B (page 160), using a mixture of 100 cc. of glycerin, 500 cc. of alcohol, and 400 cc. of water as Menstruum I, and diluted alcohol as Menstruum II.

"Alcohol content, by volume, 37 to 43 per cent." *U. S.*

This astringent is most popular as a gargle because of its not unpleasant flavor; it should be diluted with 2 or 3 times its volume of water for this purpose. It is also sometimes employed in diarrhea.

Dose, one to two fluidrachms (4–8 cc.).

FLUIDEXTRACTUM RHEI. U. S.

FLUIDEXTRACT OF RHUBARB Fldext. Rhei

Extrait liquide de Rhubarbe, *Fr.;* Flüssiges Rhabarberextrakt, *G.*

"Rhubarb, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 4 volumes of alcohol and 1 volume of water as the menstruum.

"Alcohol content, by volume, 55 to 63 per cent." *U. S.*

The present process affords a fluidextract which thoroughly represents the root, but when mixed with syrups and water, it loses its transparency. An alkali or an alkaline carbonate dissolves this precipitate, but the use of the fluidextract is limited. The British Pharm. (1898) "Liquor Rhei Concentratus" is made with alcohol (20 per cent.) as a menstruum and is one-half the strength of the U. S. fluidextract of rhubarb.

Dose, for an adult, as a purgative, twenty to thirty minims (1.3–1.8 cc.); as a laxative, from five to ten minims (0.3–0.6 cc.).

Off. Prep.—Syrupus Rhei, *U. S.;* Mistura Rhei Alkalina, *N. F.;* Mistura Rhei Composita, *N. F.;* Elixir Catharticæ Compositum; *N. F.*

FLUIDEXTRACTUM ROSÆ. U. S.

FLUIDEXTRACT OF ROSE Fldext. Rosæ

Fluidextract of Red Rose; Extrait liquide de Rose rouge, *Fr.;* Flüssiges Essigrosenblumenblätterextrakt, *G.*

"Red Rose, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B, using a mixture of 100 cc. of glycerin, 500 cc. of alcohol, and 400 cc. of water as Menstruum I, and diluted alcohol as Menstruum II.

"Alcohol content, by volume, 35 to 40 per cent." *U. S.*

This fluidextract is a useful adjuvant and an excellent astringent. It is of a deep red color, with the agreeable flavor of rose. Wm. C. Alpers prefers repercolation for this fluidextract, stating that even a moderate heat imparts an unpleasant odor to the finished product. (*Proc. A. Ph. A.,* 1897, 425.)

Dose, from one to two fluidrachms (3.75–7.5 cc.).

Off. Prep.—Mel Rosæ, *U. S.;* Syrupus Rosæ, *N. F.*

FLUIDEXTRACTUM SARSAPARILLÆ. U. S.

FLUIDEXTRACT OF SARSAPARILLA Fldext. Sarsap.

Extractum Sarsæ Liquidum, *Br.* 1898; Liquid Extract of Sarsaparilla; Liquor Sarsæ; Extrait liquide de Salsepareille, *Fr.;* Flüssiges Sarsaparillaextrakt, *G.*

"Sarsaparilla, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using diluted alcohol as the menstruum.

"Alcohol content, by volume, 37 to 42 per cent." *U. S.*

Dose, thirty to sixty minims (1.8–3.75 cc.).

Off. Prep.—Syrupus Sarsaparillæ Compositus, *U. S.*

FLUIDEXTRACTUM SCILLÆ. U. S.

FLUIDEXTRACT OF SQUILL Fldext. Scil.

"Fluidextract of Squill, properly diluted and injected into the ventral lymph sac of a frog, has a minimum systolic dose of not less than 0.00,055 cc. and not more than 0.00,065 cc. of Fluidextract, or the equivalent in Fluidextract of not less than 0.00,000,046 Gm. and not more than 0.00,000,054 Gm. of ouabain, for each gram of body weight of frog." *U. S.*

Extrait liquide de Scille, *Fr.;* Flüssiges Meerzwiebelextrakt, *G.*

"Squill, in coarse powder, 1000 Gm.; Diluted Alcohol; Alcohol; Water; each, a sufficient quantity to make about 1000 cc. Mix 2000 cc. of alcohol with 1000 cc. of water, moisten the squill thoroughly with a sufficient quantity of the mixture, and allow it to macerate for two hours in a tightly-covered container. Then transfer to a percolator, shake it down evenly without packing, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum composed of 2 volumes of alcohol and 1 volume of water. When the percolate measures 1000 cc., close the lower orifice, and macerate the drug for twelve hours before continuing the percolation. Then collect a second 1000 cc. of percolate, again interrupt the percolation, macerate for twelve hours, and then continue the percolation until the total percolate measures 5000 cc. Recover the alcohol from the percolate at as low a temperature as possible, and then concentrate the residue to a volume measuring 800 cc. When the residue is cold, add slowly, with continuous agitation, 2000 cc. of alcohol, and set the mixture aside in a tightly-stoppered container for twelve hours. Decant the supernatant liquid from the syrupy layer, filter the decanted liquid, and wash the syrupy residue with two portions of 300 cc. each of a mixture of 4 volumes of alcohol and 1 volume of water, passing the washings through the filter into the previously collected alcoholic liquid. Reduce the combined alcoholic liquids to 800 cc. by distillation, assay a portion as directed below, and from the result thus obtained adjust the volume of the finished Fluidextract by the addition of diluted alcohol to conform to the above biological standard.

"**Assay.**—Proceed as directed under *Scilla.* Alcohol content, by volume, 47 to 52 per cent." *U. S.*

Dose, from one to three minims (0.06–0.2 cc.).

Off. Prep.—Syrupus Scillæ Compositus, *U. S.;* Mistura Pectoralis, Stokes, *N. F.*

FLUIDEXTRACTUM SENEGÆ. U. S.

FLUIDEXTRACT OF SENEGA Fldext. Seneg.

Extrait liquide de Polygale de Virginie, Extrait liquide de Sénéca, *Fr.;* Flüssiges Senegaextrakt, *G.*

"Senega, in moderately coarse powder, 1000 Gm.; Ammonia Water; Alcohol; Water; each, a sufficient quantity to make 1000 cc. Moisten the drug with a sufficient quantity of a mixture of 2 volumes of alcohol and 1 volume of water, pack it in a cylindrical percolator and add more of the menstruum to saturate the drug and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more of the same menstruum until the drug is exhausted. Reserve the first 800 cc. of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and then gradually add ammonia water until the product is faintly alkaline and has a slight odor of ammonia. Finally add enough of the menstruum to make the Fluidextract measure 1000 cc.

"Alcohol content, by volume, 45 to 50 per cent." *U. S.*

Formerly, Fluidextract of Senega was very frequently the cause of annoyance to the pharmacist through gelatinization. This was due to the presence of pectinous bodies in the root. The addition of an alkali to the menstruum effectually prevents this, and in this respect the present preparation is a great improvement over the 1890 fluidextract.

For other processes, see *N. R.,* 1883, pp. 195, 196. The British Pharm. (1898) "Liquor Senegæ Concentratus" was made half the strength of the U. S. fluidextract with a menstruum composed of 2 parts of 20 per cent. alcohol and 1 part of 45 per cent. alcohol.

Dose, five to twenty minims (0.3–1.3 cc.).

Off. Prep.—Syrupus Scillæ Compositus, *U. S.;* Syrupus Senegæ, *U. S.;* Mistura Pectoralis, Stokes, *N. F.;* Syrupus Cimicifugæ Compositus, *N. F.*

FLUIDEXTRACTUM SENNÆ. U. S.

FLUIDEXTRACT OF SENNA Fldext. Senn.

Extrait liquide de Séné, *Fr.;* Flüssiges Sennaextrakt, *G.*

"Senna, in coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using a mixture of 1 volume of alcohol and 2 volumes of water as the menstruum, and reserving the first 800 cc. of percolate.

"Alcohol content, by volume, 23 to 27 per cent." *U. S.*

The U. S. P. VIII process provided for the elimination of the griping principles by the previous percolation of the powdered senna with alcohol; diluted alcohol was then used to exhaust the drug of the purgative principles.

This previous treatment of the senna is omitted from the U. S. P. X process and the menstruum was made less alcoholic. The fluidextract is a dark, blackish, thick, and somewhat turbid liquid, with a strong flavor of senna. It is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluidextract should be given at once.

The British Pharm. (1898) "Liquor Sennæ Concentratus" was more like a concentrated infusion than a fluidextract, but had the same strength of the latter, the menstruum is distilled water; tincture of ginger and alcohol being added.

Dose, from one-half to two fluidrachms (1.8–7.5 cc.), for an adult.

Off. Prep.—Syrupus Sennæ, *U. S.;* Elixir Cascaræ Compositum, *N. F.;* Elixir Catharticum Compositum, *N. F.;* Syrupus Ficorum Compositus, *N. F.;* Syrupus Sennæ Aromaticus, *N. F.*

FLUIDEXTRACTUM UVÆ URSI. U. S.

FLUIDEXTRACT OF UVA URSI Fldext. Uvæ Ursi

Extrait liquide de Busserole, *Fr.;* Flüssiges Bärentraubenblätterextrakt, *G.*

"Uva Ursi, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process B, using a mixture of 100 cc. of glycerin, 300 cc. of alcohol, and 500 cc. of water as Menstruum I, and a mixture of 1 volume of alcohol and 2 volumes of water as Menstruum II. Reserve the first 800 cc. of percolate.

"Alcohol content, by volume, 18 to 25 per cent." *U. S.*

This preparation is a dense, almost black, liquid, of a sweet, bitterish, astringent, but not very disagreeable taste.

Dose, from thirty minims to a fluidrachm (1.8–3.75 cc.).

EXTRACTUM VIBURNI PRUNIFOLII LIQUIDUM. Br.

LIQUID EXTRACT OF BLACK HAW

Fluidextractum Viburni Prunifolii, *U. S. IX;* Fluidextract of Viburnum Prunifolium; Black Haw; Extrait liquide de Viburne, *Fr.;* Flüssiges Viburnumextrakt, *G.*

"Black Haw, in No. 60 powder, 1000 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Black Haw with the Alcohol by the *percolation process.* Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This is a fluidextract which well represents the drug. It is of a dark reddish-brown color.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

FLUIDEXTRACTUM ZINGIBERIS. U. S.

FLUIDEXTRACT OF GINGER Fldext. Zingib.

Extrait liquide de Gingembre, *Fr.;* Flüssiges Ingwerextrakt, *G.*

"Ginger, in moderately coarse powder, 1000 Gm. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum.

"Alcohol content, by volume, 78 to 83 per cent." *U. S.*

This fluidextract is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish color.

Dose, from five to fifteen minims (0.3–1.0 cc.).

Off. Prep.—Syrupus Zingiberis, *U. S.;* Elixir Hydrastis Compositum, *N. F.*

FŒNICULUM. N. F. (Br.)

FENNEL Fœnic. [Fennel Seed]

"Fennell is the dried, ripe fruit of cultivated varieties of *Foeniculum vulgare* Miller (Fam. *Umbelliferæ*). Fennel contains not more than 4 per cent. of foreign organic matter." *N. F.*

"Fennel Fruit is the ripe fruit of Fœniculum vulgare, *Mill.*, collected from cultivated plants, and dried." *Br.*

Fœniculi Fructus, *Br.;* Semen Fœniculi, Fennel Fruit (Seed), Sweet Fennel Fruit; Fenouil doux (Fruit), *Fr. Cod.;* Fruits (Semences) de Fenouil, *Fr.;* Fructus Fœniculi, *P. G.;* Fenchel, Fenchelsamen, *G.;* Finocchio, *It.;* Hinojo, *Sp.*

The plant producing fennel seed was attached by Linnæus to the genus *Anethum,* but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled *Fœniculum,* which has been generally adopted by botanists. The *Anethum Fœniculum* of Linnæus embraced two varieties, the *common* or *wild fennel,* and the *sweet fennel,* the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively *Fœniculum vulgare* and *Fœniculum dulce,* but the correctness of the opinion of the great Swedish botanist is now generally admitted.

Fœniculum vulgare is a stout, glabrous biennial or perennial, aromatic herb 3 to 5 feet tall with pinnately decompound leaves having numerous filiform terminal segments. The small yellow flowers are in large, flat, terminal compound umbels, with from thirteen to twenty rays, and destitute both of general and partial involucres. The corolla consists of five petals, which, as well as the stamens, are golden yellow. The fruit is ovate, and of a dark color, especially in the grooves. The plant is a native of Southern Europe, growing wild upon sandy and chalky ground throughout the continent, and is also abundant in Asia, possibly extending as far as China. It is extensively cultivated in Europe as well as in this country. It has escaped from gardens and is somewhat naturalized in Maryland and Virginia. In India, fennel is said to be obtained from *F. panmorium* DC., which is probably, however, only a variety of the official plant. Sicilian fennel or *Carosella* is the fruit of *F. piperitum* DC. (*F. vulgare* var. *piperitum* Hart.). Its young tender stems enclosed in the sheathing leaf stalks are eaten raw by the natives of Southern Italy and Sicily.

F. dulce De Cand., *Sweet Fennel,* bears a general resemblance to *F. vulgare,* but differs in having its stem somewhat compressed at the base, its radical leaves somewhat distichous, and the number of rays in the umbel only from 6 to 8. It is also a much smaller plant, being only about a foot high; its flowers appear earlier, and its young sweet shoots, or turions, are eaten in Italy boiled or as a salad.

Most of our supply comes from Hamburg, Germany, although Leghorn, Italy and Marseilles, France were also important shipping centers. The drug is imported in bags. German fennel is shipped mostly from Hamburg, Roumanian fennel from Hamburg and Trieste, French fennel mostly from Marseilles, Levant fennel from Trieste, Indian fennel from Bombay and London. The German large fennel is green in color and is the variety usually preferred. The French, Levant, Italian and Indian fennels are yellow. The Roumanian variety is small and green and not highly prized.

The roots of fennel were formerly employed in medicine, but are generally inferior in virtues to the fruit, which is now the only portion recognized by any of the pharmacopœias. It is stated that manufacturers of the oil usually distil the whole plant.

Description and Physical Properties.—"*Unground Fennel.*—Mericarps usually separate, each being broadly elliptical with the commissural surface flattened, more or less curved, from 4 to 15 mm. in length and from 1 to 3.5 mm. in breadth, some having a slender stalk from 2 to 10 mm. in length; dorsal surface convex, yellowish green to grayish brown, with five prominent longitudinal primary ribs and at the summit a short, conical stylopodium; commissural surface with three narrow, light brown longitudinal areas separated by two dark brown or brownish black areas containing oil-tubes. Odor and taste aromatic and characteristic.

"*Structure.*—A pentagonal mericarp, four of the sides being nearly equal and slightly concave, the other or commissural surface being much broader and more or less undulate; cells of the seed-coat closely united with those of the mericarp giving the transverse section two very distinct areas, the inner and larger portion (endosperm) more or less rounded-pentagonal and somewhat reniform, composed of polygonal cells, filled with aleurone grains and a thin protoplasmic layer enclosing a fixed oil; the outer or pericarp layer distinguished by large elliptical oil-tubes with thick, brown walls, the latter occurring singly and alternating with the primary ribs, and two oil-tubes on the dorsal surface, making usually six oil-tubes in all, there sometimes being, however, one or two oil-tubes additional; in the central portion of each of the ribs occurs a nearly circular, fibro-vascular bundle with a few tracheæ and numerous thin-walled, strongly lignified fibers.

"*Powdered Fennel.*—Yellowish brown; colorless, irregular, angular fragments of endosperm, the cells filled with aleurone grains, each containing a rosette of calcium oxalate, 0.002 mm. to 0.005 mm. in diameter; fragments containing yellowish brown oil-tubes, the latter from 0.100 to 0.200 mm. in width; fibers few, strongly lignified and with numerous, oblique, simple pores and occasionally reticulately thickened; tracheæ few, with spiral or annular thickenings; in mounts made with chloral hydrate T.S., numerous globules of a fixed oil separate." *N. F.*

Fennel seeds (half fruits) are officially described in the Br. Pharm. as follows:

"Small, oblong, straight or slightly curved, from three to ten millimetres long, and from two to four millimetres in diameter. Greenish or greenish-brown. Each of the two mericarps with five prominent principal ridges and six large vittæ. Aromatic odor; taste strong, sweet and camphoraceous. Ash not more than 11 per cent." *Br.*

There are ten chief varieties of fennel known in commerce, the fruits differing very much in size and considerably in taste. They are as follows: French (sweet); French (bitter); German; Roumanian; Indian; Russian; Levant; Italian; Persian and Japanese. For histological differences of the different commercial varieties see monograph by Hartwich and Jama in *B. P. G.*, 1909, p. 306. Rosenthaler (*B. P. G.*, 1913, p. 570) has made a pharmacognostical study of a Chinese fennel.

Commercial fennel varies greatly in quality, this being either due to lack of care in harvesting or deliberate adulteration. It may contain sand, dirt, stem tissues, weed seeds, or other material to an extent that amounts to adulteration. The fruits, especially the powder, may be deficient in volatile oil, inferring that they have been partly exhausted. Exhausted or otherwise inferior fennel has been occasionally improved in appearance by the use of a factitious coloring. (See Spaeth, in *Ph. Zentralh.*, 1908, p. 545; and 1913, p. 736.) Bitter fennel (*F. piperitum*) has in some instances been substituted for the true article. It may be distinguished from the latter by its smaller size and bitter taste.

The odor of fennel seed is fragrant, its taste warm, sweet, and agreeably aromatic. It yields its virtues to hot water, but more freely to alcohol. The essential oil may be separated by distillation with water. (See *Oleum Fœniculi.*) From 960 parts of the seed Neumann obtained 20 parts of volatile and 120 of fixed oil.

Uses.—Fennel seed was used by the ancients. It is one of our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicine, particularly senna and rhubarb. It is recommended for these purposes by the absence of any highly excitant property. An infusion may be prepared by introducing two or three drachms of the seeds into a pint of boiling water. In infants the infusion is frequently employed as an enema for the expulsion of flatus.

Dose, of the bruised or powdered seeds, twenty grains to half a drachm (1.3–2.0 Gm.).

Off. Prep.—Aqua Fœniculi, *U. S.* (from Oil), *Br.;* Infusum Sennæ Compositum, *N. F.;* Pulvis Glycyrrhizæ Compositus, *Br.;* Pilulæ Antiperiodicæ, *N. F.;* Pilulæ Antiperiodicæ sine Aloes, *N. F.;* Species Laxativæ, *N. F.;* Tinctura Antiperiodica, *N. F.;* Tinctura Antiperiodica sine Aloe, *N. F.*

FRANGULA. N. F.

FRANGULA Frang. [Buckthorn Bark]

"Frangula is the dried bark of *Rhamnus Frangula* Linné (Fam. *Rhamnaceæ*). Frangula contains not more than 2 per cent. of foreign organic matter." *N. F.*

Rhamni Frangulæ Cortex, *Br.* (1865); Frangula Bark; Alder Buckthorn; Ecorce de Bourdaine, Bourgène, *Fr.;* Cortex Frangulæ, *P. G.;* Faulbaumrinde, *G.;* Corteccia di frangola, *It.*

R. Frangula or *Alder Buckthorn* is an erect glabrous shrub from ten to fifteen feet high, without thorns, with broadly ovate, obtuse leaves, the margins being entire or slightly sinuate, the underside sometimes slightly downy, and the rather numerous lateral veins diverging equally almost from the whole length of the midrib. Flowers all hermaphrodite, two or three together in each axil, with the calyx teeth, petals, and stamens in fives. Fruit a dark purple drupe the size of a pea. This plant grows in hedges and bushy places throughout Europe and Russian Asia, except in the far north. It has become established on Long Island, northern New Jersey and in Ontario.

Frangula is collected in the spring and either heated at 37.7° C. for 48 hours or kept one year before being used, so as to render inert the ferment present in the green bark which is claimed to act as a gastro-intestinal irritant. It is packed in bags or bales averaging 100 to 200 lbs. and shipped to this country mainly from Hamburg and Trieste.

It is probable that most of the species of the genus *Rhamnus* have cathartic properties. Articles upon *R. Purshiana* and *R. cathartica* will be found elsewhere. (See *Cascara Sagrada* and *Rhamnus Cathartica.*)

Description and Physical Properties.—"*Unground Frangula.*—In quills varying in length, frequently flattened or crushed; from 0.5 to 1 mm. in thickness; outer surface grayish brown or purplish black, with numerous, prominent, lighter-colored, transverse lenticels and occasional patches of foliaceous lichens bearing small, blackish apothecia; inner surface smooth, orange-brown to dark brown with occasional purplish blotches, longitudinally striate, becoming red when moistened with solutions of the alkalies; fracture short, slightly fibrous in the inner layer. Odor distinctive; taste slightly bitter.

"*Structure.*—Corky layer of about 12 rows, distinctly undulate, the cells containing a reddish brown amorphous content; parenchyma cells of the middle bark, small with numerous rosettes of calcium oxalate and small starch grains; a few partially lignified fibers in the middle bark; inner bark with small groups of bast fibers in narrow tangential rows interrupted by the medullary rays, the latter one to three cells in width and containing starch grains; each group of bast fibers surrounded by a layer of crystal fibers.

"*Powdered Frangula.*—Yellowish brown; numerous fragments of cork tissue; fragments of parenchyma tissue, the cells containing rosettes of calcium oxalate, the latter from 0.010 to 0.025 mm. in diameter; bast fibers with thick yellowish, strongly lignified walls, mostly 0.010 to 0.020 mm. in diameter, a few slightly lignified and up to 0.040 mm. in diameter; crystal fibers with prismatic crystals of calcium oxalate, the latter from 0.007 to 0.015 mm. in length; starch grains from 0.003 to 0.010 mm. in diameter; stone cells absent (distinction from *Rhamnus Purshiana*).

"Add 0.1 Gm. of powdered Frangula to 10 cc. of hot distilled water, shake the mixture occasionally until cold and filter; on the addition of a few drops of ammonia water, the filtrate is colored deep red. Macerate 0.1 Gm. of powdered Frangula with 10 drops of alcohol, boil with 10 cc. of distilled water and filter when cold. Shake this filtrate with 10 cc. of ether; a yellow, ethereal solution separates, and 3 cc. of this ethereal solution, when shaken with 3 cc. of ammonia water, yields a red alkaline solution, which, on being diluted with 20 cc. of distilled water, still possesses a distinct cherry-red color." *N. F.*

As first pointed out by Schrenk (*Am. Drug.,* April, 1887), the bark of *Rhamnus Frangula* can be distinguished from that of *R. Purshiana* (*Cascara Sagrada*) by the absence of the irregular angular sclerenchymatous cells, which in *R. Purshiana* are wedged together in large compact groups, increasing in size and number towards the surface, and causing the short fracture of the outer bark.

Tschirch and Pool (*S. W. P.,* 1908, p. 665) have made a comparative pharmacognostical and chemical study of the barks of *R. Frangula* and *R. Purshiana.* Würffel (*Zeit. Oest. Apoth. Ver.,* 1907, p. 211) and Mitlacher (*Bull. sc. pharmacol.,* 1911, p. 10) report the substitution of Frangula by the bark of an alder (*Alnus glutinosa* Medic). The latter may be detected by not being reddened with solutions of the alkalies. Mitlacher (*Ph. Post,* 1905, p. 751) and Moser (*A. J. P.,* 1909, p. 580) have found that the official Frangula is either admixed with or entirely substituted by the bark of *R. carniolica* A. Kerw. Tunmann (*Ph. Era,* 1916, xlix, 113) has also reported on these substitutions. He states that the *R. carniolica* possesses similar constituents to Frangula and gives the important structural differences between the three barks. E'we (*Proc. A. Ph. A.,* 1914, p. 131) obtained a sample of Frangula which proved to be wild-cherry bark.

It is not certainly known which of the several bodies isolated from frangula bark is the purgative principle. The most important body, *frangulin,* the *rhamnoxanthin* ($C_{20}H_{20}O_{10}$) of Buchner and Binswanger, may be obtained by Phipson's process by macerating the bark for three or four days in carbon disulphide, then permitting the liquid to evaporate, exhausting the residue with alcohol, which leaves the fatty matter behind, evaporating the alcoholic liquid to dryness, and recrystallizing from ether. As thus obtained it is in fine yellow crystals, melting at about 229° C., and subliming in golden-yellow needles. It is insoluble in water, soluble in 160 parts of warm 80 per cent. alcohol, nearly insoluble in cold alcohol, soluble in hot fixed oils, petroleum benzin, and oil of turpentine. It communicates its color to cotton, silk, and wool. Faust (*A. Pharm.,* clxxxvii, 8) first proved the glucosidal character of frangulin by boiling it in alcoholic solution with hydrochloric acid, obtaining glucose and *frangulinic acid,* $C_{14}H_8O_4$ (according to Schwabe, $C_{21}H_{20}O_9$). This forms fine microscopic needles of reddish color, fusing at 248° to 250° C. Liebermann and Waldheim (*B. Chem. G.,* ix, p. 1775) obtained in this decomposition instead of frangulinic acid, emodin, which is a trioxymethyl—anthraquinone (see under *Rheum*); frangulinic acid, on the other hand, would be a dioxyanthraquinone and an isomer of alizarin. Gunton and Biehl (*J. A. Ph. A.,* 1922, xi, 669) have also found that emodin and rhamnose were the decomposition products of frangulin; they state that neither frangulin nor emodin are as actively cathartic as the crude drug. They also report the presence of free emodin and of chrysophanol both free and combined.

E. Amweg has devised a method of separating the glucosides from frangula, cascara and rhubarb by extraction with solvents; he uses, 1, benzene; 2, a mixture of two parts of benzene, and one part of absolute alcohol, and 3, alcohol (60 per cent.). (*Ap. Ztg.,* 1897, 747.) Kubly isolated a crude acid which, when purified, he termed *frangulic acid;* Amweg regards this acid as a decomposition product and calls it *pseudofrangulin,* this when hydrolyzed becomes *pseudoemodin.* The emetic action of green bark is attributed to a hydrolytic ferment, which is destroyed by heating. (*P. J.,* 1898, 24.)

Uses.—In its fresh state this drug is very irritant to the gastro-intestinal mucous membrane, producing, when taken in sufficient quantity, violent catharsis, accompanied by vomiting and much pain. During drying it is said to lose much of its irritant power, and the dried bark is affirmed to resemble rhubarb in its action.

Dose, of frangula, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Frangulæ, *N. F.;* Elixir Catharticum Compositum (from Fluidextract), *N. F.*

FUCUS. N. F.

FUCUS [Bladderwrack]

"Fucus is the dried thallus of *Fucus vesiculosus* Linné, *Fucus serratus* Linné, *Fucus Nodosus* Linné or *Fucus siliquosus* Linné (Fam. *Fucaceæ*). Fucus contains not more than 3 per cent. of foreign organic matter and yields not more than 4 per cent. of acid-insoluble ash." *N. F.*

Sea-wrack; Kelp-ware; Black-tang; Cutweed; Quercus Marina; Fucus (Varech) vésiculeux, *Fr.;* Blasentang, Seetang, Meeriche, *G.*

This is a common brown alga of the Rockweed group found growing on the rocks in the North Atlantic Ocean or on the banks of inlets and bays thereof, between low and high tide marks. It attaches itself to the rocks or mussels by its expanded foot. On the coasts of Scotland and France it is much used in the preparations of kelp. It is also employed as a manure, and is mixed with the fodder of cattle.

Under the name of *Corsican moss* or *helminthochorton* there was formerly used, as a vermifuge, a mixture of various marine plants.

Bladder-wrack contains a gelatinous substance known as *algin* (*alginic acid*), about 0.1 per cent. of a volatile oil and a small quantity of combined iodine. According to Marchand (*P. J.,* 1884, p. 1011), the proportion of iodine is much smaller than that in various other seaweeds. It is said to contain mannitol in appreciable amounts. Tollens and Rovoir state that 0.8 per cent. of a sugar named *fucose,* $C_6H_{12}O_6$, exists in dried seaweed. Votocek and Potmesil obtained from fucose an alcohol which they named *fucitol.* (*B. P. G.,* 1913, 3653.)

Description and Physical Properties.—"*Unground Fucus.*—Sometimes a meter in length, but usually in shorter pieces, dichotomously branched, brownish black or slightly reddish, usually with a slight, whitish incrustation; flat, smooth, from 0.5 to 4 cm. in width, margin entire or serrate, with or without a stout midrib throughout, along which are irregularly disposed oval or oblong air-vesicles of varying length or which may be absent; apex of thallus occasionally swollen, ovate or elliptical, about 5 mm. in diameter and bearing numerous conceptacles. Odor strongly seaweed-like; taste saline and nauseous.

"*Structure.*—Epidermal cells polygonal in surface view, with colorless walls; hypodermis of about 4 rows of longitudinally elongated mucilaginous cells; remaining tissue consisting of pseudo-parenchyma loosely arranged, much elongated and with large intercellular spaces; sections bearing conceptacles of thallus show spherical cavities up to about 0.625 mm. in diameter, containing either antheriodiophores bearing pyriform antheridia from 0.030 to 0.043 mm. in length and sterile cells, or rounded oogonia up to 0.080 mm. in diameter separated by paraphyses.

"*Powdered Fucus.*—Reddish brown; numerous fragments of epidermal tissue with polygonal cells from 0.012 to 0.025 mm. in length; elongated cells of hypodermis from 0.045 to 0.080 mm. in length, inner tissue in irregular fragments composed of pseudo-parenchyma with thick mucilaginous walls." *N. F.*

Uses.—The charcoal derived from kelp was at one time used, under the name of *Æthiops vegetabilis* or *vegetable ethiops,* in the treatment of *goiter* and *scrofulous swellings.* Bladderwrack is an ingredient in certain nostrums used in the treatment of morbid *obesity.* A. T. Carson affirms, however, that the *Fucus vesiculosus* is largely used in Ireland for fattening pigs, and it is doubtful whether its preparations are capable of reducing human obesity unless given in such doses as to interfere with digestion and injure the health. A possible explanation of the action of bladderwrack in obesity, if it exercise any, is found in the experiments of Hunt and Seidell (*J. P. Ex. T.,* 1910, ii, p. 15), who present evidence indicating that the extract of this plant is a powerful stimulant to the thyroid gland.

Dose, ten to thirty grains (0.6–2 Gm.).

Off. Prep.—Fluidextractum Fuci, *N. F.*

GALANGA. N. F.

GALANGAL. Galang.

"Galangal is the dried rhizome of *Alpinia officinarum* Hance (Fam. *Zingiberaceæ*). Galangal contains not more than 2 per cent. of foreign organic matter and yields not more than 3 per cent. of acid-insoluble ash." *N. F.*

Chinese Ginger; China Root; India Root; Galangal; East India Catarrh Root; Rhizoma Galangæ, *P. G.;* Galgant, *G.*

The Galangas are related both botanically and therapeutically to ginger. Two varieties are described by authors, the *Galanga major* and *Galanga minor,* or *large* and *small galangal.* The large galangal is derived from *Alpinia Galanga* Willd. (*Maranta Galanga* L., *Galanga officinalis* Salisb.). The official drug, the smaller galangal, is the product of a distinct but closely allied plant, *Alpinia officinarum* Hance. This is a reed-like plant growing to a height of about 3 feet, a native of the Island of Hainan off the southern coast of China, where it is also widely cultivated. The rhizome is dug up in the fall, washed, cut into pieces and dried. Galangal has recently been shipped to the United States in burlap bags from Hamburg, Marseilles and London.

Description and Physical Properties.—"*Unground Galangal.*—Irregularly branched, from 2 to 10 cm. long and from 1 to 2 cm. thick, the branches thinner toward the base; marked with the fine annuli of the leaf bases, which are from 3 to 10 mm. apart and of lighter color than the general surface; externally reddish or rusty-brown; internally of a lighter orange-brown; cut ends of the branches circular and expanded; fracture fibrous. Odor aromatic and agreeable; taste hot and spicy, resembling ginger.

"*Structure.*—An epidermis of cells polygonal in surface view, with thin, nearly colorless walls, some of the cells containing a reddish brown amorphous substance; a wide cortical area composed chiefly of nearly isodiametric, starch-bearing parenchyma and many scattered oil and resin secretion cells, the latter with a yellowish or reddish brown amorphous content; a distinct, narrow endodermis of thin-walled cells, enclosing parenchyma and secretion cells similar to those of the cortex; concentric fibro-vascular bundles numerous, many collateral fibro-vascular bundles throughout the parenchyma and especially along the endodermis.

"*Powdered Galangal.*—Reddish brown; numerous simple starch grains from 0.010 to 0.060 mm. in length, the small grains few in number, the large grains narrow-ellipsoidal, often broadened at one end, truncate, frequently curved, occasionally with a lateral development, lamellæ mostly indistinct, hilum circular or a cleft in the larger end of the grain, sometimes inconspicuous; numerous yellowish oil cells and reddish resin cells; fragments of tracheæ with scalariform or reticulate thickenings or simple pores; thick-walled fibers with oblique pores; lignified tissue absent." *N. F.*

It contains a pungent oil-like principle, *galangol,* a tasteless concrete resin, *kaempferid, galangin* (*dioxyflavanol*) and a small quantity of cineol. The substance called *alpinin* appears to be a mixture of kaempferid and galangin.

Uses.—Galangal is a stimulant aromatic similar in its effects to ginger. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compounds. (*A. J. P.,* xliii.)

Dose, from fifteen to thirty grains (1.0–2.0 Gm.) in substance, and twice as much in infusion.

Off. Prep.—Tinctura Aromatica, *N. F.*

GALEGA. N. F.

GALEGA. Galeg. [European Goat's Rue]

"Galega is the dried flowering herb, *Galega officinalis* Linné (Fam. *Leguminosæ*). Galega contains no stems over 4 mm. in diameter and not more than 3 per cent. of foreign organic matter." *N. F.*

Goat's Rue; Herba Rutæ Caprariæ; Rue de Chèvre, *Fr.;* Geisraute, Pestilenzkraut, *G.*

This is a hardy, bushy, perennial, leguminous herb indigenous to southern Europe and western Asia. It grows to the height of 2 to 3 feet and possesses odd-pinnate leaves with lanceolate leaflets and axillary racemes of small, pea-shaped flowers which vary from purplish-blue in the pure species, to white, rose-colored and lilac in the several varieties. It is native to the south of Europe, and sometimes cultivated in gardens. It is without odor unless bruised, when it emits a disagreeable odor. The crude drug is shipped to this country in burlap bags and bundles chiefly from Leghorn and Marseilles.

Description and Physical Properties.—"*Unground Galega.*—Stem smooth, erect, branched, when entire from 15 to 45 cm. long commonly cut and broken; leaves oddly-pinnate with from 6 to 8 pairs of leaflets; stipules lanceolate, sagittate on one side; leaflets bright green, smooth or slightly hairy, short petioled, lanceolate or ovate-lanceolate, obtuse, slightly mucronate, from 2 to 5 cm. long and from 2 to 6 mm. in width; flowers small, white to violet, in axillary racemes. Odor indistinct; taste mucilaginous, slightly bitter and astringent; it colors the saliva yellowish green.

"*Powdered Galega.*—Light green to yellowish green; many fragments of epidermal tissue of leaf and stem showing narrowly elliptical stomata up to 0.045 mm. in length; numerous somewhat curved or slightly undulate, simple, thick-walled, non-glandular hairs up to 0.600 mm. in length and about 0.018 mm. in diameter at the base; tracheæ with bordered pores, spiral or reticulate markings; numerous crystal fibers with monoclinic prisms of calcium oxalate, the latter from 0.010 to 0.025 mm. in length; numerous fibers with thick, strongly lignified walls and simple pores; fragments of cortical tissue with nearly isodiametric parenchyma, the latter occasionally containing prisms of calcium oxalate; pollen grains smooth spheroidal, from 0.015 to 0.020 mm. in diameter; starch grains somewhat rounded, few or wanting." *N. F.*

It contains a bitter principle and tannin. In 1914 Tanret separated from goat's rue an alkaloid *galegine*, $C_6H_{13}N_3$, which has been further studied by Barger and White (*Bio. Chem. J.*, 1923, xvii, p. 827). They showed it to be a derivative of glycocyanamine.

In medieval times goat's rue was used against the *plague* and other malignant fevers and in the treatment of *snake-bites*, etc. In 1873 Gillet-Damitte, in a communication to the French Academy, stated that this plant when fed to cows would increase the secretion of milk from 35 to 50 per cent.; since that time it has been employed as a galactague with more or less favorable results. Lewis and Carlson (*J. A. M. A.*, 1917, lxviii, 1570) as the result of experimentation on dogs and goats reached the conclusion that it had no effect on the secretion of milk. The root of the indigenous *Tephrosia virginiana* (L.) Pers. (*Galega virginiana* L.) is said to be diaphoretic and anthelmintic.

Dose, one drachm (4 Gm.).

Off. Prep.—Fluidextractum Galegae, *N. F.*

GALLA. U. S., Br.

NUTGALL. Gall.

"Nutgall is the gall from the young twigs of *Quercus infectoria* Olivier and other allied species of *Quercus* (Fam. *Fagaceæ*)." *U. S.* "Galls are excrescences on Quercus infectoria, *Olivier*, resulting from the deposition of the eggs of Cynips gallæ tinctoriæ, *Olivier*." *Br.*

Galls, Aleppo Galls, Smyrna Galls, Syrian Galls; Galla Tinctoria; Galla Quercina; Galle d'Alep, *Fr. Cod.;* Noix de Galle, *Fr.;* Gallæ, *P. G.;* Galläpfel, Gallen, *G.;* Noce di galla, *It.;* Agalla, *Sp.*

Most of the plant outgrowths or excrescences which are known as "galls" are occasioned through the agency of insects. Many of the smaller galls are caused by mites and a few are due to invasion by nematodes and fungi. It is now known that in the case of insect-produced galls two factors are essential to gall formation, *i.e.*, the deposition of an egg in or on a plant tissue capable of growth, and the response of the plant protoplasm to the stimulating action of a secretion exuded by the insect larva. Among insects, the gall-flies belonging to the genus *Cynips* (Fam. *Cynipidæ*, Order *Hymenoptera*) take leading rank as gall-makers. Many of the oaks are attacked by them and the resulting galls, possessing in high degree the astringent constituents of these plants, have been employed for various practical purposes. Galls may occur anywhere on a plant and their form is usually characteristic for each pair of biological agents involved. According to Olivier, the official article is produced mainly on *Quercus infectoria.*

Quercus infectoria, or the so-called *dyer's oak*, is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are petiolate, obtusely toothed, smooth and of a bright-green color on both sides. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy and scaly. This species of *Quercus* grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. M. Kinnier found it also in Armenia and Kurdistan; Hardwicke observed it growing in the neighborhood of Adwanie, and it probably pervades the middle latitudes of Asia.

The gall originates from the deposited egg of the *Cynips tinctoria* Olivier, a hymenopterous insect or fly, with a fawn-colored body, dark antennæ, and the upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound.

It was formerly believed that the tissues of the plant were irritated and their cells caused to proliferate through the puncture produced by the insect's ovipositor, but A. Cosens has thrown new light upon this subject which seems to disprove that theory. It now appears that the larva or young insect, after hatching from the egg, secretes a fluid (probably from its salivary glands) which contains an enzyme that changes the starch in the cells immediately surrounding it into sugar. By increasing the rate of change from starch to sugar, it makes more food available than usual to the growing cells and therefore stimulates the activity of the protoplasm toward greater cell-division. Accordingly, the gall as well as the larva withdraws food from the nutritive zone. As the starch disappears from the cells at the center of the tumor, shrinkage of the cells of this area takes place, resulting in a central cavity. The insect therein passes through the larval and pupal stages and finally, upon becoming an imago or adult fly, escapes by eating its way out, leaving a tubular canal communicating with the central cavity. At the time of development of the adult fly, most of the cells of the gall contain masses of tannin together with a small amount of gallic acid; they are then in the best condition for collection. When collected at this time, they are called, from their dark color, *blue, green* or *black galls.* If gathered after the imago has escaped, the galls are lighter in weight and color, more spongy in texture, and, since the tannin has undergone oxidation to form a water-insoluble product, are practically worthless. Such galls are called *white galls.*

Most of the official galls are collected by the peasants of Asia Minor and Persia, who pursue no systematic method in gathering them. They are then dried in the sun and lose about 50 per cent. in weight. After drying, the product is sold to dealers in the small villages or is bartered for articles of European manufacture. Owing to different degrees of maturity, the galls range in color from black, through green, to white. The black galls contain the greatest amount of tannin and the white contain the smallest quantity. The galls are graded by the exporter. They are exported mainly through Aleppo and Smyrna to Trieste, London, and the United States.

Description and Physical Properties.—"*Unground Nutgall.*—Nearly globular, from 0.8 to 2.5 cm. in diameter, heavy, mostly sinking in water; externally dark olive-green to dark grayish, tuberculated on upper portion; basal portion smooth and contracted into a short stalk; fracture short, horny; internally grayish to dark brown, with a central slightly radiate portion; occasionally with a central cavity connected by a narrow, radial canal to the external surface; odor slight; taste strongly and persistently astringent.

"*Structure.*—The external and largest part of the gall consists of thin-walled parenchyma cells, containing masses of tannin and occasionally rosettes and prisms of calcium oxalate; a middle layer of thick-walled stone cells and an inner layer of thick-walled parenchyma containing starch granules.

"*Powdered Nutgall.*—Brownish-yellow; showing numerous simple and compound starch grains, the simple grains up to 0.030 mm. in size and ellipsoidal, spheroidal, or polygonal in shape; few stone cells with narrow cavities and branched pore-canals; occasionally fragments of spiral and reticulate tracheæ; tannin masses, slowly dissolving in water mounts; monoclinic prisms and rosettes of calcium oxalate, the latter up to 0.040 mm. in diameter." *U. S.*

"Hard, heavy, subglobular, from twelve to eighteen millimeters or more in diameter, tuberculated on the surface, the tubercles and intervening spaces being smooth; dark bluish-green or dark olive-green externally, yellowish or brownish-white within, with a small central cavity. Galls sink in water and exhibit no perforation. No odor; taste intensely astringent." *Br.*

The best are externally of a dark bluish or lead color, sometimes with a greenish tinge, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the center, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish-gray. Those of inferior quality are of a lighter color, sometimes reddish or nearly white, of a loose texture, with a large cavity in the center, communicating externally by a small hole through which the fly has escaped.

Galls have a bitter, very astringent taste, and when whole are inodorous or nearly so, but bruised or in powder they have a decided and peculiar though not very strong odor.

Galls owe their medicinal virtues to a tannin, usually known as *gallo-tannic acid,* which appears to exist in the galls, in part, at least, as a glucoside, but one very easily broken up by ferments like pectase, into glucose and *di-gallic acid,* $C_{14}H_{10}O_9$, therefore, extractable from the galls. Galls yield, on an average, from 65 to 77 per cent. of tannin. (See *Acidum Tannicum* and *Acidum Gallicum.*) All the soluble matter of galls is taken up by forty times their weight of boiling water, and the residue is tasteless. Alcohol dissolves seven parts in ten, ether five parts. A saturated decoction deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and hydrochloric acids and the precipitants of tannic acid. The infusion of galls reddens litmus paper and is rendered orange by nitric acid. Infusion of galls is rendered more permanent by the addition of 10 per cent. of glycerin.

Galls are formed on a number of trees and shrubs, including oaks, rhus, rhododendron, juniper, eucalyptus and sage. Hartwich (*Arch. d. Pharm.,* 1905, p. 584) illustrates these several varieties and discusses their composition. Richter gives minute descriptions of the origin, structural characteristics and microscopical appearance of galls in *Ph. Zentralh.,* 1912, p. 533. Feist and Haun have published (*A. Pharm.,* 1913, ccli, 468) an article on the constitution of the tannin in Turkish and Chinese galls. *Chinese galls* are produced on the leaves of *Rhus semialata* Murray by the deposited ova of an aphis or plant louse. They are irregularly spindle-shaped, often more or less bent, with obtusely pointed protuberances, about two inches long by an inch in diameter at the central thickest part, of an ash color and a soft velvety feel, very light, hollow, with translucent walls about a line in thickness, of a slight odor recalling that of ipecac, and a bitter astringent taste. The Chinese make great use of this product both in dyeing and as a medicine. Chinese galls contain 65 per cent. of tannic acid identical with that of the official galls. An inferior kind of galls is produced in great quantities in England, by the attack of the *Cynips kollari* of Hartig, upon the common English oak; but they have been ascertained to contain little tannic acid, and are of little value.

Kraemer (*Bot. Gaz.,* 1900, p. 275) made a microchemical study of American galls. These closely resemble the Aleppo variety and are formed on *Quercus coccinea* Moench and *Q. imbricaria* Michx. by *Cynips aciculata.* Kraemer found the chemical constituents to vary with the development of the insects. At the chrysalis stage gallic acid is more abundant than when the winged insect is developed. Texas galls are formed on the live oak (*Q. vireus*), California oak balls are formed on *Q. lobata.*

From the so-called gall-wax of certain kinds of galls, M. Nierenstein obtained a nitrogenous constituent, $C_{13}H_{17}O_6N$, which is probably a lævorotatory *galloleucin.* (*Z. P. C.,* 92, 53.)

Uses.—Galls have a powerfully astringent action, but are no longer prescribed internally. Nutgalls may be used externally for the same purposes as tannic acid.

Dose, five to fifteen grains (0.3–0.9 Gm.).

GAMBIR. U. S. (Br.)

GAMBIR [Pale Catechu]

"Gambir is the dried aqueous extract prepared from the leaves and twigs of *Ourouparia Gambir* (Hunter) Baillon (Fam. *Rubiaceæ*). Gambir yields not less than 70 per cent. of water-soluble extractive and not less than 60 per cent. of alcohol-soluble extractive." *U. S.* "Catechu is an extract of the leaves and young shoots of Uncaria Gambier, *Roxb.*" *Br.*

Catechu, *Br.;* Catechu Pallidum, Terra Japonica, Gambier, Cutch; Cachou Clair, Gambir Cubique, *Fr.;* Gelbes Katechu, Gambir-Catechu, *G.;* Catecu, *It., Sp.*

Ourouparia Gambir (Hunter) Baillon (*Uncaria Gambier* Roxb.) is a climbing shrub with slender stems somewhat thickened at the nodes; leaves opposite, stipulate, glabrous, ovate or oblong, entire, rounded at the base, but abruptly attenuated at the summit. The flowers are small and crowded into a dense globular head on a hairy receptacle; the flower heads are borne on long axillary peduncles which bear in the middle a whorl of bracts. At the point where these bracts occur the peduncle breaks after the falling of the inflorescence and the remainder of the peduncle becomes elongated and curved into hooks by means of which the plant climbs. Corolla gamopetalous, trumpet-shaped, tube slender; fruit one inch long, pericarp dry, dehiscing vertically into two valves; seeds very numerous.

It is a native of the Malay Archipelago and is largely cultivated in the islands of Bintang, Singapore, Prince of Wales and in British North Borneo. The gambir is prepared by lopping off the leaves, shoots, and twigs of the plant, chopping them into pieces, and throwing them into a pot filled with boiling water. Upon the exhaustion of the material, the decoction is poured into copper pans, evaporated to a syrupy consistency and cooled. During the cooling process, the liquor is induced to crystallize by the workman who rapidly works a wooden stick up and down in the extract, until a mass the consistency of soft clay is obtained. This mass is finally turned out, and cut into cubes, which are put upon trays and smoke-dried. (See also *P. J.,* 1892, 1003.) This extract, which is known by the native Malays as *pinang* or *siren* was first brought to the attention of the profession by Campbell.

Most of the commercial article is shipped from Singapore to London and Hamburg. The natives of Malay distinguish four different kinds: 1. *Gambir bulat* or *round Gambir,* which occurs in biscuit-like pieces and is mostly used for chewing. 2. *Gambir papan* or *table Gambir* which occurs in yellowish-brown thin tablets and is also used in chewing. 3. *Gambir paku* (*nail* or *finger Gambir*) which occurs in long black sticks resembling licorice extract. 4. *Gambir dutoor* or *cube Gambir.* The latter is the form in which it is usually employed in pharmacy. Gambir is also imported in large blocks, being used in this form for dyeing and tanning. Most of the drug is imported into this country in bags from London.

Good gambir should occur in a hard compact mass, breaking up, when the adhering mat is removed, into distinct cubes of a brownish-black color externally, and a deep mahogany-red with an occasional streak of yellow internally. It should not steam when the mat is opened. From this quality it grades down to a stuff which has been prepared by mixing the material obtained by reboiling the exhausted leaves with various mixtures. This lowest grade is not in cubes, steams when opened, frequently shows large patches of black or dirty blue color, and often has a sour fetid odor; its color varies from black to light-brown. None of the finest varieties of gambir, such as are used by the natives for chewing, occur to any extent in American commerce. Prebble records his examination of a cube gambir of fine appearance which contained a large percentage of starch. (*P. J.,* 1893, 21.)

Description and Physical Properties.—"*Unground Gambir.*—Masses approximately cubical or rectangular, from 20 to 30 mm. in diameter; externally pale grayish-brown to reddish-brown, more or less dull and porous; friable, internally of a light brown or dark gray color; inodorous; taste bitterish and very astringent.

"*Powdered Gambir.*—Light brown; mostly masses of acicular crystals which are branched or interlacing and somewhat refractive of polarized light; starch grains few, single or compound, of variable shapes, from 0.005 mm. to 0.030 mm. in diameter; epidermal fragments and thick-walled, wavy, non-glandular hairs up to 0.350 mm. in length, very few.

"Macerate 1 Gm. of Gambir with 50 cc. of water, and filter: separate portions of this filtrate should give an intense, green color with dilute ferric chloride T.S. and no precipitate with copper sulphate T.S.

"**Assay.**—Proceed as directed under water-soluble extractive, and alcohol-soluble extractive." *U. S.*

Catechu is described in the Br. as follows: "In cubes, sometimes more or less agglutinated, each side measuring about twenty-five millimetres. Dark reddish-brown externally, pale cinnamon-brown internally, porous and friable. When examined under the microscope they are found to consist chiefly of minute acicular crystals. No odor; taste at first bitter and very astringent, but subsequently sweetish. Almost entirely soluble in boiling *water*. Not less than 80 per cent. is soluble in *alcohol* (90 per cent.); the alcoholic solution made strongly alkaline with *solution of sodium hydroxide* and shaken with *petroleum spirit* imparts to the latter a brilliant green fluorescence (distinction from Black Catechu); the residue insoluble in *alcohol* (90 per cent.) exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent.; ash of the powder not more than 8 per cent." *Br.*

The microscopical appearance of gambir is very characteristic and Brumwell (*J. Soc. Chem. Ind.*, 1911, p. 475) illustrates the appearance of commercial specimens. Gambir is light and porous, so that it floats when thrown in water. It is partially soluble in cold water, and almost wholly so in boiling water, which deposits a portion upon cooling.

Nees von Esenbeck found gambir to contain from 36 to 40 per cent. of *catechutannic acid,* also called *catechu red* or *mimotannic acid,* and also from 20 to 30 per cent. of a peculiar principle called *catechuin, catechin,* or *catechuic acid. Catechin,* when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, melting at 217° C., unalterable in the air if dry, fusible by heat, very slightly soluble in cold water, with which it softens and swells up, soluble in boiling water, which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper, and, though coloring solution of chloride of iron green, and producing with it a grayish-green precipitate, differs from tannic acid in not affecting a solution of gelatin. The very great discordance of different authors as to its formula seems to be explained by some experiments of Etti (*Ann. Ch. Ph.*, clxxxvi, p. 327), who showed that *catechin,* $C_{19}H_{18}O_8$, readily gives at 100° C., or even when kept for some time over sulphuric acid, an anhydride, $C_{38}H_{34}O_{15}$, and at 160° C. a second anhydride, $C_{38}H_{32}O_{14}$, which, mixed in varying proportions, explain the varying results. Gathercoal (*J. A. Ph. A.*, 1924, xiii, 103) reached the conclusion that catechutannic acid, which he found to be present from 45 to 55 per cent., is one of the anhydrides of catechin, which is present to the extent of 30 to 40 per cent. Catechin possesses no acid properties, when heated, however it is converted into catechutannic acid which is similar in its properties to kinotannic acid. *Rubinic* and *japonic* acid are names indefinitely applied to derivatives of catechutannic acid. *Protocatechuic acid,* $C_7H_6O_4$, does not exist in catechu or gambir but is produced when certain tannins, resins or gum resins are heated with potassium hydroxide. *Pyrocatechin* or *catechol,* $C_6H_6O_2$, is a product of the destructive distillation of many tannins or vegetable extracts.

Perkin and Yoshitako (*P. J.*, 1902, p. 530) have made an elaborate investigation of gambir and acacia catechus. They find three catechins, designated respectively as (*a*), (*b*), and (*c*). Catechin (*b*), $C_{15}H_{14}O_6 + 4H_2O$, occurs in air dried, colorless needles, melting at 175° to 177° C., and gives, on fusion with alkali, phloroglucinol, protocatechuic acid, and an acid resembling acetic acid. Catechin (*c*), $C_{15}H_{14}O_6$, air dried, contains no water of crystallization and forms colorless prisms, melting at 235° to 237° C. Catechin (*a*), $C_{15}H_{14}O_6 + 3H_2O$ (or less probably $C_{14}H_{14}O_6 + 3H_2O$), air dried, forms colorless needles, melting at 204° to 205° C.

Enormous quantities of gambir are used both in Europe and America in tanning, calico printing, dyeing, as an ingredient in boiler compounds for preventing the hard scaly incrustation caused by certain kinds of water, and other processes requiring tannic acid.

Vanderkleed and E'we call attention to the fact that the apparent alcohol soluble content of gambir may be unduly raised by the high moisture content of some of the commercial varieties, which they report as containing over 21 per cent. of moisture, all of which would be calculated in the alcohol soluble extractive by the ordinary methods in which no allowance is made for water. (*J. A. Ph. A.*, 1914, 1685.)

Uses.—Gambir is a serviceable remedy in those cases where astringents are indicated. The complaints to which it is best adapted are *diarrhea* dependent on debility or relaxation of the intestinal mucous membrane, and *passive hemorrhages,* particularly from the uterus. A small piece held in the mouth and allowed slowly to dissolve is an excellent remedy in *relaxation of the uvula* and the *troublesome cough* which depends upon it. Applied to *spongy gums,* in the state of powder, it sometimes proves useful.

Dose, from ten grains to half a drachm (0.65–2.0 Gm.).

Off. Prep.—Tinctura Gambir Composita, *U. S. (Br.)*; Tinctura Pectoralis (from Compound Tincture), *N. F.*

GELATINUM. U. S., Br.

GELATIN Gelat.

"A product obtained from animal tissues, such as skin, ligaments, and bones." *U. S.* "Gelatin is the air-dried product obtained by the action of boiling water on animal tissues such as skin, tendons, ligaments, and bones." *Br.*

Gélatine Officinale, *Fr. Cod.;* Grenatine, Colle de Flandre purifiée, *Fr.;* Gelatina alba, *P. G.;* Weisser Leim, Gallerte, *G.;* Gelatina, *Sp.*

The *collagens* are a class of albuminoids abundant in bones, skin, tendons, cartilage and similar tissues of animals. These collagens unite with water at high temperatures, producing the compounds known respectively as glue and gelatin which differ from each other mainly in the character of the raw stock from which they are manufactured and also in the relative amounts of *glutin* and *chondrin* which they contain; glutin being present in higher proportions in glue, to which it imparts its great adhesive power and chondrin giving to gelatin its greater gelatinizing power. The commercial stock from which much edible gelatin is produced is prepared from clean bones by treatment with hydrochloric acid to remove calcium phosphate and is known as *ossein.* Among the commercial varieties of these substances may be mentioned *hide glue* and *bone glue,* which are commercially the most important.

The bones and animal matter from which the best qualities of gelatin are prepared are carefully selected so as to be free from decomposed products and odorous substances. The hot solution of gelatin must be thoroughly clarified if the so-called sparkling gelatin is to be made.

On account of the tendency to decompose during the process of manufacture, it is sometimes the practice to employ preservatives such as sulphurous acid, which, being frequently used in excessive amounts, remain in the finished product as contaminating substances. Sometimes metallic impurities, as lead, copper, zinc, and arsenic, are present from the apparatus or substances used during the manufacture of the gelatin.

After the gelatin solution has been purified by the use of animal charcoal or other appropriate means, it is brought to the proper degree of concentration and is then allowed to solidify or gelatinize. It is now cut up into slabs which are rapidly dried in long, continuous mechanical drying machines where it is supported upon netting to allow free access of the warm, dry air currents which pass over it.

The surface of sheet gelatin is covered with lozenge-shaped marks, due to impressions left by the knotted netting upon which it is dried. Shred gelatin is made by cutting sheet gelatin into very narrow shreds by a shearing-machine. (See *Nat. Drug.,* 1894, 134.) Granulated gelatin is the form in which it usually appears upon the market in the best grades at the present time. *Gelatose* and *paragelatose* are terms used by Dastre and Floresco to define gelatin which has lost its power of "gelatinization" through the action of ferments or microbes, saline solutions, or the prolonged action of boiling water. (*P. J.,* 1895, 454.)

Description and Physical Properties.—"In sheets, flakes, shreds, or as a coarse or fine powder. It is colorless or yellowish, and has a very slight, characteristic odor and taste. When dry it is stable in the air, but when moist or in solution it decomposes. Gelatin is insoluble in cold water, but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its own weight of water. It is soluble in hot water, acetic acid, and in a hot mixture of glycerin and water. It is insoluble in alcohol, chloroform, ether, benzene, carbon disulphide, and in fixed or volatile oils.

"An aqueous solution of Gelatin (1 in 100) yields no precipitate with copper sulphate T.S. or mercuric chloride T.S., but is precipitated by solution of chromium trioxide or trinitrophenol T.S. Even a very dilute solution of Gelatin (1 in 5000) is at once rendered turbid by the addition of tannic acid T.S.

"A hot solution of Gelatin in distilled water (1 in 40) is free from a putrid odor, and is not more than slightly acid to litmus paper. In a layer 2 cm. in thickness the solution is only slightly opalescent and on cooling to 6° C., and standing for several hours, it forms a firm, transparent or translucent jelly. Incinerate 0.5 Gm. of Gelatin: it yields not more than 2 per cent. of ash. Dissolve this ash with the aid of heat in a slight excess of hydrochloric acid and a few drops of nitric acid: the resulting solution diluted with distilled water to 25 cc. meets the requirements of the test for *heavy metals,* page 439. Heat 1.5 Gm. of Gelatin with 30 cc. of hydrochloric acid (1 in 4) in a 150 cc. Erlenmeyer flask on a water bath, and, when the Gelatin has dissolved, add 3 cc. of bromine T.S., and heat on a water bath for thirty minutes, shaking the flask occasionally. Then add 0.5 Gm. of potassium iodide and follow it with 0.5 cc. of a 25 per cent. solution of stannous chloride. Heat the solution for five minutes on a water bath, cool and subject it to the test for *arsenic,* page 428. The stain, if any, is not greater than that produced in a test made with the same quantities of the reagents and 2 cc. of the standard arsenic test solution. Dissolve 20 Gm. of Gelatin in 150 cc. of hot distilled water in a flask having a round bottom and a long neck, add 5 cc. of phosphoric acid and 1 Gm. of sodium bicarbonate, and at once connect the flask with a condenser. Distil 50 cc., receiving the distillate under the surface of 50 cc. of tenth-normal iodine. Acidulate the distillate with a few drops of hydrochloric acid, add 2 cc. of barium chloride T.S., and heat on a water bath until the liquid is nearly colorless. The precipitate of barium sulphate, if any, when filtered, washed and ignited, weighs not more than 0.003 Gm., corresponding to not more than 0.004 per cent. of sulphur dioxide, correction being made for any sulphate which may be present in 50 cc. of the tenth-normal iodine.

"NOTE.—Gelatin to be used for capsules for medicines may contain not more than 0.15 per cent. of sulphur dioxide." *U. S.*

"In almost colorless, translucent sheets or shreds. Insoluble in *alcohol* (90 per cent.) and in *ether;* soluble in *acetic acid.* A solution in hot *water* (1 in 50) is inodorous and solidifies to a jelly on cooling. An aqueous solution yields a precipitate with *solution of tannic acid,* but not with solutions of other acids, or with dilute solution of *alum, solution of lead acetate,* or *T. Sol. of ferric chloride.* Ash not more than 2 per cent." *Br.*

Gelatin is largely used for making *capsules.* Certain medicines are so offensive to the taste, and consequently so likely to cause nausea, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. Capsules for enclosing dry powders are ovoid in shape and, after being filled with the powder by the pharmacist, are closed by putting upon the open end a rounded gelatin cap and pressing it down tightly. When so-called *soft capsules* are desired, a small quantity of glycerin is introduced into the gelatin mass; this makes the film elastic by preventing its drying completely. Gelatin capsules are now made in enormous quantities by machinery.

Formalized gelatin is but very slightly or not at all affected by the gastric juice, but is slowly dissolved in the intestines. Advantage has been taken of this fact to manufacture capsules for the administration of drugs which it is desirable should not come in contact with the gastric mucous membrane. A special brand of such capsules is on the market under the name of *glutoid capsules.* These are called *enteric capsules.* Scoville (*J. A. Ph. A.*, 1915, p. 1243) recommends that the sealed capsules be immersed in a 1 per cent. aqueous formaldehyde solution for thirty seconds, then dried quickly and allowed to stand two weeks before use. If stronger formaldehyde solutions are used or the time of treatment extended, the capsules become insoluble in the intestines.

Uses.—In 1896 Dastre and Floresco (*C. R. S. B.*, 1896, ii, iii), while engaged in a research of the physical properties of gelatin, made the observation that injection of gelatin greatly accelerated the coagulation of the blood. This observation led to a good deal of experimental study as well as clinical use of gelatin in the treatment of hemorrhage. Although it was abundantly demonstrated that the injection of gelatin, either hypodermically or intravenously, had a marked effect in controlling *hemorrhage* through its effect in hastening clot formation. It was soon found that the difficulty of sterilizing solutions of gelatin greatly limited the clinical value of the treatment. Because of its source, gelatin is very prone to be contaminated with tetanus spores which are, as is well known, highly resistant to heat; and a number of fatal cases of tetanus have followed the subcutaneous injections of gelatin solutions. Although there is some evidence that the use of gelatin by mouth has an effect on the coagulability of the blood, the question has never been definitely settled. The discovery of other clot-accelerating substances (see *Blood,* Part II) in more recent years has led to a great diminution in the use of gelatin for its effects on blood coagulation.

In the milder forms of internal hemorrhages such as certain cases of *hemoptysis* or of *menorrhagia* gelatin feedings may be tried, at least for a time. For this purpose from a half to two ounces (15.5–62 Gm.) of commercial gelatin may be dissolved in four or five times as much water, suitably flavored and seasoned, and allowed to cool; this is eaten in the same manner as ordinary table gelatin. In local hemorrhages, as *epistaxis,* a warm 10 per cent. solution may be applied directly to the bleeding point. It has also been employed in the treatment of *diarrhea* and *mucous colitis* with asserted benefit.

Gelatin chemically belongs to the group of proteins, and under the influence of digestion is converted into amino-acids, which are the form in which protein foods are utilized. It is not capable, however, of furnishing all the protein needs of the body because of the absence of the tyrosin and tryptophane groups in the products of its breaking down. Because of its ease of digestion it is a very valuable accessory food in various disease conditions when the digestive powers are reduced.

Dose, one-half to one ounce (15.5–31 Gm.).

Off. Prep.—Gelatinum Glycerinatum, *U. S.;* Suppositoria Glycerini, *Br.* (Vehicle for lamellæ in Br.)

GELATINUM GLYCERINATUM. U. S.

GLYCERINATED GELATIN Gelat. Glycerin.

Gelatina Glycerinata, Gelatinum Glycerini; Glycerin Jelly; Gelée Glycérinée, *Fr.;* Glycerinleim, *G.*

"Gelatin, 100 Gm.; Glycerin, 100 Gm.; Water, a sufficient quantity to make 200 Gm. Pour upon the gelatin sufficient water, which has been previously boiled and cooled, to cover it, allow it to stand one hour, pour off the water, and allow the gelatin to drain for a few minutes. Then transfer it to a dish, add the glycerin, and heat on a water bath until the gelatin is dissolved. Strain the solution while hot, transfer to a tared dish, and continue the heat on the water bath until the product weighs 200 Gm. When cold, cut the mass into pieces, and preserve in well-closed containers." *U. S.*

Uses.—Glycerinated gelatin is used as a vehicle in making gelatin suppositories, bougies, etc. The National Formulary IV introduced a class of preparations termed "*Glycerogelatins*," to be used in dermatological practice. (See Part III.)

GELSEMIUM. N. F. (Br.)

GELSEMIUM Gelsem. [Yellow Jasmine Root, Yellow Jessamine]

"Gelsemium consists of the dried rhizome and roots of *Gelsemium sempervirens* (Linné) Persoon (Fam. *Loganiaceæ*). Gelsemium contains not more than 2 per cent. of foreign organic matter." *N. F.*

"Gelsemium Root is the dried rhizome and root of Gelsemium nitidum, *Michaux*." *Br.*

Gelsemii Radix, *Br.;* Gelsemium Root, Yellow Jasmine, Yellow Jessamine, Carolina or American Yellow Jessamine, Yellow or Evening Trumpet Flower; Gelsemium, *Fr. Cod.;* Jasmin sauvage, *Fr.;* Gelsemie, Giftjasmin, *G.;* Gelsemio, *Sp*

The *yellow* or *Carolina Jessamine* (*Gelsemium sempervirens*) is one of the most beautiful climbing plants of our Southern States, ascending lofty trees, and forming festoons from one tree to another, and during its flowering season, in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth, and shining; the leaves opposite, nearly persistent, short, petiolate, lanceolate, entire, dark green above, and paler beneath; the flowers in axillary clusters, large, of a deep-yellow color, and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, 2-loculed, compressed capsule containing flattened seeds. The plant grows in rich, moist soils along the sea-coast from Virginia to the south of Florida and Texas. The flowers are said to be poisonous. The drug is collected in autumn, washed and dried. The commercial supplies come chiefly from Virginia, North and South Carolina and Tennessee. *Gelsemium elegans* Benth., of upper Burma, is an extremely poisonous creeper which contains gelsemine or an allied alkaloid.

This official plant must not be confounded with the true yellow jasmine of Madeira, often planted in the Southern States, which is the *Jasminum odoratissimum* L., which also has very fragrant yellow flowers.

Description and Physical Properties.—"*Unground Gelsemium.*—Rhizome cylindrical, usually in pieces from 3 to 20 cm. in length and from 3 to 30 mm. in diameter; externally light yellowish brown, longitudinally wrinkled, with purplish brown longitudinal lines and transverse fissures; the upper surface with a few stem-scars; fracture tough, splintery, internally light brown or pale yellow, bark thin, wood distinctly radiate, excentric, pith disintegrated. Roots light brown, fracture one-half transverse, the other oblique or splintery. Odor slight; taste bitter.

"*Structure.*—Rhizome with a strong development of cork, the walls being grayish or yellowish brown and more or less lignified; a cortex made up chiefly of parenchyma containing starch and having in the outer portion small scattered groups of stone cells or fibers, and in the inner portion in the region of the medullary rays prisms of calcium oxalate; woody portion made up of broad wedges consisting of large tracheæ and thick-walled tracheids and separated by medullary rays, the cells of which are usually strongly lignified in the xylum but non-lignified in the phlœm and contains starch or prisms of calcium oxalate; an internal phlœm, the cells forming distinct, more or less rounded groups, the latter being partly surrounded by a thin-walled starch-bearing pith.

"*Powdered Gelsemium.*—Dark yellow, tracheæ with bordered pores numerous and conspicuous; spiral tracheæ and bast-fibers few; thick-walled tracheids long and narrow, strongly lignified; starch grains spherical, from 0.004 to 0.012 mm. in diameter; calcium oxalate in monoclinic prisms from 0.015 to 0.032 mm. in length; occasional groups of stone cells or fibers, the walls being very thick, porous and strongly lignified." *N. F.*

"In nearly cylindrical pieces about fifteen centimetres or more long, and usually from six to eighteen millimetres thick; occasionally with fibrous rootlets attached. Fracture splintery. In transverse section, a thin cortex, and a porous, yellowish, distinctly radiate wood with numerous, conspicuous, straight medullary rays. Rhizome usually with a brown or dark brownish-violet cork, often much fissured; nearly straight, and exhibiting silky fibres in the bast. Root yellowish-brown, finely wrinkled, and somewhat tortuous. Slightly aromatic odor; taste bitter." *Br.*

The chief diagnostic feature of gelsemium rhizome is seen in its cross section which shows four masses of internal phloem on the inner face of the xylem zone. For studies of the structure of gelsemium, see *A. J. P.*, 1898, 398; *A. J. P.*, 1899, 422; *D. C.*, 1901, 244; *Merck's Rep.*, 1908, p. 86. Tunmann (*Ph. Zentralh.*, 1907, p. 679) has made a pharmacognostic study of gelsemium and has proposed its identification through the microsublimation of æsculin. Tutin (*P. J.*, Feb. 10, 1912) has shown that the sublimate obtained by Tunmann from gelsemium root must have consisted of scopoletin. Tutin further states that "The detection of scopoletin in gelsemium may prove to be a valuable means of distinguishing this drug from others of a similar appearance, such as that derived from *Gelsemium elegans* Benth., but it is doubtful whether the sublimation method is the most convenient one. If 0.5 gramme of ground gelsemium be heated in a test tube with chloroform, the mixture filtered, and the filtrate shaken with water to which a few drops of dilute ammonia have been added, the aqueous layer, on separation, will be found to show a distinct, blue fluorescence, thus indicating the presence of scopoletin."

Sayre (*A. J. P.*, 1897, 8) found specimens of the rhizome mixed with considerable proportions of the stem. The latter differs microscopically from the rhizome in possessing collenchyma-containing chloroplastids in the outer region of the cortex and sclerenchyma fibers in the pericycle. Ingham (*A. J. P.*, 1897, 234) found that there was not much difference between the root and rhizome in alkaloidal value, but the stem does not appear to contain either gelsemine or gelsemic acid. (See also *A. J. P.*, 1897, 140.) Gelsemium yields its virtues to water, and readily to diluted alcohol.

Constituents.—In 1855 Henry Kollock found in gelsemium gum, starch, pectic acid, albumen, gallic acid, fixed oil, a fatty resin, a dry acrid resin, yellow coloring matter, volatile oil, extractive, lignin, a peculiar alkaloid called *gelsemine*, and mineral salts. The alkaloid, however, was not obtained sufficiently pure to admit of a full investigation of its properties. Theo G. Wormley (*A. J. P.*, 1870) obtained pure gelsemine from the root and a peculiar acid, which he called *gelseminic* (*gelsemic*) *acid*.

Wormley obtained the acid by acidulating a concentrated aqueous solution of the drug and extracting with ether. (For details of his method, see *U. S. D.*, 19th ed., p. 578.) The acid, when pure, is colorless, inodorous, almost tasteless, and readily crystallizable, usually in groups or tufts of fine needles. The action of concentrated nitric acid upon gelsemic acid or any of its salts, produces a yellow, reddish, or red solution, which, if treated with ammonia in excess, becomes of a deep blood-red color, lasting for hours. The one-thousandth of a grain will exhibit these changes. Potassium, sodium, or ammonium hydroxide, added to the acid, cause it to become intensely yellow, and form with it highly fluorescent solutions. The acid is fusible, and, at a high heat, volatilizable without change. Robbins (*B. Chem. G.*, 1876, 1182) stated that it was identical with æsculin (the glucoside of the horse-chestnut), and gave it the formula $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$. But Coblentz (*Proc. A. Ph. A.*, 1897, 225) showed that it differs from æsculin in several particulars, and gave for its formula $C_{13}H_{11}O_5$, which melts at 206° C. E. Schmidt believes that Wormley's gelsemic acid is identical with *scopoletin* derived from scopola root, and gives the name as *β-methylæsculin*, $C_9H_5(CH_3)O_4$.

Gelsemine as obtained by Wormley is a brittle, transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it. It softens at 38° C., and fuses at 45° C. The pure base gives no color reaction with strong nitric acid, and the mixture is scarcely changed in color by heating. Strong sulphuric acid has no apparent action upon it; but if to the mixture a little manganic oxide be added and then rubbed with a glass rod, a deep crimson-red is obtained, passing to green. This reaction is so delicate that it can be demonstrated with a solution of 1 in 100,000. If this reaction be performed upon the pure alkaloid, the color may be sufficiently intense to cause it to be mistaken for strychnine, but if a parallel experiment be carried on with strychnine, the two alkaloids cannot be mistaken, for the strychnine gives an intense purple, passing to red. It was probably not a pure substance. Moore (*Tr. Chem. Soc.*, 1910, xcvii; 1911, xcix) gives the formula as $C_{20}H_{22}O_2N_2$. He also confirms the presence of a second alkaloid *gelseminine*, originally announced by F. A. Thompson (*Ph. Era*, 1887, p. 3).

Sayre (*J. A. Ph. A.*, 1912, p. 458; 1913, p. 436; 1914, p. 314, and 1915, p. 60) has found two alkaloids differing in physiological activity and color reactions, the one of which he called gelseminine (the former name for the combination of the two), and the other *gelsemoidine*, which was later changed to *sempervirine*. This latter alkaloid is similar in some of its properties to cinchonamine, particularly in the matter of the insolubility of its salts in water. Sayre also calls attention to the fact that the alkaloid commercially supplied under the name gelseminine is usually the crystalline alkaloid gelsemine. He states that the principles obtained by him show the following color reactions with sulphuric acid and manganic oxide: *Gelsemine*, at first crimson, then green, and finally yellow; *gelseminine*, at first brown, then pink, and finally yellow; *gelsemoidine*, at first purple and finally blue.

Uses.—According to the researches of Cushny (*A. E. P. P.*, 1892, xxxi, 49) gelseminine is so much more powerful than gelsemine that it is improbable that the latter alkaloid plays any part in the effect of the whole drug in mammals. Gelseminine is a depressant to the centers in the spinal cord and, in large doses, also paralyzes the peripheral motor nerves. Gelsemine acts, in the frog, much like strychnine, causing convulsions, by stimulating the spinal cord, which are followed by paralysis due to an effect on the motor nerves. In toxic quantities gelsemium lowers the blood pressure, probably by a direct action on the heart, but death is usually brought about through respiratory failure. When locally applied, or if given internally in poisonous dose, it causes dilatation of the pupil with loss of accommodation.

Formerly gelsemium was used as an arterial sedative and febrifuge in various sthenic *fevers*, but is probably useless for this purpose. Bartholow (*Pract.*, 1870) has recommended it in spasmodic disorders, as *asthma* and *whooping cough*. It is, at present, rarely used except in the treatment of *neuralgias*, especially those involving the facial nerves. The mode of its action in these cases is obscure, but there is considerable clinical evidence of its utility.

Toxicology.—The symptoms of gelsemium poisoning are: dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration, reducing the frequency and force of the pulse, and the frequency of respiration. After very pronounced poisonous doses the symptoms which have just been enumerated are intensified: double or impaired vision, ptosis, dilated insensible pupils, falling of the lower jaw, loss of power of enunciation, and excessive muscular relaxation are associated with slow, labored breathing, which in some cases is interrupted by violent spells of dyspnea; consciousness is long unimpaired, but is apt to be lost before death, and in rare cases unconsciousness has been present, even although recovery followed. Of the various symptoms of gelsemium poisoning the most characteristic are the dropping of the jaw and the ocular manifestations, combined with general muscular relaxation. The effects usually begin in half an hour, but sometimes almost immediately. According to Wormley, death has occurred at periods which vary from one to seven and a half hours. Twelve minims of the fluidextract are said to have proved fatal to a boy three years old, and thirty-five drops of a tincture of the bark have caused death in one hour and a half. In several instances a drachm of the fluidextract has, under treatment, been recovered from.

The treatment of poisoning by gelsemium should consist in evacuating the stomach, maintaining absolute rest in the horizontal position, keeping up the bodily temperature, if required, by external warmth, and administering spinal and arterial stimulants. We have very little experimental data as to the physiological antidotes to gelsemium. Our general knowledge indicates that ammonia, strychnine, and digitalis given hypodermically should be of service in the treatment of the poisoning. Artificial respiration is of service.

Dose, of gelsemium, one-half to two grains (0.03–0.13 Gm.).

GENTIANA. U. S. (Br.)

GENTIAN Gentian. [Gentian Root]

"Gentian is the dried rhizome and roots of *Gentiana lutea* Linné (Fam. *Gentianaceæ*). Gentian yields not less than 30 per cent. of water-soluble extractive." *U. S.* "Gentian Root is the dried rhizome and root of Gentiana lutea, *Linn.*" *Br.*

Gentianæ Radix, *Br.;* Yellow Gentian Root, Bitter Root, Fel Root; Gentiane (Racine), *Fr. Cod.;* Racine de Gentiane, Gentiane jaune, *Fr.;* Radix Gentianæ, *P. G.;* Enzianwurzel, Bitterwurzel, Rother Enzian, *G.;* Genziana, *It.;* Genciana (Raiz de), *Sp.*

Gentiana lutea or *Yellow Gentian* is among the most remarkable of the species which compose this genus, both for its beauty and large size. From its perennial rhizome—which is thick, long and branching—an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, ovate, acute, five- to seven-nerved leaves of a bright-green color, and somewhat glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow color, and arranged in axillary cymes along the upper part of the stem. The calyx is gamosepalous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply divided into five or six lanceolate, acute segments; the stamens are five or six, and shorter than the corolla. The fruit is an ovate capsule containing winged seeds. The plant grows among the Apennines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe and Asia Minor. It is stated by Bourquelot and Hérissey that in order to develop the deep colored fracture preferred by many druggists the root is frequently submitted to fermentation by heaping it up into a mass which becomes heated. Gentian root which has thus been treated is said to yield 27 per cent. less extractive than does that which has been properly dried.

The crude drug comes to the United States in burlap bags and bales chiefly from Marseilles, Bordeaux and Paris, France and Antwerp and Brussels, Belgium. Hamburg, Trieste and Budapest also ship this drug.

Several other species possess analogous virtues, and are used for similar purposes. The roots of *G. purpurea* L. and *G. punctata* L., inhabiting the same regions as *G. lutea,* and of *G. pannonica* Scopoli, growing in Austria, are said to be often mingled with the official. All of these are usually smaller than the official article, the *G. purpurea* rhizomes, which occasionally are admixed with the official, being crowned with a number of aerial stem bases with scaly remains of leaves attached. The German Pharmacopœia permits the use of the rhizome and roots of these three species. The *G. macrophylla* of Pallas is used in Siberia.

G. quinquefolia L. (*G. quinqueflora* Lam.), growing throughout the northern and northwestern States, is said to be much used in domestic practice. In Europe the rhizome of *G. asclepiadea* L. has been admixed with the official rhizome. According to Vogl, it can be detected by the abundance of lignified prosenchymatous elements and stone cells, the genuine powder containing scarcely any lignified elements other than large reticulated vessels. (*O. Z.,* 1903, 141.)

One indigenous species, *G. Catesbæi* (now *G. Elliottii* Chapm.), growing in the southern States, formerly had a place in the secondary list of the U. S. Pharmacopœia, and is reputed to be but little inferior to the official species. This plant, popularly called *blue gentian,* has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite ovate-lanceolate leaves and pale blue flowers, crowded, nearly sessile, and axillary or terminal. It grows in the grassy swamps from Virginia to Florida, where it flowers from September to December. It may be given in powder in the dose of from fifteen to thirty grains, or in the form of extract, infusion, wine or tincture.

Powdered gentian has been adulterated with ground olive stones, ground peanut shells, and even quassia root. These are all readily detected by means of their lignified tissues, which may be seen through the use of the microscope. Gadd and Gadd assert (*P. J.*, 1905, xxi, p. 439) that adulterations of gentian are most readily detected by means of the microscope, but that good evidence of quality is also furnished by the yield of extract, which should be about 40 per cent.

As found in commerce, gentian is in pieces of various dimensions and shapes, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the rhizome and root cut transversely.

Description and Physical Properties.—"*Unground Gentian.*—In pieces nearly cylindrical, sometimes branched, from 5 to 40 mm. in thickness; the rhizome portions annulate and the roots longitudinally wrinkled; externally yellowish-brown; brittle when dry, tough and flexible when damp; internally yellowish-brown, with a cortex from 0.5 to 2 mm. in thickness, separated from a spongy wood by a dark brown cambium zone and distinctly radiate in appearance, especially in the region of the cambium; odor strong and characteristic; taste slightly sweetish at first, then strongly and persistently bitter.

"*Structure.*—Cork of 4 to 6 rows of thin-walled cells; secondary cortex of several rows of thick-walled cells; inner bark of many layers of more or less tangentially collapsed parenchyma and numerous sieve bundles and separated from the wood by a distinct cambium ring; medullary rays indistinct; wood rays consisting of a few large tracheæ scattered through an abundance of brown, thin-walled parenchyma.

"*Powdered Gentian.*—Light brown or yellowish-brown and consists chiefly of parenchymatous cells with fragments of scalariform or reticulate tracheæ. Starch grains and calcium oxalate crystals are few or absent. Stone cells and bast- or wood-fibers are absent.

"**Assay.**—Proceed as directed under water-soluble extractive." *U. S.*

"Parenchymatous tissue of rhizome and root abundant, containing small oil globules and minute crystals of calcium oxalate but not more than an occasional starch grain; vessels reticulated; no sclerenchymatous cells or fibres. Characteristic odor; taste at first slightly sweet but afterwards bitter. When 5 grammes of the powdered Root are macerated with 100 millilitres of *water* for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate yield on evaporation in a flat-bottomed dish not less than 0.165 gramme of residue dried at 100° C. Ash not more than 6 per cent." *Br.*

Constituents.—Kromayer, in 1862, first obtained the bitter principle of gentian in a state of purity, and gave it the name of *gentiopicrin*, and the formula $C_{20}H_{30}O_{12}$. This principle has been found in many other species of the genus *Gentiana* and seems to be a characteristic principle of the genus. It is a glucoside, crystallizing in colorless needles, which readily dissolve in water. It is soluble in 95 per cent. alcohol, but in absolute alcohol only when aided by heat; it does not dissolve in ether. A solution of sodium hydroxide forms with it a yellow solution. Under the influence of diluted acids, gentiopicrin is resolved into glucose and an amorphous yellowish-brown neutral substance named *gentiogenin*. Fresh gentian roots yield about one-tenth per cent. of gentiopicrin. Another constituent is *gentianin* or *gentisin*, $C_{14}H_{10}O_5$. It forms tasteless, yellowish prisms, subliming with partial decomposition at a temperature over 300° C. sparingly soluble in alcohol, and with alkalies yields intensely yellow, crystallizable compounds, easily decomposed by carbon dioxide. Von Kostanecki (*A. J. P.*, 1891, p. 192), by boiling gentisin with hydriodic acid, succeeded in demethylating it, and so obtained *gentisein*, $C_{13}H_8O_5$, which crystallizes with $2H_2O$ in fine straw-colored needles; these become anhydrous at 100° C.

There is a small quantity of tannin in gentian root. (See Patch, *Proc. A. Ph. A.*, 1881.)

Louis Magnes found in the root, when perfectly dried at 100° C., 15 per cent. of reducing sugar. When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence of the presence of this saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter, and having an unpleasant odor, is said to be relished by the Swiss and Tyrolese. A. Meyer (*Ph. Cb.*, May, 1882) obtained a sweet principle, which he called *gentianose*, $C_{16}H_{66}O_{31}$, by precipitation of the filtered juice with alcohol, treatment with ether, and crystallization from alcohol. It does not reduce Fehling's solution. Infusion of gentian is precipitated by tannic acid and the soluble salts of lead, but is compatible with the salts of iron. Pectin, so frequently found in fleshy roots, exists in gentian. (Bourquelot and Hérissey, *Répert de Pharm.*, 1898.) The yellow coloring matter of the root was investigated by E. V. Howell, who concludes that it is quercitrin. Tanret (*P. J.*, lxxvi, p. 87) found two glucosides, *gentiamarin* and *gentiin*. He also states (*B. G. T.*, 1905, p. 730) that in fresh roots the amount of gentiopicrin is about 1.5 per cent., but that it is destroyed in the process of drying so that dried roots contain only 0.1 per cent. Bridel (*J. P. C.*, 1920, xxii, 411) reports that the amount of the principle grows less on keeping.

Uses.—Gentian has been known from the highest antiquity and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients. The ordinary preparations of gentian are, however, almost without physiological properties except their local effects on the mucous membrane of the alimentary tract. Moorhead (*J. P. Ex. T.*, 1915, vii) has given a scientific rationale for the ancient empirical belief in the bitters, by showing that gentian markedly increased the gastric secretions in cachectic dogs. As a stimulant to gastric digestion gentian is perhaps the most popular of all bitters in the treatment of *atonic dyspepsia, anorexia,* and similar complaints. In overdose it acts as a local irritant and may occasion nausea or vomiting. The porous property of the root causes it to expand with moisture and it has been employed as a substitute for the sponge tent to enlarge strictured passages. According to Tanret (*B. G. T.*, 1905, p. 730) gentiopicrin is highly poisonous to the plasmodium and in doses of twenty to thirty grains (1.3–2.0 Gm.) is a useful remedy in *malarial fevers;* it might be pointed out in this connection that it would require between four and five pounds of dried gentian root to produce one dose of gentiopicrin.

Dose, fifteen to thirty grains (1–2 Gm.).

GERANIUM. N. F.

GERANIUM Geran. [Cranesbill]

"Geranium is the dried rhizome of *Geranium maculatum* Linné (Fam. *Geraniaceæ*). Geranium yields not more than 2 per cent of foreign organic matter." *N. F.*

Spotted or Wild Cranesbill, Storksbill; Alum Root; Racine de Bec-de-Grue tacheté, Racine de Pied-de-Corneille, *Fr;* Fleckstorchschnabelwurzel, *G.*

This indigenous herb differs from the other native species of geranium in having a perennial root stock and also in that its flowers are much larger, being from 1 to 1½ inches in diameter. The petals, which are five in number, are of a rose-purplish color and bearded at their base; the leaves are deeply five parted, the wedge-shaped lobes being irregularly notched. The fruit is a five-celled regma, the persistent 5-cleft style forming a beak-like appendage, whence the popular name of cranesbill. The plant is found throughout the United States in moist woods, thickets, and hedges, and generally in low grounds. It flowers from May to July. The rhizome should be collected in autumn. The commercial supplies of Geranium come mostly from Virginia, North Carolina, Indiana and Michigan.

Description and Physical Properties.—"*Unground Geranium.*—Rhizome cylindraceous, somewhat branched, bent, flattened and strongly tuberculated, from 2.5 to 10 cm. long and from 3 to 15 mm. in diameter; surface marked with root scars and remnant of slender roots, longitudinally wrinkled; externally dark purple-brown; internally light purple-brown; fracture short, non-fibrous, the section shows a thin bark, a distinct cambium, irregular in outline, large central pith, wood indistinct, the fibrovascular bundles few and at unequal distances. Odorless; taste strongly astringent.

"*Structure.*—A more or less irregular cork layer consisting of about 10 rows of tangentially elongated cells, the outer layers with brownish walls and a brownish amorphous content, the inner layers with colorless walls; a layer of about 5 rows of tangentially elongated oval cells; a wide layer of nearly isodiametric parenchyma containing either starch, rosettes of calcium oxalate, or tannin; distinct groups of sieve separated from the central cylinder by a broad, continuous zone of cambium; fibrovascular bundles few, radially arranged with tracheæ and tracheids and narrow medullary rays; very large pith, the cells containing starch or in a few instances rosettes of calcium oxalate.

"*Powdered Geranium.*—Purplish brown; fragments composed of cortical or pith parenchyma containing numerous, smooth, simple, ovate or ellipsoidal starch grains up to 0.035 mm. in length, with the hilum near the larger end, the inner lamellæ concentric about it, the outer excentric, rosettes of calcium oxalate up to 0.120 mm. in diameter, occasionally up to 0.145 mm. either isolated or contained within the parenchyma; fragment composed of cork cells having brownish walls and a brownish amorphous content; numerous fragments colored bluish black by ammonio-ferric alum T.S.; tracheæ small with spiral or reticulate markings; tracheids with reticulate markings or simple pores; with the exception of the tracheæ and tracheids, lignified tissue is wanting." *N. F.*

The medicinal properties of geranium are due solely to the tannic and gallic acids it contains. Henry Trimble and J. C. Peacock (*A. J. P.*, 1891, p. 265) collected the plant at periods of the year ranging from January to October, and determined the percentage of tannin as calculated for the perfectly dry drug to vary from 9.72 to 27.85 per cent. They also determined that it belonged to the class of tannins analogous to gallo-tannic acid, yielding pyrogallol on heating. They decomposed the tannin by the action of hydrochloric acid, obtaining gallic acid, glucose, and geranium red as products.

Uses.—Geranium is one of our best indigenous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and of other offensive qualities renders it peculiarly serviceable in the case of infants and of persons of very delicate stomach. *Diarrhea, chronic dysentery, cholera infantum* in the later stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage. As an application to *indolent ulcers,* an injection in *gleet* and *leucorrhea,* and a gargle in *relaxation of the uvula* and *aphthous ulcerations of the throat,* it answers the same purpose as kino, catechu, and other medicines of the same class. It is a popular domestic remedy in various parts of the United States, and is said to have been employed by the Indians.

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Geranii, *N. F.*

GLUCOSUM. U. S., Br.

GLUCOSE Glucos. [Syrupy Glucose, Liquid Glucose]

"A product obtained by the incomplete hydrolysis of starch, consisting chiefly of dextrose (d-glucose) [$C_6H_{12}O_6$], dextrins and water." *U. S.* "Glucose is a mixture of dextrose and other analogous substances, and is obtained by the hydrolysis of starch." *Br.*

Saccharum amylaceum; Saccharum uveum; Grape-sugar; Starch-sugar; Stärkezucker, Traubenzucker, Glykose, *G.*

The term "glucose" has been rather loosely applied either to chemically pure grape sugar or to a syrupy mixture containing varying amounts of dextrose. In view of the fact that the present Pharmacopœia recognizes a chemically pure sugar under the name of dextrose and the rather indefinite syrupy mixture under the name of glucose and that the medicinal properties of the two substances are quite different, it is very important that a distinction be made in the use of these words. We shall use the term "Glucose" in the Pharmacopœia sense. *Fruit sugar,* or *levulose,* is an isomeric form of glucose, found in honey and in the juice of fruits; an uncrystallizable mixture of dextrose and levulose, called *invert sugar,* is generated from cane sugar by solution in water or weak acids, and boiling. Hence it is present in molasses. An aqueous solution of this sugar, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. In consequence of its effect on polarized light, which is the opposite of that of the cane sugar from which it is prepared, it has been named by the French chemists *invert sugar* (*sucre interverti*). A solution of cane sugar, like that of grape sugar, has a rotating power to the right. When it ferments, it is first changed into uncrystallizable sugar by the invertase of the yeast, according to the reaction:

$$C_{12}H_{22}O_{11} + H_2O = (C_6H_{12}O_6)_2$$

and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the levulose which remains behind on account of its fermenting more slowly than the dextrose which is simultaneously formed in the process of inversion.

Glucose is the liquid product of the hydrolysis of starch by diluted acids in the presence of moisture and heat. Formerly the conversion was accomplished by the use of sulphuric acid, the excess of which was subsequently removed by neutralization with milk of lime and crystallizing out the difficultly soluble calcium sulphate, enough of which remained in solution, however, to render the detection of glucose in honey or cane sugar syrup indirectly possible by testing for calcium sulphate. (For details, see *U. S. D.,* 19th ed., p. 1071.) The conversion at the present time is accomplished by the use of hydrochloric acid which is ultimately volatilized by raising the temperature in open vessels, so that modern glucose contains no calcium sulphate and the older tests for its detection therefore are not applicable. The straw or amber color of the crude product was formerly removed by bleaching with sulphur dioxide, which sometimes was allowed to remain in the finished product in appreciable amounts. As many state food laws specifically prohibit sulphur dioxide or sulphites in most food products in which glucose was largely used as an ingredient, the modern method of decolorizing it is analogous to that for cane sugar and consists in the use of animal charcoal filters. The composition of commercial glucose varies. Theoretically the reaction is as follows:

$$\underset{\text{Starch}}{C_6H_{10}O_5} + H_2O = \underset{\text{Dextrose}}{C_6H_{12}O_6}.$$

In practice, however, the reaction is much more complex. In the commercial glucose there is present, besides the dextrose which is the predominating constituent, maltose, and dextrin; the latter is the constituent that prevents glucose from crystallizing. Another carbohydrate, which is unfermentable, named *gallisin,* $C_{12}H_{24}O_{10}$, is also present in varying amounts.

Syrupy glucose is also known commercially as *corn syrup,* although a better name would be *starch syrup,* as it is only in the United States, where corn is the cheapest raw material, that it is made exclusively from corn starch. In Germany it is made from potato starch and it certainly would not be proper to term such a product "corn syrup."

On account of the preponderance of dextrose which is a powerful reducing sugar and directly capable of alcoholic fermentation glucose is much used in the industries where these properties are desirable as in brewing and in reducing indigo to its leuco derivative, indigo-white, in the dye vat. It is extensively used as an adulterant in dyewood extracts, sole leather, etc. It is a frequent ingredient in the manufacture of confectionery, jellies, etc. Formerly some discredit attached to its use in food products under the mistaken popular belief that its manufacture was in some way connected with that of glue. The question of its healthfulness is no longer in doubt for when properly made and free from impurities it may be considered as a predigested form of starch.

It is theoretically possible, but not economically practicable at present, to make glucose not only from starch but also from any carbohydrate having the same formula, as cellulose (saw-dust).

Glucose is not so sweet as cane sugar and is more slowly soluble in cold water. Paul (*Chem. Ztg.*, 1921, xlv, 705) gives the sweetening power, as compared to sucrose as unity, of dextrose 0.52, levulose 1.03, lactose 0.28.

Description and Physical Properties.—"A colorless or yellowish, thick, syrupy liquid. It is odorless, or nearly so, and has a sweet taste. Glucose is very soluble in water, but is sparingly soluble in alcohol. Add a few drops of an aqueous solution of Glucose (1 in 20) to 5 cc. of hot alkaline cupric tartrate T.S.; a copious red precipitate of cuprous oxide is produced (*distinction from sucrose*).

"Introduce about 0.5 Gm. of Glucose into a wide-mouthed, tared weighing-bottle, weigh accurately, add 2 cc. of distilled water, evaporate at about 70° C., and dry the residue to constant weight at 90° C.; the loss in weight of the Glucose does not exceed 21 per cent (*water*). Ash: not more than 0.5 per cent. A solution of 5 Gm. of Glucose in 15 cc. of distilled water, mixed with 5 drops of phenolphthalein T.S., requires not more than 0.6 cc. of tenth-normal sodium hydroxide to produce a pink color (*free acid*). Dissolve about 2 Gm. of Glucose in 50 cc. of distilled water, boil the solution for one minute, and cool; the addition of one drop of tenth-normal iodine to this solution produces no blue color (*starch*). On now adding a few drops of starch T.S. to the solution, a blue color is produced (*limit of sulphur dioxide*). An aqueous solution of Glucose meets the requirements of the test for *heavy metals*. If the solution of Glucose is not colorless, comparison must be made with 10 cc. of the same solution, to which a volume of distilled water, equal to that of the hydrogen sulphide T.S. has been added. Dissolve 1.5 Gm. of Glucose in 5 cc. of distilled water, add 5 cc. of diluted sulphuric acid and 1 cc. of bromine T.S., and heat for five minutes on a water bath. Then add 0.5 Gm. of potassium iodide and 5 drops of stannous chloride T.S., cool and test the solution for *arsenic*. The stain, if any, is not greater than that produced in a test made with the same quantities of the reagents and 2 cc. of the standard arsenic test solution." *U. S.*

"A very viscous syrup, almost colorless. No odor; taste sweetish. Freely soluble in *water*, the solution being dextrorotatory and yielding a red precipitate when warmed with *solution of potassio-cupric tartrate.* 2 grammes dried at 100° C. in a thin film in a flat-bottomed dish do not lose more than 0.4 gramme (limit of moisture). When 10 grammes are dissolved in 100 millilitres of *water,* to which 10 millilitres of *N/10 solution of iodine* have previously been added, on shaking the mixture and immediately titrating with *N/10 solution of sodium thiosulphate,* not less than 6.8 millilitres of the latter solution are required for decolorisation (limit of sulphites). *Arsenic limit* 2 parts per million. Ash not more than 0.5 per cent." *Br.*

Uses.—For description of the intravenous uses of glucose see under *Dextrose.* The syrupy glucose is used in medicine for three purposes: First, as a cheap substitute for dextrose for oral or rectal administration; secondly, for its local dehydrating effect, and thirdly, as a pharmaceutical agent. In cases of *gastric ulcer* or other conditions in which it is undesirable to administer food by the stomach, rectal enemata of six to eight fluidounces (180–240 cc.) of a ten per cent. solution of glucose, every four hours, is often of assistance in aiding the maintenance of the nutritive condition. In *acidosis,* especially that type seen after prolonged *anesthesia,* the administration of large amounts of carbohydrates usually exercises a most beneficial action. The administration of glucose immediately before the production of anesthesia has been highly recommended as a preventative for vomiting, especially in children. (See *B. M. J.*, 1911, ii, p. 505.)

According to S. Meslach, glucose, when given in doses of from six to six and a half ounces per day in the form of the concentrated syrup, acts as a powerful diuretic, and is very useful in the treatment of *cardiac dropsy.* If the kidneys be healthy, the glucose is said not to appear in the urine. The celebrated grape cure of Europe is said to act by virtue of the dextrose in the grape.

Locally glucose has been used for its dehydrating effect, especially in the treatment of gun-shot wounds. For this purpose gauze may be saturated with solutions of glucose, either with or without the addition of some antiseptic, and placed over the wounds. It is claimed that this treatment encourages the flow of lymph and thereby tends to diminish the severity of infection. (See *L. L.*, 1915, i, p. 851.) Pharmaceutically glucose is used in solid extracts and other preparations where a uniform, moist consistence is desired, and as a diluent.

Off. Prep.—Used in making extracts U. S. P. and N. F., and in Br. Pharm. for pill masses. Ferri Carbonas Saccharatus, *Br.;* Ferri Phosphas Saccharatus, *Br.;* Mistura Ferri Composita, *Br.;* Syrupus Ferri Iodidi, *Br.;* Syrupus Glucosi, *Br.*

GLUSIDUM. U. S., Br.

GLUSIDE Glusid. [Benzosulphinidum, U. S. P. IX, Saccharin]

"The anhydride [$C_6H_4.CO.SO_2.NH$ 1:2] of ortho-sulphamide-benzoic acid." *U. S.* "Gluside, or benzoic sulphinide, $C_7H_5NSO_3$, the anhydride of orthosulphamidobenzoic acid, may be prepared from toluene." *Br.*

Neo-Saccharin; Glucusimide; Benzoyl-Sulphonicimide; Glukusin; Saccharine, *Fr. Cod.*; Sulfimide Benzoique, Sucre d'Houille, *Fr.*; Saccharinum, *P. G.*; Benzoesauresulfimid, Saccharol, Toluolsuss, Zuckerin, *G.*; Saccarina, *Sp.*

Preparation.—This artificial sweetening substance, which is known commonly as "saccharin," is made from toluene by first forming the ortho-sulphonic acid $C_6H_4\left\{\begin{matrix}SO_3H\\CH_3\end{matrix}\right.$; from this the sulphamide $C_6H_4\left\{\begin{matrix}SO_2NH_2\\CH_3\end{matrix}\right.$; from this, by oxidation, the sulphamide-benzoic acid $C_6H_4\left\{\begin{matrix}SO_2NH_2\\COOH\end{matrix}\right.$, of which the anhydride is the official compound. When dissolved in alkaline hydroxide solutions the salt of the sulphamide-benzoic acid is formed as $C_6H_4\left\{\begin{matrix}SO_2NH_2\\COONa\end{matrix}\right.$. (See *Sodii Benzosulphinidum.*)

Saccharin may be detected in sugar solutions by extracting with ether, evaporating and fusing the residue, which, if saccharin, will melt at about 220° C., and fused with potassium nitrate and sodium carbonate will show sulphuric acid. The weight of $BaSO_4$ obtained in this way from 100 Gm. of material multiplied by 0.785 will give the weight of saccharin extracted.

The aqueous solution of saccharin has a distinctly acid reaction and forms salts. Its most remarkable property is its sweet taste, which is approximately three hundred times more intense than that of sugar. (See Paul, *A. J. P.*, April, 1921.) The commercial product, according to Pope, frequently contains para-sulphamide-benzoic acid, from which impurity it can be freed by recrystallization, acetone being used as the solvent. Hefelman has furnished a process for assaying saccharin. (See *Proc. A. Ph. A.*, 1895, 701.) The difference in melting points of pure saccharin and para-sulphamide-benzoic acid is also used for distinguishing them; the former melts at 220° C. and the latter at 286.5° C. (*Ph. Cb.*, 1896, 279.)

Description and Physical Properties.—"White crystals, or a white, crystalline powder. It is odorless, or has a faint, aromatic odor. Gluside in aqueous solution is from 300 to 500 times sweeter than sucrose. One Gm. of Gluside is soluble in 290 cc. of water and in 31 cc. of alcohol, at 25° C. One Gm. is soluble in about 25 cc. of boiling water. It is slightly soluble in chloroform and in ether, and is easily dissolved by ammonia water, by solutions of alkali hydroxides, and by solutions of alkali bicarbonates with the evolution of carbon dioxide.

"The melting point of Gluside is not below 222° C. Pure Gluside melts at about 228° C. A saturated aqueous solution of Gluside is acid to litmus paper. Dissolve about 0.1 Gm. of Gluside in 5 cc. of an aqueous solution of sodium hydroxide (1 in 10), evaporate the solution to dryness, and gently fuse the residue over a small flame until ammonia is no longer evolved. Allow the residue to cool, dissolve in 20 cc. of distilled water, neutralize the solution with diluted hydrochloric acid, and filter; the addition of a drop of ferric chloride T.S. to the filtrate produces a violet color. Mix about 0.02 Gm. of Gluside with about twice its weight of resorcinol, add 10 drops of sulphuric acid, and heat the mixture over a small flame until it acquires a dark green color. Allow it to cool, add 10 cc. of distilled water, and an excess of sodium hydroxide T.S.; a fluorescent-green liquid results.

"Ash: not more than 0.5 per cent. A solution of 0.2 Gm. of Gluside in 10 cc. of sulphuric acid, kept at a temperature of from 48° to 50° C. on a water bath, develops no darker color than light brown within ten minutes (*readily carbonizable substances*). A solution of 0.2 Gm. of Gluside in 5 cc. of sodium hydroxide T.S. is clear, and, when mixed with 5 cc. of alkaline cupric tartrate T.S., does not deposit cuprous oxide on heating (*glucose, lactose*). Add ferric chloride T.S., drop by drop, to 10 cc. of a hot, saturated aqueous solution of Gluside; no precipitate or violet color appears (*benzoic or salicylic acid*). No odor of ammonia is noticeable on warming 0.5 Gm. of Gluside with about 1 Gm. of magnesium oxide and 10 cc. of distilled water (*ammonium compounds*)." *U. S.*

"A white crystalline powder. Taste in dilute solution, intensely sweet. Soluble in 400 parts of *water*, and in 38 parts of *alcohol* (90 per cent.); soluble also in solutions of alkalies and of alkaline carbonates, the neutral sodium salt being known as 'soluble gluside.' Completely soluble in 12 parts of *acetone*. 1 gramme heated for four hours on a water-bath with 10 millilitres of a mixture of 4 volumes of *sulphuric acid* and 3 volumes of *water* completely dissolves, and when the solution is diluted with an equal volume of *water* and allowed to stand for twenty-four hours no crystals separate. Gently warmed for a short time with *sulphuric acid* no blackening occurs. Ash not more than 0.5 per cent." *Br.*

Commercial saccharin sometimes contains impurities derived from the manufacture. Among these may be found sulphamido-benzoic acids, toluene sulphonamides, etc. P. V. McKil (*J. Soc. Chem. Ind.*, 1921, xl, 150-T) discusses these impurities and the methods for their detection.

Saccharin may be readily estimated in food products, etc., with no danger of emulsification, by the following method: 100 cc. of the liquid under examination are added to 10 to 15 cc. of a 10 per cent. solution of tannic acid, and then lead subacetate solution is added. Filter and acidify an aliquot portion of the filtrate with phosphoric acid and extract by shaking out with a mixture of ether and petroleum ether.

Upon evaporating the ethereal mixture the saccharin is left in a pure state.

Saccharin may be determined quantitatively by the method of Richmond and Hill (*C. D.,* 1918, xc, 851 and 913) which depends upon the liberation of ammonia under specified conditions.

Uses.—Taken internally saccharin is rapidly absorbed and eliminated unchanged through the kidneys. It is almost free from general physiological activities. Mosso and Aducco have given seventy-five grains to a man without sensible effect, and 600 grains to a dog within ten days without any change in the weight, general health or metabolism as indicated by urinalysis. On the other hand it has a slight local irritant action and according to the referee board of the U. S. Bureau of Chemistry, doses of more than 0.3 Gm. per day are liable, if used over periods of time, to impair digestion. The statement sometimes made that it is irritant to the kidneys seems to lack positive confirmation. Its use in medicine is purely as a sweetening agent in those diseases such as *diabetes* and *obesity* where sugar is contraindicated. The assertion that saccharin increases the catalase of the blood has been disproven by Stehle (*J. Bi. Chem.,* 1919, xxxix, 39) and by Becht (*J. P. Ex. T.,* 1920, xvi, 155).

The sweetening power of gluside as compared to sugar has been shown by Paul (*J. Soc. Chem. Ind.,* 1921, xl, 33-R) to vary with the degree of concentration; thus in relatively strong solutions —corresponding to about 10 per cent. of sugar— the sweetening effect of the sodium salt of gluside is about 200 times that of sugar, on dilution the gluside solution retains its sweetness better, so that when compared to a 2 per cent. solution of sugar the soluble gluside has approximately 700 times the sweetening power of sugar. It has also been widely employed in preserves, canned foods, and beverages for the same purpose, but this latter act, according to the decision of the U. S. Department of Agriculture, constitutes adulteration of the food, as it allows the omission of cane sugar.

Dose, three to five grains (0.2–0.32 Gm.).

GLUSIDUM SOLUBILE. U. S.

SOLUBLE GLUSIDE Glusid. Sol. [Sodii Benzosulphinidum, U. S. P. IX, Soluble Saccharin]

“ $C_6H_4.CO.SO_2.NNa.2H_2O$.” *U. S.*

For the chemistry of benzosulphinide, see under *Glusidum.*

This salt may be prepared by the careful neutralization of sodium carbonate solution with benzosulphinide or so-called insoluble saccharin, and subsequent concentration of the solution and crystallization of the salt.

Description and Physical Properties.— “ Colorless crystals or a white, crystalline powder. It is odorless or has a faint, aromatic odor, and an intensely sweet taste even in dilute solutions, being from 300 to 500 times sweeter than sucrose. It is somewhat efflorescent. One Gm. of Soluble Gluside is soluble in 1.2 cc. of water, and in about 50 cc. of alcohol at 25° C.

“ Soluble Gluside responds to the identity tests with ferric chloride and with resorcinol under *Glusidum.* When Soluble Gluside is incinerated, a residue remains consisting chiefly of sodium sulphate, which imparts a yellowish color to a non-luminous flame. On mixing 10 cc. of its aqueous solution (1 in 10) with 1 cc. of hydrochloric acid, a crystalline precipitate of gluside is produced.

“An aqueous solution of Soluble Gluside (1 in 10) is neutral or only slightly alkaline to litmus paper, but produces no red color with phenolphthalein T.S. Add 3 drops of ferric chloride T.S. to 10 cc. of an aqueous solution of Soluble Gluside (1 in 20) previously acidulated with 5 drops of acetic acid; no precipitate or violet color is produced (*benzoate* or *salicylate*). Soluble Gluside complies with the tests for *ammonium compounds, readily carbonizable substances, and for glucose and lactose,* under *Glusidum.*” *U. S.*

Uses.—Sodium benzosulphinide is useful solely as a sweetening agent in those conditions, such as *diabetes, gout, obesity,* etc., in which sugar is objectionable. It has the advantage over the anhydride (see *Benzosulphinidum*) of being more freely soluble.

Dose, one-fourth to three grains (0.016–0.2 Gm.).

GLYCERINUM. U. S., Br.

GLYCERIN Glycerin. [Glycerol]

“ Glycerin contains not less than 95 per cent. of $CH_2OH.CHOH.CH_2OH$.” *U. S.* “ Glycerin, or glycerol, is a trihydric alcohol, $C_3H_5(OH)_3$, associated with a small percentage of water; it is obtained by the hydrolysis of fats and fixed oils by means of alkalies or of superheated steam.” *Br.*

Glycerina, *U. S.* 1870; Glycerine; Glycerine officinale, *Fr. Cod.;* Glycerinum, *P. G.;* Glycerin, Glyceryloxyhydrat, Oelsüss, Scheelesches Süss, *G.;* Glicerina, *It., Sp.*

Glycerin was discovered in 1789 by Scheele, by whom it was called the *sweet principle of oils.* It is produced not only during the saponification of the fats and oils by lead oxide in forming lead plaster, but also during the same process when affected by potassium and sodium hydroxides in the manufacture of soap, the alkalies uniting with the fatty acids and setting the glycerin free. Soap-maker’s waste is an abundant source of glycerin; but when thus obtained it is apt to have more or less odor, which even percolation through animal charcoal does not always remove.

The recovery of glycerin from spent soap lyes is accomplished by treatment with lime or ferrous sulphate and subsequent acidulation, clarification with aluminum sulphate, filtration and concentration in a vacuum still. The crude glycerin thus obtained represents about 90 per cent. of glycerin; it is used for industrial purposes in its crude form or may be purified by distillation.

Glycerin is also prepared by the direct hydrolysis of fat. In the so-called "autoclave method" this is accomplished by heating with zinc oxide and zinc dust under pressure of 6 atmospheres. The "Twitchell method" employs a "reactive" which is formed by treating a mixture of an aromatic compound (such as benzol or naphthalene) and a fatty acid (as stearic) with concentrated sulphuric acid. The compound formed is soluble in both water and oil and possesses marked emulsifying and hydrolizing power. The fat to be decomposed is first treated with sulphuric acid to remove albuminous and pectinous substances, and is then boiled for some time with from 0.4 to 0.5 per cent. of the "reactive." The resulting solution of glycerin in water is treated in succession with barium carbonate, barium hydroxide and ammonium sulphate filtered and evaporated to 28° Baumé. The crude glycerin is purified by distillation (see *Ap. Ztg.*, 1915, p. 500).

In America the purification of glycerin by distillation is frequently accomplished according to Scott's patent in a high vacuum with superheated steam. A new method called "multiple-effect distillation" uses the same current of steam for several stills and condensers. In this method the glycerin is first warmed and then sprayed through steam; the mixed glycerin and water vapors pass into a condenser whose temperature is so regulated that only the glycerin vapor condenses while the water vapor passes to the next still to be again mixed with glycerin. Glycerin is now being made by synthetic processes. A recent English patent starts with propylene which is first converted into dichlor-propane, which subsequently is converted into allyl chloride and then into trichlor-propane, $CH_2Cl.CHCl.CH_2Cl$, which when heated with water to 150° C. splits up into glycerin and water according to the following reaction:

$$\underset{\text{Trichlor-propane}}{CH_2Cl.CHCl.CH_2Cl} + 3H_2O = \underset{\text{Glycerin}}{CH_2OH.CHOH.CH_2OH} + 3HCl.$$

Glycerin is always produced to a limited extent during alcoholic fermentation, the amount of glycerin present in certain liquids produced originally by alcoholic fermentation—as wine, vinegar, etc.—being so constant as to constitute a valuable aid in proving identification or freedom from adulteration. Various attempts have been made to economically recover the glycerin from the waste liquors of distilleries but without practical results as yet, although there is little doubt of its ultimate accomplishment. During the World War the high price of glycerin led to further researches along this line and special methods of controlling and augmenting the glycerin yield during alcoholic fermentation resulted in obtaining yields as high as 21.3 grammes of glycerin for each 100 grammes of sugar taken. It is said that the Germans used one of these fermentation methods for their supply of glycerin at that time. (See *J. I. E. C.*, 1919, xi, 842 and *J. Soc. Chem. Ind.*, 1919.)

Description and Physical Properties.—"A clear, colorless, syrupy liquid, having a sweet taste. It has not more than a slight, characteristic odor which is neither harsh nor disagreeable. When exposed to the air, it absorbs moisture. Glycerin is miscible with water and with alcohol. It is insoluble in chloroform, ether, benzene, petroleum benzin, carbon disulphide, and in fixed or volatile oils. Heat a few drops of Glycerin with about 0.5 Gm. of potassium bisulphate: pungent vapors of acrolein are evolved.

"Glycerin is colorless when viewed transversely in a tube of colorless glass about 30 mm. in diameter, held in a vertical position. Specific gravity: not below 1.249 at 25° C. An aqueous solution of Glycerin (1 in 20) is neutral to litmus paper. Heat 50 Gm. of Glycerin in an open, shallow, 100 cc. porcelain dish until it ignites, and allow it to burn without further application of heat in a place free from draught: not more than 0.015 per cent. of carbonaceous and mineral residue remains. Ignite this residue at a low red heat, until combustion is complete: not more than 0.007 per cent. of mineral residue remains. Place 5 cc. of Glycerin in a 50 cc. glass-stoppered cylinder, add 5 cc. of sulphuric acid, and shake vigorously for one minute: the liquid does not become darker than yellow on standing for one hour (*readily carbonizable substances*). Mix 50 Gm. of Glycerin with 50 cc. of freshly boiled distilled water and 5 cc. of half-normal sodium hydroxide, boil the mixture for five minutes, cool, and titrate the excess of alkali with half-normal hydrochloric acid, using phenolphthalein T.S. as indicator: not less than 4 cc. of half-normal hydrochloric acid is required (*fatty acids and esters*). Ten cc. portions of an aqueous solution of Glycerin (1 in 10) remain clear on the addition of 0.5 cc. of calcium chloride T.S. (*oxalate*), or of 0.5 cc. of silver nitrate T.S. (*chloride*), and no turbidity is produced in 10 cc. of the solution, previously treated with three drops of dilute hydrochloric acid, by the addition of five drops of barium chloride T.S. (*sulphate*). An aqueous solution of Glycerin meets the requirements of the test for *heavy metals,* and the test for *arsenic.* A mixture of 5 cc. of Glycerin and 5 cc. of an aqueous solution of potassium hydroxide (1 in 10) does not become yellow when kept for five minutes at 60° C. (*acrolein, glucose*) or emit an odor of ammonia (*ammonium compounds*).

"Preserve in well-closed containers." *U. S.*

"A clear, colorless, hygroscopic, syrupy liquid. No odor; taste sweet, followed by a sensation of warmth. Miscible with *water,* and with *alcohol* (90 per cent.). Insoluble in *ether,* in *chloroform,* and in fixed oils. Specific gravity 1.260. When strongly heated decomposes with evolution of irritating vapors. Neutral to *litmus.* An aqueous solution (1 in 10) yields no characteristic *reactions* for ammonium, chlorides, or sulphates. Assumes, when heated, not more than a faint yellow but no pink coloration, and yields not more than a very slight charred residue and no odor of burnt sugar (absence of sugar). Undergoes no darkening in color when mixed with an equal volume of *solution of ammonia* and a few drops of *solution of silver nitrate,* the mixture being kept protected from light and the observation being made after a lapse of five minutes (absence of formic acid, acrolein). Gently warmed with an equal volume of *diluted sulphuric acid,* the mixture being vigorously shaken, not more than a faint odor is noticeable (absence of fatty acids). Shaken with an equal volume of *sulphuric acid,* the mixture being kept cool, not more than a very slight straw coloration is produced (absence of extraneous organic matter). A mixture of 10 millilitres of Glycerin with 40 millilitres of *water,* 1 drop of *solution of ammonia,* and 1 drop of *solution of tannic acid,* assumes not more than a faint and transient pink or purple coloration (limit of iron). When tested for lead according to the quantitative test described in Appendix V, but using 10 grammes in each Nessler glass, no difference is observed upon the addition of the *solution of sodium sulphide* to one of the solutions (absence of lead). When the foregoing test is repeated, but omitting the addition of *solution of ammonia* and of *solution of potassium cyanide,* and adding to each solution 1 millilitre of *diluted hydrochloric acid,* no difference in color is observed upon the addition of *solution of hydrogen sulphide* to one of the solutions (absence of copper). *Arsenic limit* 4 parts per million. No appreciable ash." *Br.*

When exposed to the air glycerin gradually absorbs moisture. As already stated, though decomposed by a high heat in its unmixed state, yet with water under pressure it is volatilizable unchanged at a temperature between 204.4° and 260° C. Cooled down rapidly, it only becomes more viscid, without congealing, even when a temperature of –40° C. is attained; but, if kept for some time at a temperature of about 0° C., it gradually forms hard but deliquescent crystals, which melt only at about 22° C. This fact is now utilized as a means of concentrating and purifying glycerin.

According to G. F. Wilson, glycerin, when of the density 1.24, contains 94 per cent. of anhydrous glycerin; when of the density 1.26, 98 per cent. A table by Wilhelm Lenz (*Zeit. An. Chem.,* 1880), showing the percentage of absolute glycerin in mixtures of glycerin and water, which was obtained by a quantitative determination of the carbon in the various dilutions by ultimate analysis, will be found in the U. S. D., 15th ed., p. 712. The table below, by W. W. J. Nicol of England, has been constructed after careful determinations, aided by A. B. Lyons's data on expansion of glycerin solutions. (*Ph. Era,* 1888.)

Glycerin has been formed artificially from tribromallyl, by Wurtz, and from trichlorhydrin, by Friedel and Silva.

Glycerin possesses extensive powers as a solvent, and is an excellent excipient for many medicinal substances. It dissolves bromine and iodine, sulphur iodide, potassium and sodium chlorides, the fixed alkalies, some of the alkaline earths (it increases the solubility of lime in water), and a large number of neutral salts. It is a good solvent of pepsin, and is used for the extraction of this principle from the mucus of the stomach. Glycerin, next to alcohol, is the best solvent of iodine. Iodine and potassium iodide, when dissolved in it, form *iodized glycerin,* the medicinal applications of which are given under iodine. (See *Iodum.*) It combines with a number of alkalies, and also with sulphuric acid.

Glycerin does not evaporate rapidly when exposed to the air, although it vaporizes to such an extent as to make it necessary to avoid a water-bath temperature to the concentrated article during its quantitative estimation. It can not be distilled without decomposition, unless in the presence of water or steam. When decomposed by heat, it emits extremely irritating vapors of acrolein. At a full red heat it takes fire, and burns with a blue flame. In consequence of the high temperature required for its volatilization, it has been proposed to use it for an evaporating bath, in which a heat beyond that of boiling water is required.

The solvent properties as well as agreeable taste and permanent consistence of glycerin render it very useful as a menstruum in pharmacy, and a class of preparations consisting of medicinal substances dissolved in it has come into extensive use. The British Pharm. (1885) adopted such a class, under the name of *Glycerina,* or *glycerins.* The title "glycerines" is not now available because the termination "ine" is reserved for alkaloids, while the term *glyceroles,* adopted from the French, is objectionable, as the termination "ole" has been used to designate certain proximate principles; but the U. S. Pharmacopœia title, *Glycerita,* or *glycerites,* is satisfactory. (See *Glycerita.*) G. M. Beringer proposed a class of preparations made with glycerin. (See *Fluidglycerates,* in the National Formulary.)

Impurities and Tests.—Glycerin is occasionally deficient in density and consistency. According to Dalpiaz, it is sometimes perfectly colorless from being bleached by chlorine, when it is apt to contain calcium chloride, as well as free chlorine. The latter may be detected by rendering the suspected sample slightly blue by a few drops of an acid solution of indigo in sulphuric acid, when, if free chlorine be present the blue color will disappear. Starch paste containing a little potassium iodide is a better test, however; if a blue color appears when this is added to glycerin, free chlorine is indicated. (See U. S. P. and Br. tests.)

Glycerin, on account of its high price during the World War, was substituted industrially by a number of cheaper products, among which was a commercial invert sugar of about the same consistency as glycerin, but slightly higher in specific gravity. (Jos. Feil, *J. A. Ph. A.,* 1914, 1648.)

One of the more recent substitutes for glycerin is ethylene glycol, $(CH_2OH)_2$, which resembles glycerin more closely than any other substance that has been proposed. *Glycol* is prepared from acetylene. It is more volatile and less viscous than glycerin; boiling point, 197°; density at 0° C., 1.125; index of refraction at 20° C., 1.4723. The solubility in water, alcohol, and ether is perfectly analogous to that of glycerin. The Denigès reaction (heating with bromine water, addition, after cooling, of condensed sulphuric acid and a 50 per cent. guaiacol solution, blue coloration, violet in heating) gives a positive result with glycerin and glycol, but the latter does not give the Neuberg-Mendel reaction (boiling with a slightly alkaline hypochlorite solution, addition of olein and hydrochloric acid, boiling to violet or green coloration). The two substances can also be distinguished by the index of refraction. When this constant is less than 1.428 the material is surely glycol, and when more than 1.464, glycerin. (*Chem. News,* 1921, cxxii, 239.)

In the quantitative determination of glycerin when in a state of purity, the specific gravity test is important. In crude glycerin and in other products where it may only exist in small amounts, various processes are in use. One of the best known of these is the Hehner, Richardson, Jaffe, method, which depends upon the oxidation of potassium dichromate; or it may be determined by its acetylization with acetic anhydride, the so-called acetin method.

The official method of the A. O. A. C. given in Bulletin No. 107, of the Bureau of Chemistry of the U. S. Department of Agriculture, is used for the determination of glycerin in wines, etc. Leroy Forman (*J. A. Ph. A.,* 1914, 1644) shows this method to give low results when applied to the analysis of tablets, confections, etc. He overcomes this difficulty by the use of milk of lime during the evaporation.

Uses.—Glycerin is valuable as a vehicle not only because of the solvent properties, but because of its sweetness, having the great advantage over syrup of non-fermentability. It has been recommended as a preservative for galenicals in which alcohol is undesirable, but its antiseptic action is so slight that its usefulness for this purpose is very questionable. Ruediger (*J. A. M. A.,* 1915, lxiv, 1529) has found that although certain bacteria are more susceptible, it requires four days' exposure for 50 per cent. glycerin to destroy non-sporulating organisms and that the spore-forming bacteria are not destroyed by fifteen days' exposure. Goodrich (*P. J.,* 1917, xcviii, 453) states that 50 per cent. glycerin is scarcely more disinfectant than pure water. When injected intravenously in large doses it is capable of causing severe and even fatal poisoning, but the amount required to produce this effect is so large as to suggest that it acts rather by altering the physical condition of the blood than by any true physiological properties. Faust and Tallquist (*A. E. P. P.,* 1907, lvii, p. 366), on the theory that the hemolytic poison in *pernicious anemia* is oleic acid, suggested the use of glycerin as a remedy and the theory has received some clinical confirmation. Aside from its pharmaceutical use, the most important medical value of glycerin is as a local remedy. Pure glycerin because of its hygroscopic properties is locally irritating to mucous membranes. It is serviceable, however, probably through dehydrating influence as a local application over *furuncles* and similar local inflammatory conditions and has even been recommended in burns and wounds. In a diluted form it is often of great value for its emollient properties in various forms of *skin diseases.*

It is extensively employed in habitual *constipation* in the form of suppositories. (See *Suppositoria Glycerini*).

To collodion it gives a valuable plasticity. Incorporated in very small proportion with extracts and pills, it keeps them soft and free from mouldiness. Glycerin may be used in the form of an ointment, and is also used in the menstruum of official extracts, fluidextracts, glycerites, infusions, syrups, tinctures, etc., and in making pills.

Dose, one fluidrachm (3.75 cc.).

Off. Prep.—Gelatinum Glycerinatum, *U. S.;* Suppositoria Glycerini, *U. S., Br.;* Cataplasma Kaolini, *N. F.;* Glyceritum Amyli, *U. S.;* Glyceritum Boroglycerini, *U. S.;* Suppositoria Boroglycerini, *N. F.;* and as solvent and preservative in Glycerites, Fluidglycerates, Fluidextracts and Tinctures.

GLYCERINUM ALUMINIS. Br.

GLYCERIN OF ALUM

Glycéré d'Alun, *Fr.;* Alaun-Glycerit, *G.*

"Purified Alum, 20.0 *grammes;* Distilled Water, 7.5 *millilitres;* Glycerin sufficient to produce 120.0 *millilitres.* Powder the Alum, triturate with the Distilled Water and Glycerin until solution is effected, warming slightly if necessary; set aside; pour off the clear liquid from any deposit that may be formed." *Br.*

This has an astringency similar to glycerite of tannin without the tendency to soil the linen or blacken in contact with iron, but it is much more irritating.

GLYCERINUM BORACIS. Br.

GLYCERIN OF BORAX

Glycéré de Borax, *Fr.;* Borax-Glycerit, *G.*

"Purified Borax, 20 *grammes;* Glycerin, 120 *millilitres.* Powder the Borax, and triturate with the Glycerin in a warmed mortar until solution is effected." *Br.*

The demulcent properties and sweet taste of this preparation render it a useful and convenient method of applying borax to the infantile *thrush* and other forms of sore mouth in children.

GLYCERINUM PEPSINI. Br.

GLYCERIN OF PEPSIN

Glycéré de Pepsine, *Fr.;* Pepsin-Glycerit, *G.*

"Pepsin, 100.0 *grammes;* Hydrochloric Acid, 11.5 *millilitres;* Glycerin, 600.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Mix the Hydrochloric Acid, Glycerin, and two hundred and sixty *millilitres* of the Distilled Water; add the Pepsin; dissolve; add sufficient Distilled Water to produce the required volume; set aside for twenty minutes; filter. Ten cc. of this preparation contain 1 gramme of Pepsin; 1 fluidrachm contains about 5.5 grains." *Br.*

This preparation is practically identical with the glycerite of pepsin of the National Formulary. (See Part III.)

Dose, one fluidrachm (3.75 cc.), equivalent to five grains of pepsin.

GLYCERINUM PLUMBI SUBACETATIS. Br.

GLYCERIN OF SUBACETATE OF LEAD

Glycéré de Sousacétate de Plomb, *Fr.;* Bleiessigglycerit, *G.*

"Strong Solution of Lead Subacetate, 500 *millilitres;* Glycerin, 500 *millilitres;* Distilled Water, a sufficient quantity. Evaporate the Strong Solution of Lead Subacetate to dryness on a water-bath; add the Glycerin; warm gently until dissolved; cool; add Distilled Water till the specific gravity of the mixture is 1.48; filter, if necessary." *Br.*

This glycerite originated with Balmanno Squire of London, but the process made official in the Br. Pharm. (1898) was that recommended by R. W. Parker. (See *A. J. P.,* 1886, 296.) The official process (1914) is a simpler one and more convenient for the pharmacist. It is a powerful sedative astringent, and may be employed as a local application in external inflammation.

GLYCERINUM TRAGACANTHÆ. Br.

GLYCERIN OF TRAGACANTH

Glycéré de Gomme Adragante, *Fr.;* Traganth-Glycerit, *G.*

"Tragacanth, in powder, 10 *grammes;* Glycerin, 30 *millilitres;* Distilled Water, 10 *millilitres.* Mix the Glycerin with the Tragacanth; add the Distilled Water; triturate until a homogeneous paste is produced." *Br.*

This preparation has been introduced into the British Pharmacopœia mainly to serve as an excipient for pills.

GLYCERITA.

GLYCERITES

Glycerina, *Br.;* Glycerins; Glycerata, Glycerolata, Glycerols; Glycérés, *Fr. Cod.;* Glycérats, Glycérolés, *Fr.;* Glycerit, Glycerolat, *G.*

These are solutions of medicinal substances in glycerin. The U. S. name is certainly much better than the British name glycerin (*Glycerinum*) for this does not distinguish a *class* of preparations from the *solvent* used in making them. (See under *Glycerinum.*)

Glycerin has valuable properties as a solvent and vehicle for medicinal substances. Such are its not unpleasant taste and bland character, its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution otherwise insoluble substances so frequently found in infusions and decoctions, and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive to organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin, resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Its hygroscopic quality, however, gives it irritating properties under certain conditions.

GLYCERITUM ACIDI TANNICI. U. S. (Br.)

GLYCERITE OF TANNIC ACID Glycer. Acid. Tann.
[Glycerite of Tannin]

Glycerinum Acidi Tannici, *Br.;* Glycerin of Tannic Acid (of Tannin); Glycéré de Tanin, *Fr. Cod.;* Glycérole de Tannin; Glycérine tannique, *Fr.;* Tannin-Glycerit, Tannin-Glycerol, *G.*

"Tannic Acid, 20 Gm.; Sodium Citrate, 1 Gm.; Glycerin, 79 Gm.; to make 100 Gm. Weigh the glycerin into a tared, wide-mouthed bottle, having a capacity of 125 cc. Suspend the tannic acid and sodium citrate, in a gauze bag, in the glycerin, place the bottle and contents in a water bath containing boiling water and continue the heat, stirring the mixture occasionally until solution results." *U. S.*

"Tannic Acid, 20 *grammes;* Glycerin, sufficient to produce 100 *millilitres.* Triturate the Tannic Acid with the Glycerin in a warmed mortar until solution is effected." *Br.*

The U. S. preparation is a 20 per cent. solution by weight; the strength of the British preparation is somewhat weaker, being a 20 per cent. solution by measure. Glycerin is the only solvent that will enable a stable solution of tannic acid to be made, that may be readily diluted with water to any desired strength.

This preparation may be used, both internally and externally, for most of the purposes to which tannic acid is applied. On the whole, it is the most useful preparation of tannic acid for external use; as circumstances require the official strength may be altered by direction of the physician; a very concentrated solution, two parts of glycerin to one of tannin, may be made by the aid of a moderate heat. This applied daily to nipples, during the later months of pregnancy, will usually prevent the occurrence of *sore nipples* during suckling.

Dose, from ten to forty minims (0.65–2.6 cc.). (See *Acidum Tannicum.*)

GLYCERITUM AMYLI. U. S. (Br.)

GLYCERITE OF STARCH Glycer. Amyl.

Glycerinum Amyli, *Br.;* Glycerin of Starch, Glycamyl, Plasma; Glycéré d'Amidon, *Fr. Cod.;* Glycérate simple (d'Amidon), *Fr.;* Unguentum Glycerini, *P. G.;* Glycerinsalbe, Stärke-Glycerit, *G.;* Glicerolato di amido, *It.;* Glicerolado de almidon, *Sp.*

"Starch, 10 Gm.; Water, 20 cc.; Glycerin, 70 cc. Triturate the starch with the water until a homogeneous mixture is produced. Then gradually add this to the glycerin, contained in a porcelain dish, and heated to about 140° C. Continue the heat, keeping it below 144° C., constantly stirring the mixture until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers." *U. S.*

"Starch, 20 *grammes;* Glycerin, 130 *millilitres;* Distilled Water, 30 *millilitres.* Mix; heat, stirring constantly, until a translucent jelly is formed." *Br.*

These preparations are used as a substitute for ointments, the emollient and demulcent properties of which they possess, without their inconvenience, whether used simply, or as a vehicle for other substances to be employed locally. J. H. Pearson (*P. J.*, 1897, 201) recommends the addition of one grain of powdered tragacanth to the ounce of finished product, to prevent the separation of the glycerin and water from the mass, on standing.

GLYCERITUM BOROGLYCERINI. U. S. (Br.)

GLYCERITE OF BOROGLYCERIN Glycer. Boroglyc.
[Solution of Boroglyceride]

Glycerinum Acidi Borici, *Br.;* Glycerin of Boric Acid; Glycerite of Glyceryl Borate; Glycéré de boroglycéride, *Fr.;* Boroglyceridlösung, *G.*

"Boric Acid, in fine powder, 310 Gm.; Glycerin, a sufficient quantity to make 1000 Gm. Heat 460 Gm. of glycerin in a tared porcelain dish on a sand bath to a temperature between 140° and 150° C., and add the boric acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface until the mixture has been reduced to 500 Gm., then add 500 Gm. of glycerin, mix thoroughly, and immediately transfer the product to bottles and stopper them tightly." *U. S.*

"Boric Acid, 300 *grammes;* Glycerin, sufficient to produce 1000 *grammes.* Add the Boric Acid to four hundred and fifty *grammes* of the Glycerin, boil until dissolved, constantly stirring; evaporate at a temperature rising to but not exceeding 150° C. until the weight of the mixture has been reduced to five hundred grammes, the stirring being continued. Add sufficient Glycerin to produce the required weight; mix thoroughly." *Br.*

This solution was first introduced into the U. S. P. 1890 from the National Formulary. It is a thick, sweet, viscid, colorless liquid, and has the advantage of offering the antiseptic, boric acid, in a very soluble form as it is soluble in practically all proportions in water. It may be made more rapidly than by the above process if one ounce av. of boroglyceride be dissolved in one ounce av. of glycerin with the aid of a gentle heat. (See *Boroglyceride*, Part II.)

Off. Prep.—Suppositoria Boroglycerini, *N. F.*

GLYCERITUM PHENOLIS. U. S. (Br.)

GLYCERITE OF PHENOL Glycer. Phenol.
[Glycerite of Carbolic Acid]

Glycerinum Acidi Carbolici, *Br.;* Glycerin of Phenol; Glycérole d'Acide Phénique, Glycéré de Phenol, Glycérine Phénique, *Fr.;* Phenol-Glycerit, *G.;* Glycerina con acido fenico, *Sp.*

"Liquefied Phenol, 20 cc.; Sodium Citrate, 1 Gm.; Boiling Distilled Water, 1 cc.; Glycerin, 79 cc.; to make 100 cc. Dissolve the sodium citrate in 1 cc. of boiling distilled water, and add this solution to the mixture of glycerin and phenol, previously prepared." *U. S.*

"Phenol, 20 *grammes;* Glycerin, sufficient to produce 100 *millilitres.* Triturate the Phenol with the Glycerin in a warmed mortar until solution is effected." *Br.*

Uses.—For the uses of this preparation, see *Phenol.* The U. S. P. glycerite is a 20 per cent., by volume, solution of liquefied phenol; the British preparation is slightly stronger, being a 20 per cent., by volume, solution of crystallized phenol. It may be used internally or locally, and for both purposes should in general be diluted with water.

Dose, from five to ten minims (0.32–0.65 cc.).

GLYCYRRHIZA. U. S. (Br.)

GLYCYRRHIZA Glycyrrh. [Licorice Root]

"Glycyrrhiza is the dried rhizome and roots of *Glycyrrhiza glabra* Linné var. *typica* Regel et Herder, known in commerce as Spanish Licorice or of *Glycyrrhiza glabra* Linné var. *glandulifera* Regel et Herder known in commerce as Russian Licorice, or of other varieties of *Glycyrrhiza glabra* Linné yielding a yellow and sweet wood (Fam. *Leguminosæ*). Glycyrrhiza yields not more than 2.5 per cent. of acid-insoluble ash." *U. S.* "Liquorice Root is the peeled root and peeled subterranean stem of Glycyrrhiza glabra, *Linn.*, and other species of Glycyrrhiza." *Br.*

Glycyrrhizæ Radix, *Br.;* Radix Glycyrrhizæ Hispanicæ, Spanish Licorice Root; Liquiritiæ Radix, Réglisse, *Fr. Cod.;* Réglisse, Racine de Réglisse, Bois doux, Racine douce, *Fr.;* Radix Liquiritiæ, *P. G.;* Spanisches Süssholz, Spanische Süssholzwurzel, Süssholzwurzel, *G.;* Liquirizia, *It.;* Regaliz (Raiz de), Orozuz, Palo dulce, *Sp.*

Glycyrrhiza glabra, which yields Spanish Licorice, is a perennial herb whose underground portion consists of a slender branching rhizome bearing a number of delicate rootlets. The stems are herbaceous, erect, slightly branching, and usually four or five feet in height. The leaves are alternate, pinnate, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale-green color, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to six small kidney-shaped seeds. This plant grows best on sandy soil near streams, usually not being found more than fifty meters from a body of water. It is indigenous to southern Europe and southwestern Asia, and is cultivated in England, Germany, Spain, Italy and Austria and has been grown on an experimental scale in the United States. *Glycyrrhiza echinata,* the source of "Russian Licorice," is a native of southern Russia and Hungary but also occurs in the wild state in Italy, Sicily and other Mediterranean countries where it is also cultivated. Its subterranean portion consists of a fleshy, fusiform root, from which stems spring that attain a height of 5 to 6 feet. These are several-branched, the branches being cylindrical toward the base and angled toward their ends. The leaves are smooth, imparipinnate, with oblong-mucronate leaflets. The flowers are violet-colored and occur in short-stalked, axillary heads in the leaf axils. The fruit is an oval, pointed, spiny, one-seeded legume.

A comparatively small portion of the licorice imported into the United States is used by the drug industry, the greater bulk of the huge supply which is annually coming into our ports being consumed by the tobacco and confectionery trades and in fire extinguisher compounds. The root is collected alike from wild and cultivated plants, cleaned and variously prepared for the market. The Spanish variety is the most esteemed and usually comes in segments of variable length, in bundles, and as cut root, the first two grades being packed in covered or uncovered bales, the last, in bags. This variety has been frequently named after the country in which it is collected, a practice which has often been confusing to the purchaser. Most of the licorice designated as Italian, Turkish, Levant, Persian or Arabian has been found to be yielded by geographical varieties of *G. glabra.* It is shipped commonly from Smyrna, Haifa, the Spanish ports of Alicante, Barcelona and Seville, from Leghorn, Italy, Constantinople and Marseilles. Russian Licorice is now being shipped chiefly through Hamburg and London to the United States. Importations of this variety have been comparatively small. It occurs on the market both in the peeled and unpeeled condition, the peeled roots often being split lengthwise. Licorice is often offered for entry that is poorly dried, mouldy, insect infested or partially decayed; such roots should be rejected. According to Rusby (*Ph. Era,* 1909, p. 634), ground licorice has been imported which apparently consisted of the peelings of Russian licorice. Asiatic licorice, known as "*Chuntschir,*" is obtained from *G. uralensis*

Fisch. The plant is found in Siberia, Turkestan and Mongolia, and it is claimed that the root is of better quality and is but little inferior if any to the best Russian licorice. (See Alsberg and Viehoever, *J. A. Ph. A.*, 1919, viii, 467 and also *P. J.*, 1908, lxxxi, 164.)

The U. S. Department of Agriculture has had Spanish licorice under cultivation in South Carolina and the plant thrives in various localities in this country. It is said that the soil and climatic conditions in the Coachella Valley of California are ideal for the growing of the licorice plant.

A species of *Glycyrrhiza, G. lepidota* Pursh., grows abundantly from Missouri, westward into Nevada and northern California and northward to Washington. It is probably the same as the licorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Nuttall states that its root possesses in no inconsiderable degree the taste of licorice, and M. L. McCullough found it to contain 6.39 per cent. of crude glycyrrhizin, in contrast with 7.18 per cent. in the official species. (*A. J. P.*, 1890.) Schneider reports that *G. lepidota glutinosa* Pursh., a native of California, is much like *G. glabra* and can no doubt be substituted for the true licorice. (*Pacific Pharm.*, ii, p. 144.)

Description and Physical Properties.—"*Unground Spanish Licorice.*—Nearly cylindrical, the upper portion more or less knotty; usually in pieces from 14 to 20 cm. or more in length and from 5 to 20 mm. in thickness; externally yellowish-brown or dark brown, longitudinally wrinkled, the thinner rhizomes often having prominent alternate buds, the thicker rhizomes having distinct corky patches; fracture coarsely fibrous; internally yellow, radiate; odor distinctive; taste sweetish and slightly acrid.

"*Unground Russian Licorice.*—Nearly cylindrical, somewhat tapering, sometimes split longitudinally, from 15 to 30 cm. in length and from 1 to 5 cm. in diameter; when deprived of the outer corky layer, it is externally pale yellow; fracture coarsely fibrous; internally pale yellow; wood radially cleft; odor distinct; taste sweetish.

"*Structure.*—Rhizome with numerous layers of yellowish-brown cork cells, absent in the peeled drug; one or more rows of cells with a tendency to collenchymatous thickening; a middle bark of starch-bearing parenchyma and groups of bast-fibers surrounded with crystal-fibers; inner bark with radial arrangement of phloem and medullary rays, the phloem consisting of wedges of small groups of bast-fibers and parenchyma separated tangentially by sieve tissue, the cells of the latter with thick, highly refracting walls; medullary rays from 1 to 8 cells wide; wood bundles characterized by broad wedges consisting of large tracheæ with yellowish walls, small compact groups of wood-fibers and starch-bearing parenchyma; pith of large, more or less polygonal starch-bearing parenchyma or occasionally containing prisms of calcium oxalate. In roots the pith is absent.

"*Powdered Glycyrrhiza.*—Brownish-yellow (unpeeled Licorice) or pale yellow (peeled Licorice); starch grains numerous, mostly single and elliptical or oval, from 0.002 to 0.020 mm. in diameter; tracheæ mostly with bordered pores; wood- and bast-fibers numerous, very long, much attenuated at the ends and about 0.010 mm. in width; crystal-fibers with monoclinic prisms of calcium oxalate, the latter from 0.010 to 0.030 mm. in length; occasional fragments of reddish-brown cork cells which are practically absent in the powder prepared from peeled Licorice." *U. S.*

"When 5 grammes are macerated with 50 millilitres of *chloroform water* for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate evaporated in a flat-bottomed dish yield not less than 0.200 gramme of residue dried at 100° C. Ash not more than 6 per cent." *Br.*

A character said by Rothrock (*A. J. P.*, 1884) to be diagnostic of Glycyrrhiza is the occurrence of crystal fibers adjoining the wood and bast fibers. These are recognized in the official description of the powdered drug. In the Russian root the parenchymatous wood-cells are larger than in the Spanish. The powder is of a grayish-yellow color, when the root is pulverized without being deprived of its epidermis; of a pale sulphur-yellow, when the epidermis has been removed.

Constituents.—Besides various ordinary matter such as starch, lignin, etc., glycyrrhiza contains a brown acrid resin, a crystallizable substance originally called agedoïte but now known to be asparagin, and a characteristic principle known as *glycyrrhizin.* This is in reality the acid ammonium salt of *glycyrrhizic acid,* $C_{44}H_{62}NO_{18}.NH_4$. It is a glucoside which, according to Kobert (*Ph. Ztg.*, 1915, 182) belongs to the group of saponins and yields upon hydrolysis a hemolitic product; he also states that there are present in the root other saponins. Glycyrrhizic acid does not possess the characteristic sweetness of licorice, but its salts, especially the ammonium compounds, are sweet. Roussin in 1875 showed that licorice root which has lost a portion of its sweetness through fermentation, could be restored by treating with ammonium and suggested the name of *ammonium glycyrrhizate* as proper for the sweetening principle.

Glycyrrhizic acid is practically insoluble in cold water and the method of precipitating it from infusions of licorice root by means of sulphuric acid has been used for the purpose of assaying licorice (see under *Extractum Glycyrrhiza*). Habermann (*An. Ch. Ph.*, cxcvii) studied the properties of glycyrrhizic acid. He found that it was insoluble in ether, slightly soluble in absolute alcohol but more soluble in alcohol of lower percentage. It was only sparingly soluble in water but formed with it a transparent yellowish jelly. Houseman who has done considerable work on glycyrrhiza (*A. J. P.*, 1916, lxxxviii, 97) states that the biologically active saponins of licorice are in the inner bark. He also confirms the nitrogen content of glycyrrhizin which had been questioned.

Under the name of *Glycyrrhizinum Ammoniatum* (*Ammoniated Glycyrrhizin, Glyzina*), the U. S. IX recognized a crude form of this substance which it defined as "A sweet principle combined with ammonia obtained from glycyrrhiza." *U. S. IX.*

The process for making this preparation was given in the U. S. P. VIII as follows:

"Glycyrrhiza, in No. 20 powder, *five hundred grammes.* Water, Ammonia Water, Sulphuric Acid, each, *a sufficient quantity.* Mix *four hundred and seventy-five cc.* of Water with *twenty-five cc.* of Ammonia Water, and, having moistened the powder with the mixture, macerate for twenty-four hours. Then pack it moderately in a conical glass percolator, and gradually pour water upon it until *five hundred cc.* of percolate are obtained. Add Sulphuric Acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer, wash it with cold Water until the washings no longer have an acid reaction, redissolve it in Water with the aid of Ammonia Water, filter, if necessary, and again add Sulphuric Acid so long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of Ammonia Water previously diluted with an equal volume of Water, and spread the clear solution upon plates of glass, so that, when dry, the product may be obtained in scales." *U. S. P. VIII.*

The U. S. P. IX described it as follows: "Ammoniated Glycyrrhizin occurs in dark brown or brownish-red scales, without odor, and having a very sweet taste. It is freely soluble in water and soluble in alcohol. Its aqueous solution when heated with potassium hydroxide T.S. evolves ammonia. Supersaturate an aqueous solution of Ammoniated Glycyrrhizin with an acid; a precipitate is produced (consisting essentially of *glycyrrhizin*), which, when dissolved in hot water, forms a jelly on cooling. This substance, after being washed with diluted alcohol and dried, appears as an amorphous, yellow powder, having a strong, bitter-sweet taste, and an acid reaction. Incinerate 0.5 Gm. of Ammoniated Glycyrrhizin; not more than 0.5 per cent. of ash remains." *U. S. IX.*

According to Habermann glycyrrhizin is decomposed, by boiling with diluted sulphuric acid, into *glycyrrhetin* and *parasaccharic acid*, according to the reaction:

$$C_{44}H_{63}NO_{18} + 2H_2O = C_{32}H_{47}NO_4 + 2C_6H_{10}O_8.$$

By fusing glycyrrhizin with potassium hydroxide, Weselsky and Benedikt (*B. Chem. G.*, 1876) obtained *paraoxybenzoic acid.*

For methods of quantitatively determining glycyrrhizin, see *Ext. Glycyrrh.*

Uses.—Powdered licorice root is used for various pharmaceutical purposes as in the preparation of pills, either to give due consistence or to cover their surface and prevent them from cohering, and as a diluent of powdered extracts, etc. As a remedial agent it has been almost entirely replaced by the extract.

GOSSYPII CORTEX. N. F. (Br.)

COTTON ROOT BARK Gossyp. Cort.

"Cotton Root Bark is the recently gathered air-dried bark of the root of one or more of the cultivated varieties of *Gossypium herbaceum*, Linné, and of other species of *Gossypium* (Fam. *Malvaceæ*). Cotton Root Bark contains not more than 5 per cent. of wood or other foreign organic matter." *N. F.*

"Cotton Root Bark is the dried root-bark of Gossypium herbaceum, *Linn.*, and of other cultivated species of Gossypium." *Br.*

Gossypii Radicis Cortex, *Br.;* Ecorce de la Racine de Cottonnier, *Fr.;* Baumwoll-Wurzelrinde, *G.;* Corteza de la raiz d'algodon, *Sp.*

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species and which are merely varieties. By some taxonomists more than fifty species of *Gossypium* are recognized. There are only 5 or 6 species which yield useful products and the bulk of the cotton is the product of two species, *G. herbaceum* L., which furnishes the Upland or short staple cotton, and *G. Barbadense* L., the source of the Sea Island or long staple cotton. All of the species are of tropical origin. The Upland cotton has been cultivated in East India and Arabia since ancient times. The Sea Island cotton is indigenous to the West Indies and is the type observed by Columbus.

Gossypium herbaceum is a biennial or triennial plant, with a branching stem from two to six feet high and palmately-lobed hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers possess yellow petals, having a purple spot near the claw. The leaves of the involucre or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries. It requires a certain duration of warm weather to perfect its seeds, and, in the United States, does not ordinarily mature north of Virginia. It is cultivated widely in the Southern United States from Virginia to Texas.

Gossypium Barbadense (Sea Island cotton) differs from *G. herbaceum* in having smoother and more deeply lobed leaves, brighter yellow flowers, smaller, longer and more pointed bolls, and seed hairs with a finer and longer staple. It is cultivated chiefly in South Carolina, Georgia and Northern Florida.

The herbaceous part of the plant contains much mucilage, and has been used as a demulcent. The seeds yield by expression a fixed oil of the semi-drying kind, which is employed for making soap and for other purposes. (See *Oleum Gossypii.*) The portion, for which the plant is cultivated, is the filamentous substance surrounding the seeds. This, when separated, constitutes the cotton of commerce, and when purified, is official as *Gossypium Purificatum.* Cotton seeds have been employed in our Southern States in the treatment of intermittents, but are at present seldom, if ever used. (For details, see *U. S. D.,* 16th ed.)

Description and Physical Properties.—"*Unground Cotton Root Bark.*—In flexible bands or quilled pieces; attaining a length of 30 cm. and a thickness of about 1 mm.; outer surface orange-brown, sometimes smooth, but usually finely wrinkled and fissured longitudinally and roughened from the tendency of the corky layers to exfoliate the fibrous inner bark; inner surface light brown, longitudinally striate; fracture tough, fibrous, the inner bark readily separable into fibrous layers. Odor slight; taste very slightly acrid.

"*Structure.*—Cork composed of from 4 to 6 layers of tabular, yellowish brown cells with thin walls; a thin primary cortex consisting of starch-bearing parenchyma and occasional large secretion reservoirs with yellowish brown contents; inner bark with a nearly closed ring of V-shaped groups consisting of layers of strongly lignified bast fibers, sieve tissue, tannin-containing cells and traversed by medullary rays, the arrangement giving a deeply incised appearance to the outer edge of the bast ring when viewed in transverse section; medullary rays 1 to 6 cells in width, the cells usually containing starch grains; occasional cells containing rosette crystals of calcium oxalate.

"*Powdered Cotton Root Bark.*—Numerous bast fibers from 0.300 to 1.000 mm. in length and about 0.015 mm. in width, with strongly lignified walls, the latter about 0.005 mm. in thickness and with few pores, the ends of the fibers being acute and markedly attenuate; numerous fragments consisting of cortical parenchyma containing simple or compound starch grains, the latter up to 0.020 mm. in diameter, the tissue occasionally enclosing a secretory reservoir; fragments composed of medullary ray cells, the latter containing starch grains; rosette crystals of calcium oxalate from 0.009 to 0.025 cm. in diameter." *N. F.*

"In strips or quilled pieces; thin, tough and fibrous. Cork thin, pale brown, longitudinally striated; removed in places and then disclosing the orange-brown cortex. Inner surface whitish, silky and finely striated. Secondary bast readily separable into thin fibrous laminæ. No odor; taste slightly acrid and astringent." *Br.*

For an account of a microscopical and microchemical examination of cotton root bark by F. W. Morgan, see *A. J. P.,* 1898, p. 427. Farwell has made a histological study of the root and stem barks. (See *Merck's Rep.,* 1914, p. 133.) Stanford and Viehoever have made a detailed study of the glands of *Gossypium hirsutum* L. and their constituents. (See *J. Agric. Res.,* 1918, p. 419.) The drug of commerce frequently contains considerable woody material and many samples have been found to consist chiefly of segments of whole roots. It deteriorates with age and therefore only recently gathered bark should be used.

Power and Browning (*P. J.,* 1914, xciii, 420) found in an investigation of cotton root bark the following constituents: acetovanillone (in the steam distillate), a phenolic acid (probably 2:3 dihydroxybenzoic acid), salicylic acid, a new colorless phenolic substance, $C_9H_{10}O_8$, a new yellow phenolic substance, $C_{13}H_{18}O_5$, betaine, a fatty alcohol, $C_{20}H_{42}O$, a phytosterol, $C_{27}H_{46}O$, triacontane, ceryl alcohol, oleic and palmitic acids, and a sugar. Almost all of these constituents were separated from the resinous extractive which constituted between 10 and 11 per cent. of the air dried bark. No tannin was present and no alkaloids were detected.

Seeking the constituents of the Upland cotton plant, *Gossypium hirsutum,* that were attractive to the boll weevil, Viehoever, Chernoff and Johns studied the plant and found that the leaves and flowers (deprived of the petals) contained the glucoside, *quercimeritrin,* while the petals contained both quercimeritrin and *isoquercitrin.* These two glucosides are isomeric, having the formula $C_{21}H_{20}O_{12}$, and both hydrolyze to quercetin and dextrose. By distillation of 4000 pounds of fresh leaves of Upland cotton about 1 ounce of volatile oil, attractive to the boll weevil, was obtained. This oil on distillation was separated into 6 fractions passing over (*a*) below 200°, (*b*) 200–250°, (*c*) 250–270°, (*d*) 270–285°, (*e*) 285–300° and (*f*) 300–325°. Fraction "*d*" was the largest and consisted of a dark blue-green oil, which did not give any furol reaction nor deposit any crystals. (*J. Agr. Research,* 1918, xiii, 345.)

Uses.—The attention of the medical profession was called to cotton root bark by Bouchelle in 1840, who stated that it was a popular abortifacient among the negro slaves. Scott (*T. G.,* 1911) and Eckler (*Lilly Scientific Bull.,* 1920, p. 349) from studies on the lower animals, both reached the conclusion that it has a weak stimulating effect upon the uterus; while its action is similar in kind to that of ergot, it is scarcely to be compared because of its great inferiority in power.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Decoctum Gossypii Radicis Corticis, *Br.;* Extractum Gossypii Radicis Corticis Liquidum, *Br.;* Fluidextractum Gossypii Corticis, *N. F.*

GOSSYPIUM PURIFICATUM. U. S. (Br.)

PURIFIED COTTON Gossyp. Purif.
[Absorbent Cotton]

"The hairs of the seeds of cultivated varieties of *Gossypium herbaceum* Linné or other species of *Gossypium* (Fam. *Malvaceæ*) freed from adhering impurities and linters and deprived of fatty matter." *U. S.* "Cotton consists of the hairs of the seed of Gossypium herbaceum, *Linn.,* and of other cultivated species of Gossypium, freed from fatty matter." *Br.*

Gossypium, *Br.;* Cotton Wool; Lana (Lanugo, s. Pili) Gossypii; Coton Hydrophile, *Fr. Cod.;* Coton absorbant, Xylum præparatum, *Fr.;* Gossypium depuratum, *P. G.;* Gereinigte Baumwolle, Baumwolle, *G.;* Cotone assorbente, C. idrofilo, *It.;* Algodon hidrofilo, Algodon absorbente, *Sp.*

There is considerable difference in the capsules or so-called bolls, the seeds, as well as the lint of the several species of *Gossypium.* The bolls of Sea Island (*G. barbadense*) cotton are uniformly smaller, more sharply pointed, contain fewer and smaller seeds and longer lint than the Upland bolls. The Sea Island cotton has small black seeds from which the lint separates readily. The Upland cottons have large seeds which are greenish in color, and surrounded by a short dense hair beneath the longer and more valuable lint. The lint of the Sea Island cotton is from 3.5 to 6.5 cm. in length, while the Upland cotton seldom exceeds 3.5 cm. in length, usually being much shorter. There are numerous hybrids between these two types, *G. herbaceum* and *G. barbadense.* The long and extra long fiber produced in the United States are all obtained from varieties of *G. barbadense* and their hybrids, the shorter fibers being usually Upland cottons of the *G. herbaceum* type. The commercial grading of cotton by the New York Cotton Exchange is as follows: Samples the average fiber of which is under 25 mm. in length are called "short staple"; those between 25 to 30 mm. are called "medium" and from 30 to 40 mm. are called "long staple." What are known as "full grades" are designated by the words "fair," "middling fair," "good middling," "middling," "low middling," "good ordinary" and "ordinary."

The inadequacy of the former U. S. P. requirements for absorbent quality having been pointed out in several articles by Dr. F. B. Kilmer, the suggestions made by him for improvement of the standards have all been adopted in later U. S. P. texts.

In the process of purifying cotton a soap is formed through the union of the fatty matter with the alkali, and this is subsequently dissolved out by repeated washings. F. L. Slocum published in 1881 a process for preparing it as follows: Take of the best quality of carded cotton batting any desired quantity, and boil it with a 5 per cent. solution of potassium or sodium hydroxide for one-half hour, or until the cotton is entirely saturated with the solution, and the alkali has saponified all oily matter. Then wash thoroughly, to remove all soap, and nearly all alkali, press out the excess of water, and immerse in a 5 per cent. solution of chlorinated lime for 15 or 20 minutes; again wash, first with a little water, then dip in water acidulated with hydrochloric acid, and thoroughly wash with water; press out the excess of water, and again boil for 15 or 20 minutes in a 5 per cent. solution of potassium or sodium hydroxide; now wash well, dipping in the acidulated water and rinsing thoroughly with pure water. Afterwards press out and dry quickly.

The amount of loss by this process is practically 10 per cent. A sample of 360 gr. lost, on boiling with alkali and bleaching, 15 gr., or 4.17 per cent., and 270 gr. of this bleached sample lost, on again boiling with an alkali, 14 gr., or 518 per cent., a total loss of 9.35 per cent. (*A. J. P.,* 1881, 53; see also *Ph. Era,* 1890, p. 22).

Description and Physical Properties.—"White, soft, fine filaments, appearing under the microscope as hollow, flattened and twisted bands, spirally striate and slightly thickened at the edges. It is odorless and almost tasteless. Purified Cotton is insoluble in ordinary solvents, but is soluble in ammoniated cupric oxide T.S.

"Purified Cotton, previously compressed in the hand, when thrown on the surface of water at about 25° C., readily absorbs it and sinks. Ash: not more than 0.2 per cent. Thoroughly saturate about 10 Gm. of Purified Cotton with 100 cc. of distilled water, then with the aid of a glass rod press out two 25 cc. portions of the water into white porcelain dishes. Add to one portion 3 drops of phenolphthalein T.S. and to the other portion 1 drop of methyl orange T.S.: no pink color develops in either portion (*alkali or acid*). Pack 10 Gm. of Purified Cotton in a narrow percolator, extract with ether, until the percolate measures 200 cc., and evaporate to dryness: the residue does not exceed 0.6 per cent. (*fatty matter*). Pack 10 Gm. of Purified Cotton in a narrow percolator, and extract with alcohol until the percolate measures 50 cc.: when observed downward through a column 20 cm. in depth, the percolate may show a yellowish color, but no blue or green tint (*dyes*). Place 10 Gm. of Purified Cotton in 200 cc. of boiling distilled water in a porcelain dish; keep the water at about 100° C. for five minutes, holding the cotton under the surface with the aid of a glass rod. Then press out with the assistance of the rod, and decant 100 cc. of the water, filtering it if not clear. Now add 50 cc. of cold distilled water to the Purified Cotton, thoroughly working it through the Cotton with the glass rod, for ten minutes, and again decant 50 cc. of the water. Twice again wash the Cotton with 50 cc. portions of cold distilled water, in the manner described, and evaporate to dryness the combined washings so obtained in a porcelain or platinum dish on a water bath. The residue, dried to constant weight at 100° C., does not exceed 0.025 Gm. (*water-soluble substances*)." *U. S.*

"In long, white, soft filaments, each consisting of an elongated cell, appearing, when seen under the microscope, as a flattened, twisted band with slightly thickened rounded edges. Inodorous and tasteless. Soluble in *ammoniacal solution of copper oxide*. Readily wetted by *water*, and not imparting to it either an alkaline or an acid reaction. Ash not more than 0.5 per cent." *Br.*

It is without odor or taste, soluble in strong alkaline solutions, and decomposed by the concentrated mineral acids. In chemical character it is related to but not identical with lignin, the latter being called *lignocellulose*, whereas cotton is composed of *cellulose*, $(C_6H_{10}O_5)n$. By nitric acid it is converted into gun-cotton (see *Pyroxylinum*). *Mercerized cotton* is made by treating woven cotton fabrics with concentrated sodium hydroxide solution which so modifies the fiber that a sheen like silk is produced. This must not be confused, however, with *artificial silk* (*rayon*) which is made by several processes using cotton or cellulose is taken as the starting point. In one of these the cellulose is converted into a nitroderivative which, after dissolving in suitable solvents to make a thick solution, is drawn out into threads which are subsequently denitrated and made less inflammable by immersing them in alkaline sulphide solution. In another method the cellulose is treated with alkali and carbon disulphide which forms cellulose thiocarbonate or xanthate which when treated with water yields "*viscose*," a thick tenacious substance capable of being drawn into glossy threads. In another process the solvent powers of an ammoniated copper is utilized. *Acetylcellulose* or *cellulose acetate* is made by the action of acetic anhydride upon cotton. It is used for making non-inflammable moving picture films and for making the transparent thin sheets used for wrapping confectionery and for other purposes where an air-tight package is desirable.

A method of distinguishing between these four types of rayon is afforded by the use of a reagent called *ruthenium red*. This is an aqueous soultion of $Ru_2(OH)_2Cl_4(NH_3)_7.3H_2O$ in the proportion of 1 in 1000. If an unknown sample of rayon is treated with the reagent for a twelve hour period the following distinguishing results are observed: Viscose rayon shows a distinct pink color, which becomes more pronounced upon standing. Denitrate nitro-rayon is colored red, which becomes violet upon standing. Copper ammonium rayon is not colored even after twelve hours. Acetate rayon is colored irregularly but this variety is distinguished from the others by its ready solubility in glacial acetic acid, the other varieties being insoluble in this reagent.

The first U. S. P. IX test proves the absence of fatty matter, for if even a small quantity be present the cotton will float in water. Repeated experiments have proved that cotton will take fire spontaneously if impregnated with linseed oil, or some of the other fixed oils, and allowed to stand; the heat produced by the oxidation of the oil suffices to ignite the matted fibers of the cotton. For medicinal use it should be carded into thin sheets. Air passed through cotton becomes sterile on account of the microscopic organisms being strained out of it; and this fact has been utilized in preserving infusions by placing them in bottles containing corks armed with tubes loosely filled with cotton, and drawing the infusion from a stopcock near the bottom.

Wood Wool.—Under this name Bruns has introduced finely grained, purified wood fiber, such as is used in making paper. It may be medicated like cotton.

Uses.—The use of cotton as a filtering medium and in the preparation of medicated waters has already been alluded to. It is much used in surgery as a dressing for *burns* and *wounds*, in order to prevent the access of pathogenic germs and to absorb discharges. Cotton batting is often employed to maintain a uniform temperature in parts affected with *acute rheumatic inflammation*. Absorbent cotton has been medicated in various ways and come largely into use. (For *Iodized Cotton*, see *Iodum.*) *Picric Cotton* is prepared by dissolving 0.25 Gm. of picric acid in 25 Gm. of ether, or of 94 per cent. alcohol, and immersing in the solution 10 Gm. of clean cotton, and drying. *Salicylic Cotton* (5 per cent.) may be prepared by Brun's process, by saturating one kilogramme of cotton with 4 liters of a solution of 50 Gm. of salicylic acid, and 20 Gm. of castor oil in 3.930 liters of alcohol. England communicates in *A. J. P.*, 1887, p. 173, practical formulas for preparing the following medicated cottons and gauzes: *Borated Cotton, Benzoated Cotton, Salicylated Cotton, Naphthalinated Cotton, Iodoformized Cotton, Carbolized Cotton, Sublimated Cotton, Carbolized Gauze, Sublimated Gauze, Absorbent Canton Flannel.* For methods of assay of medicated cottons, gauzes, etc., see *Proc. A. Ph. A.*, 1897, 457. See also formulas for the extemporaneous preparation of medicated gauzes, by George M. Beringer, Jr., *A. J. P.*, 1911, p. 178.

Off. Prep.—Pyroxylinum, *Br.;* Gossypium Stypticum, *N. F.*

GRANATUM. U. S.

POMEGRANATE Granat. [Pomegranate Bark]

"Pomegranate is the dried bark of the stem or root of *Punica Granatum* Linné (Fam. *Granataceæ*). Pomegranate contains not more than 2 per cent. of wood or other foreign organic matter." *U. S.*

Granati Cortex, *Br.*, 1898; Pomegranate Bark; Cortex Mali Punici, Ecorce de Grenadier, *Fr. Cod.;* Ecorce deBalaustier, Ecorce de Granade, *Fr.;* Cortex Granati, *P. G.;* Granatrinde, Granatwurzelrinde, *G.;* Melogranato, Malicorio, Scorza del Melogranati, *It.;* Granado (Corteza de), *Sp.*

The *pomegranate* is a small tree, attaining in favorable situations the height of twenty feet, with a very unequal trunk, and numerous branches which sometimes bear thorns. The leaves are opposite, petiolate, entire, oblong or lance-shaped, pointed at each end, smooth, shining, and of a bright-green color. The flowers are large, of a rich scarlet color, and stand at the end of the young branches. The petals are wrinkled and inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular pome-like berry, about the size of an orange, crowned with the persistent calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many loculi, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot-houses for the beauty of its flowers, which become double and acquire increased splendor of coloring by cultivation. Doubts have been entertained as to its original country. The name of *Punicum Malum*, applied by the ancients to its fruit, implies that it was abundant at an early age in the vicinity of Carthage. The fruit, for which the plant is cultivated, varies much in size and flavor. It is said to attain greater perfection in the West Indies than in its native country. The edible pulp is red, succulent, pleasantly acid, and sweetish. See a paper by J. U. Lloyd in *West. Drug.*, 1897, 202.

The pomegranate may be grown in the United States as far north as Maryland. It is cultivated to some extent in California, and the Gulf States as a garden and hedge plant. The seeds are utilized in the south in making cooling drinks. There are several varieties of the pomegranate, the typical having an acid pulp, and others having a sweet and sub-acid character. There is an East Indian variety which is seedless and is highly prized in India. There are several double-flowered varieties which do not bear fruit and are largely cultivated in the south and in green-houses for ornamental purposes.

The *rind of the fruit* is seen in commerce in the form of irregular fragments, hard, dry, brittle, of a yellowish or reddish-brown color externally, paler within, without odor, and of an astringent, slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds, has been employed for tanning leather.

The flowers, sometimes called *balaustines,* are inodorous, have a bitterish, astringent taste, and impart a violet-red color to the saliva. They contain tannic and gallic acids, and were used by the ancients in dyeing.

Description and Physical Properties.—"*Unground Pomegranate.*—Stem bark in pieces from 2 to 8 cm. in length; bark from 0.5 to 3.5 mm. in thickness; outer surface yellowish to grayish-brown, with patches of grayish lichens, broadly elliptical lenticels and yellow-brown furrows or abraded patches of cork; longitudinally wrinkled; inner surface light yellow or yellowish-brown, finely striate; fracture short; phelloderm dark green; inner bark yellowish-green.

"Root bark in transversely curved pieces; externally brownish-yellow with conchoidal depressions and dark brown irregular patches in the cork; internally dark yellow, the medullary rays extending nearly to the outer surface.

"In either root or stem bark, odor slight, taste astringent, somewhat bitter and nauseous.

"*Structure.*—Cork thin, of alternating rows of thin-walled suberized cells and lignified cells with greatly thickened inner walls; cortex of parenchyma with a few large stone cells isolated or in small groups; medullary rays mostly 1-cell wide; rosette aggregates of calcium oxalate very numerous in the parenchyma.

"*Powdered Pomegranate.*—Yellowish-brown to dark brown; calcium oxalate crystals in rosette aggregates or monoclinic prisms from 0.006 to 0.018 mm. in diameter; starch grains numerous, spherical, ellipsoidal, biconvex or irregular and single or compound, from 0.002 to 0.010 mm. in diameter; fragments of whitish cork with prominent, thickened, lignified walls; stone cells from 0.050 to 0.300 mm. in length, the walls being very thick and strongly lamellated; occasional long wood fibers from 0.015 to 0.020 mm. in thickness and associated with tracheæ possessing simple and bordered pores.

"Mix 1 Gm. of powdered Pomegranate with 100 cc. of distilled water, macerate it with occasional agitation for about an hour, and filter; a light yellow filtrate is obtained. Upon the addition of a drop of ferric chloride T.S. to 10 cc. of this filtrate, a bluish-black precipitate is produced. Upon the addition of from 40 to 50 cc. of calcium hydroxide T.S., to another 10 cc. portion of the filtrate, an orange-brown, flocculent precipitate is produced.

"Preserve in tightly closed containers." *U. S.*

The bark of the stem of the pomegranate differs from the root bark by the presence of a broader cortex whose outer cells contain chloroplastids and by possessing shorter medullary rays. The commercial supply of pomegranate bark is obtained chiefly through Marseilles, France.

The inner surface of the bark, steeped in water and then rubbed on paper, produces a yellow stain, which by the contact of ferrous sulphate is rendered blue, and by that of nitric acid acquires a slight rose tint, which soon vanishes. These properties serve to distinguish this bark from those of the box root and barberry. When used, it should be separated from the ligneous portion of the root, as the latter is inert.

Granatum is sometimes substituted by the barks of other plants. Among these are *Berberis vulgaris,* which is bitter and not astringent; *Buxus sempervirens,* which is also bitter and free from tannin; and *Strychnos Nux Vomica* or false Angostura bark which has a dark inner surface and a very bitter taste. None of these barks have the characteristic checkered appearance of the transverse surface of genuine Granatum.

Constituents.—Rembold (*Ann. Ch. Phys.,* cxliii, p. 285) found in the bark about 22 per cent. of a tannin which he thought was peculiar and called *punico-tannic acid* but which Trimble (*A. J. P.,* 1897, p. 636) has shown to be gallo-tannic acid.

Pomegranate bark also yields a considerable quantity of mannite, which was formerly described under the names of *punicin* or *granatin.* The medicinal value of the root, however, is due to the alkaloids discovered by Tanret in 1878 to 1880 (*C. R. A. S.,* lxxxvi, p. 1270 and lxxxviii, p. 716); the first of these he named *pelletierine,* $C_8H_{15}ON$. It is a dextrogyrate liquid boiling at 195° C., easily soluble in water, alcohol, and ether, and especially so in chloroform. It has strong basic properties and precipitates many metallic salts: 1000 parts of dry bark yielded 4 parts of it. In addition he has found three volatile bases in the bark, a liquid left-rotating one, a liquid optically inactive one, and a crystallizable inactive one, to which the names of *methylpelletierine,* $C_9H_{17}ON$, and *pseudopelletierine* (*granatonine*), $C_9H_{15}ON$, and *isopelletierine,* have been given. Carl J. Bender (*Ph. Centralh.,* 1885, p. 6) objects to the name pelletierine, and substitutes *punicine.*

Hess and Eichel (*B. Chem. G.,* 1917, l; 1919, lii, 1005) state that the alkaloid reported by Picinni as *methyl-isopelletierine* is identical with Tanret's methyl-pelletierine. They have also added two more to this list: *iso-pelletierine,* $C_8H_{15}ON$ and *alpha-N-methylpiperidyl-2-propanone,* $C_9H_{17}ON$. Flückiger stated that methylpelletierine predominates in the bark of the root and pelletierine in the bark of the overground portions of the plant.

The alkaloids are prepared by extracting a finely ground mixture of pomegranate and slacked lime with water and shaking out from this with chloroform; the alkaloids are then extracted from the chloroform by means of a weak aqueous solution of hydrochloric acid. The separation of the mixed chlorides is accomplished by fractional distillation.

The bark of the stem usually contains slightly less alkaloid than the bark of the root. The amount in the stem bark has been determined by various investigators to range from 0.35 to 0.6 per cent. and in the root, from 0.6 to 1.0 per cent. Stoeder (*Nederl. Tijd. Pharm.,* 1890) found that of the root bark of three varieties of the wild pomegranate recognized and used by the natives of Java, the red-flowered 'merah,' yielded 2.43 per cent.; the white-flowered, 'poetih,' yielded 3.75 per cent.; the black-flowered, 'hitam,' yielded 1.71 per cent. Wm. F. Junkunz believes that the alkaloid exists in the bark as a tannate. (*A. J. P.,* 1884.) The old idea that the bark loses activity when kept seems to be negatived by the analysis of De Vrij. (*P. J.,* xxi.)

For Leger's method of determining total alkaloids, see *P. J.,* 1904, 581. Assay processes for granatum are given in most of the foreign pharmacopœias and these were critically reviewed by Dichgans (*Ph. Ztg.,* 1914, 852), who finds the one in the Swiss Pharmacopœia to be the best.

Uses.—The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna, but was unknown in modern practice until brought into notice by F. Buchanan, who learned its powers in India. The Mahometan physicians of Hindostan consider it a specific against *tænia.* One of these practitioners, having relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. The French writers prefer the product of the wild pomegranate, growing on the borders of the Mediterranean, to that of the plant cultivated in gardens for ornamental purposes. The bark may be administered in powder or decoction, but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling to a pint. Of this a wineglassful may be given every half hour, hour, or two hours, until the whole is taken. It often nauseates and vomits, and usually purges. Portions of the worm often come away soon after the last dose. It is recommended to give a dose of castor oil and to diet the patient strictly on the day preceding the administration of the remedy, and, if it should not operate on the bowels, to follow it by castor oil, or an enema. If not successful on the first trial, it should be repeated daily for three or four days, until the worm is discharged.

Although the value of pomegranate in the treatment of *tape-worm* was known to the ancients and commented on by Dioscorides, the drug fell into disuse in Europe for several centuries until revived by Buchanan in 1805. The efficacy of its alkaloids as tænicides has been abundantly confirmed, and it appears to be established that the tannate of the alkaloids is the most effective and the least dangerous form of the remedy,—probably because its insolubility prevents its rapid absorption and enables it to come in prolonged contact with the worm. (See *Pelletierinæ Tannas*).

The rind of the pomegranate fruit (*Granati Fructi Cortex*) was formerly recognized by the U. S. Pharmacopœia (1870). It is astringent, and in the form of decoction is sometimes employed in *diarrhea* and *colliquative sweats*, and, more frequently, as an injection in *leucorrhea*, and as a gargle in *sore throat* in the earlier stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in *intermittent fever*. The flowers have the same medicinal properties and are used for the same purposes. The dose of pomegranate rind and flowers in powder is from twenty to thirty grains (1.3–2.0 Gm.). *Decoctum Granati Corticis* was formerly official in the British Pharm. (1898). The decoction may be prepared in the proportion of four ounces of the bark to twenty fluidounces of water, and given in the dose of half a fluidounce (15 cc.). The remedy should always be given after a twelve hours' fast, and be followed in two hours by a brisk cathartic. The seeds are demulcent.

Dose, of granatum, twenty to thirty grains (1.3–2.0 Gm.).

Off. Prep.—Fluidextractum Granati, *U. S.*

GRINDELIA. N. F., Br.

GRINDELIA Grindel.

"Grindelia consists of the dried leaves and flowering tops of *Grindelia camporum* Greene, or *Grindelia cuneifolia* Nuttal, or *Grindelia squarrosa* (Pursh) Dunal (Fam. *Compositæ*). Grindelia contains not more than 10 per cent. of stems of over 2 mm. in diameter, or more than 2 per cent. of other foreign organic matter." *N. F.*

"Grindelia consists of the dried leaves and flowering tops of Grindelia camporum, *Greene*." *Br.*

Gum Plant, Tar Weed; Herba Grindeliæ; Grindelie, G.

The genus *Grindelia* includes some twenty-five species, six or eight of which are found in South America and the remainder occurring in the United States west of the Mississippi. They are coarse perennial or biennial herbs, being occasionally shrub-like. Most, if not all, of the species produce a sticky resinous exudation on the stem and leaves and especially on the flower-heads, whence they are called "gum plants." The leaves are alternate, sessile or clasping and spinulose-dentate. The flowers occur in heads which are either solitary on the ends of branches, or in cymes or panicles. Both the outer ray florets and the central tubular florets are yellow in color. The ray flowers are pistillate and the involucre is bell-shaped or hemispherical, the bracts being imbricated, in several series, being usually subulate-tipped. The drug of the market appears to be derived in large part from *G. camporum* Greene, which is the common *"gum plant"* of California. It occurs abundantly in the inner coast ranges, where it has been collected in quantity in Lake and Napa Counties. It is also common in the foot hills of the Sierra Nevada and is almost the only plant found on the plains in certain regions of the Sacramento Valley. The leaves are oblong or spatulate, sessile or clasping, coarsely serrate and of a pale-green color. The flower-heads are yellow and the involucre consists of several rows of lanceolate acuminate recurved bracts. The achenes are distinctive in this species and are usually biauriculate or more rarely unidentate at the summit.

G. cuneifolia closely resembles *G. camporum.* The leaves are cuneate-oblong or linear-oblong and either sessile or amplexicaul. It is a marsh plant and is not as glutinous as *G. camporum.* The leaves of this species, in addition to their being cuneiform in shape, are darker green and not so thick as in *G. camporum.* The achenes are compressed and closely resemble those of *G. camporum.*

G. squarrosa is a common plant on the prairies and dry banks of the West. It is occasionally found in the East where it is hardy. It has been reported as occurring from the Saskatchewan to Minnesota, Texas, California and Mexico. It is a glabrous, erect, branching herb having linear-oblong or spatulate leaves, which are more or less clasping at the base and sharply spinulose-dentate. It is especially characterized by the bracts of the involucre being linear-lanceolate, subulate tipped and spreading or squarrose at the summit, giving the species its name. The achenes are truncate, those of the outer flowers being usually thicker. The pappus consists of two or three awns.

It was formerly supposed that the drug of commerce was derived from *G. robusta.* The studies of Perrédès (*Proc. A. Ph. A.*, 1906, 370) showed this not to be the case. *G. robusta* is apparently not a very common plant and is distinguished by having cordate-oblong, amplexicaul, coarsely serrate leaves. The involucre is squarrose and leafy at the base. The pappus consists of two awns. At one time both *G. cuneifolia* and *G. camporum* were considered merely as varieties of *G. robusta.* According to Jepson (*Flora of Western Middle California*), there is more divergence between the varieties of *G. robusta* than between the species *G. camporum* and *G. rubricaulis.*

According to Joseph Beauvais (*A. J. P.*, Feb., 1889), the resin of the leaf of *G. robusta* is contained in epidermal glands, and also in rather large resin-ducts situated in an interior collenchymatous layer.

The leafy tops of the Grindelia species are gathered in July and dried in the sun. Most of the commercial supplies come from California and other southwestern states.

Description and Physical Properties.—"*Unground Grindelia.*—Stems and branches cylindrical, light yellow or rose-colored, with alternate leaf scars, occasionally with basal portions of leaves, sometimes irregularly flexous and coated with resin, and terminating in resinous flower heads; leaves usually separate from the stem and broken, oblong to oblong-spatulate, from 1 to 7 cm. in length, mostly sessile or amplexicaul and sharply serrate or evenly spinosely toothed, pale yellow to yellowish green, very resinous, somewhat coriaceous and brittle; bracts of flowering branches almost entire and usually more or less spreading; flower-heads from 5 to 20 mm. in diameter, urn-shaped and conical when unexpanded but flattened or depressed when partly open and usually very resinous; involucre bracts numerous, imbricated, with recurved tips; ray florets yellow or brownish, ligulate and pistillate; disk florets yellow, tubular and perfect; pappus of two or three mostly unequal linear awns about the length of the disk florets; disk achenes ovoid or oblong; compressed, four-angled or triquetrous, and either biauriculate or broadly unidentate or with a broad truncate, corky, thickened summit. Odor balsamic; taste aromatic and bitter, resinous.

"*Powdered Grindelia.*—Yellowish brown; consisting of numerous fibrous fragments, bearing tracheæ with annual and spiral thickenings or marked with simple or bordered pores, associated with numerous, narrow, strongly lignified wood fibers; pith cells more or less tabular and containing a layer of protoplasm in which are embedded numerous spheroidal granules; fragments of leaf epidermis showing more or less polygonal areas containing cloroplastids and colorless, basal cells of the glandular hairs; the latter with compound heads up to 0.100 mm. in diameter each cell of which contains a rosette crystal from 0.005 to 0.008 mm. in diameter; pollen grains spherical, about 0.035 mm. in diameter, spinose, and in section showing three pores." *N. F.*

"Stems slender, yellow, smooth. Leaves three to five centimetres long, oblong or spatulate, sessile or amplexicaul, pale green, rigid, brittle, smooth, glabrous; surface minutely dotted; margin coarsely serrate. Flower-heads yellow, hard, resinous, with several rows of lanceolate-acuminate, recurved bracts. Fruits bi-auriculate or unidentate at the summit, with a pappus consisting of two thick, stiff bristles. All parts more or less resinous. Slightly aromatic odor; taste aromatic and bitter." *Br.*

As it occurs in commerce, grindelia is in the form of the whole dried herb; the stems are about eighteen inches in length, light brownish, very frequently stripped of their leaves, but with some of the floral heads adherent. The brittle leaves are much broken, and, with separate floral heads, are mixed with the stem. The taste is warm, peculiar, and very persistent. Tunmann (*Ph. Zentralh.*, 1908, p. 457) has made an excellent pharmacognostical study of *G. robusta.* Wohn (*Merck's Rep.*, 1910, p. 310) presents the results of a morphological study of *G. squarrosa.* Farwell (*D. C.*, 1907, p. 460) reports having received one of the California "tar weeds," *Hemizouella minima* Gray, for grindelia. The plant is very diminutive in size, but the inflorescence is very glutinous. Perrédès (*P. J.*, 1909, xxix, pp. 596 and 604) gives the results of some experiments in the cultivation of *G. camporum.*

The activity of the drug probably resides in the resinous exudation. Clark and Fischer (*A. J. P.*, 1888) reported the presence of an alkaloid, *grindeline,* and Schneegans (*A. J. P.*, 1892) the presence of a glucosidal saponin. Power and Tutin (*Proc. A. Ph. A.*, 1905 and 1907) were unable to confirm these results and attributed the value of the drug to the amorphous resins which compose over 21 per cent. of the drug. The greater portion of this resinous matter was a complex mixture of liquid acids which were chiefly unsaturated cyclic compounds and were optically active. They found also traces of a bright yellow volatile oil possessing to a high degree the characteristic odor of the drug. *Grindelia robusta* is said to contain 0.28 per cent. of a dark-brown essential oil, having a specific gravity of 0.9582 at 15° C., and the optical rotation in alcoholic solution of –8° 08′. It is soluble in ether, amyl alcohol, and chloroform. (*Ph. Ztg.*, 48, 574.)

Uses.—Grindelia is possessed of only feeble physiologic powers, but according to Buffington, when given to the lower animals in very large doses produces narcosis, with dilated pupils, slowing of the action of the heart from stimulation of the inhibitory nerves, and elevation of the blood pressure from stimulation of the vasomotor center. Dobroklowsky has found that it had a primary stimulating and later depressant effect on the isolated frog's heart. He further states that it acts chiefly upon the motor nerves and muscles, but Buffington asserts that it paralyzes first the sensory nerve-trunks, then the sensory side of the spinal cord, and afterwards involves the motor nerve-trunk and cord. Grindelia is used in the treatment of *bronchial catarrhs,* especially when there is a tendency to *asthma.* Its action is probably simply that of a stimulating expectorant, but some believe it exerts also an antispasmodic influence. It is frequently used in conjunction with stramonium leaves in the preparation of "Asthma powders" or cigarettes. It has been employed with asserted success in *whooping cough.* Its active principles appear to be excreted from the kidneys; hence, after large doses, there are sometimes evidences of renal irritation, and in chronic *catarrh of the bladder* good has been effected by its stimulant influence upon the mucous membrane of the viscus. As a local application, grindelia has been employed with asserted advantage in *burns, vaginitis, genito-urinary catarrh,* etc., applied either in the form of a poultice or in solution. It has considerable use also as a local application in the treatment of *rhus poisoning.* The fluidextract, diluted with water, is employed.

Dose, thirty to forty grains (2.0–2.6 Gm.).

Off. Prep.—Fluidextractum Grindeliæ, *N. F.* (*Br.*).

GUAIACI LIGNUM. Br.

GUAIACUM WOOD

"Guaiacum Wood is the heart-wood of Guaiacum officinale, *Linn.*, or of Guaiacum sanctum, *Linn.*" *Br.*

Lignum Sanctum (vel Benedictum); Lignum Vitæ; Gaïac, Bois de Gayac, *Fr.;* Lignum Guajaci, *P. G.;* Guajakholz, Franzosenholz, Pockholz, *G.;* Guajaco, Legno guajaco, *It.;* Guayaco (Leño de), *Sp.*

This drug is not official in the U. S., but the resin is recognized by the N. F.

Guaiacum officinale (Fam. *Zygophyllaceæ*) is a middle-sized or low evergreen tree indigenous to the West Indies and northern part of South America. The branches are knotted, and covered with an ash-colored striated bark. That of the stem is of a dark-gray color, variegated with greenish or purplish spots. The leaves are opposite, leathery, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue color, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

G. sanctum L. is distinguished from *G. officinale* by its five-celled fruit and its oblong or obliquely obovate or sometimes rhomboid-ovate leaflets, six to eight to each leaf. It grows in Cuba, Haiti, the Bahama Islands and Florida. Its wood is smaller than that of *G. officinale,* and is said by Fée to be paler and less dense.

The commercial supplies are shipped from Cuba, Haiti and the Dominican Republic to the United States and Europe.

As imported, guaiac wood is in the shape of logs or billets, covered with thick gray bark, which presents on its inner surface, and upon its edges, when broken, numerous shining crystalline particles. These were supposed by Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant; but Otto Berg has determined that they are crystals of calcium sulphate. The billets are used by turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. The waste heartwood, consisting of raspings or shavings from turners, is usually alone employed in pharmacy and medicine. It is commonly called *lignum vitæ,* a name which obviously originated from its durable properties.

Properties.—Guaiacum wood is hard and heavy. The color of the sap-wood is yellow, that of the older and central layers greenish-brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division its color is rendered green by exposure to the air, and bluish-green by the action of nitric acid fumes, and the latter change may be considered as a test of its genuineness. (Duncan.) An easier test is a solution of corrosive sublimate, which, added to the shavings and slightly heated, causes a bluish-green color in the genuine wood. Guaiacum wood is almost without odor unless rubbed or heated, when it becomes odorous. When burned, it emits an agreeable odor. It is bitterish and slightly pungent, but requires to be chewed for some time before the taste is developed.

"Dark greenish-brown, dense, hard; heavier than water. In transverse section, abundant sclerenchymatous fibres, scattered, isolated vessels, and medullary rays one cell wide. Odor, on warming, somewhat aromatic; taste slightly acrid. An alcoholic tincture prepared from the Wood assumes a blue color in the addition of diluted *T. Sol. of ferric chloride.*" *Br.*

The N. F. IV described it as follows: "Usually in the form of shavings, chips or raspings of a greenish-brown color, heavier than water, entirely free from adhering bark and containing only a few chips or shavings of a whitish color (*sap wood*). Almost odorless except when heated; taste bitter and acrid when chewed for some time. The powder, when examined under the microscope, exhibits numerous fragments of more or less lignified, thick-walled wood fibers, up to 0.028 mm. in width, some with simple, oblique pores; tracheæ from 0.09 to 0.16 mm. in width, some filled with resin; numerous small masses of resin; wood parenchyma and medullary ray cells up to 0.02 mm. in width, with lignified, porous walls and usually containing resin; occasionally tangential views of the medullary rays show an elliptical group of from three to six cells; the resin masses and resinous tissue become bluish-green on the addition of iodine T.S. Place powdered Guaiac Wood in a solution of sodium chloride (1 in 3); the blackish-brown part only will sink and this does not exceed in amount the portion which floats. Shake 10 cc. of alcohol with 0.5 Gm. of ground Guaiac Wood for a few seconds and filter the mixture; the filtrate yields a deep blue color with one drop of a solution of ferric chloride (1 in 10). Guaiac Wood yields to alcohol not less than 15 per cent. of extractive. Guaiac Wood yields not more than 3 per cent. of ash." *N. F. IV.*

Guaiac wood contains, according to Trommsdorf, 26 per cent. of resin, and 0.8 of bitter pungent extractive, upon both of which, probably, though chiefly on the former, its medicinal virtues depend. (See *Guaiacum.*) Paetzold (*Schim. Rep.*, 1902, 43) states that the bark of the guaiac tree yields 1 per cent. of a volatile oil, having an exquisite odor. The wood yields its virtues but slightly to water. One pound of the wood afforded to Geiger two ounces of extract.

Uses.—Guaiacum wood possesses no therapeutic powers which are not contained in its resin and the latter is always to be preferred.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Decoctum Sarsaparillæ Compositum, *N. F.*

GUAIACUM. N. F. (Br.)

GUAIAC Guaiac. [Guaiac Resin]

"Guaiac is the resin of the wood of *Guajacum officinale* Linné or of *Guajacum sanctum* Linné (Fam. *Zygophyllaceæ*). Guaiac yields not more than 15 per cent. of residue insoluble in alcohol." *N. F.*

"Guaiacum Resin is the resin obtained from the stem of Guaiacum officinale, *Linn.*, or of Guaiacum sanctum, *Linn.*" *Br.*

Guaiaci Resina, *Br.;* Guaiac; Guaiacum Resin; Résine de Gaïac, *Fr. Cod.;* Resina Guajaci, *P. G.;* Guajak, Guajakharz, *G.;* Resina de guajaco, *It.;* Resina de guayaco, *Sp.*

For a description of *Guaiacum officinale,* see *Guaiaci Lignum.*

Guaiac resin was introduced into the London Pharmacopœia in 1677. It exists in the tree as a physiological product filling up the tissues of the wood. It is obtained in several different modes. The most simple is by spontaneous exudation, or by incisions made into the trunk. Another method is by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. But the plan probably most frequently pursued is to boil the wood, in the state of chips or sawdust, in a solution of common salt, and skim off the substance which arises to the surface. Guaiac resin is chiefly produced in the eastern portion of the Island of Haiti, being exported from Azua and Gonaïves in bags within cases. Formerly, the quality of the drug was often bad, being loaded with bark and wood. At present much of it is so clean that it appears to be strained. It is usually in large irregular pieces of various sizes, in which small fragments of bark, sand, and other impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes it is found in small roundish homogeneous portions, separate or agglutinated; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac obtained from the billets in the manner above described is of uniform consistence.

Description and Physical Properties.—"In irregular fragments or in large, nearly homogeneous masses, occasionally in more or less rounded or ovoid tears, enclosing fragments of vegetable tissues; externally brown, becoming greenish gray-brown on exposure, the fractured surface having a glassy luster, the thin pieces being translucent and varying in color from reddish to yellowish brown. The powder is grayish, becoming green on exposure to the air. Odor balsamic; taste slightly acrid.

"Guaiac melts between 85° and 90° C. It is readily soluble in alcohol, ether, chloroform, creosote, and in solutions of the alkalies or in chloral hydrate T.S. It is sparingly soluble in carbon disulphide or benzene; the alcoholic solution, on the addition of an excess of chlorine water or tincture of ferric chloride, becomes blue, changing quickly to green, the color being best seen when the solutions are diluted with an equal volume of water. A petroleum benzoin solution of Guaiac is colorless and yields no test for rosin with cupric acetate T.S." *N. F.*

"In masses, or sometimes in large more or less rounded tears. Brittle; fracture vitreous; thin splinters transparent, from yellowish-green to reddish-brown. Powdered Resin greyish, but becoming green on exposure to light and air. Odor, on warming, somewhat aromatic; taste slightly acrid. A solution in *alcohol* (90 per cent.) is colored blue by diluted *T. Sol. of ferric chloride.* 1 gramme of the powdered Resin, shaken for five minutes with 5 millilitres of *petroleum spirit,* yields a colorless filtrate which does not become green when shaken with an equal volume of *diluted solution of copper acetate* (absence of colophony). Not more than 10 per cent. insoluble in *alcohol* (90 per cent.). Ash not more than 4 per cent." *Br.*

The tincture is of a deep-brown color, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. It is colored blue by nitric acid, by chlorine, and by tincture of ferric chloride, and usually by spirit of nitrous ether, and is similarly changed when treated successively by diluted hydrocyanic acid and solution of copper sulphate. Either in substance or tincture, guaiac gives a blue color to gluten and substances containing it, to mucilage of gum arabic, to milk, and to various freshly cut roots, as to the potato, carrot, and horseradish. This is on account of the fact that oxidizing enzymes, or oxidases, are present in all of these substances and guaiac resin is one of the most delicate reagents for detecting this class of enzymes. It is soluble also in ether, alkaline solutions, and sulphuric acid. The solution in sulphuric acid is of a rich claret color, deposits, when diluted with water, a lilac precipitate, and, when heated, carbonizes. Exposed to air and light, guaiac absorbs oxygen and becomes green, and the change takes place rapidly in the sunshine. Schaer states that a good natural guaiac resin is preferable to a resin purified by alcoholic treatment as a reagent, but a solution of resin extracted by chloroform from the wood is the most sensitive of all. Tincture of guaiac has been used for the detection of blood stains, which it does by the blue color produced by it, when in contact with the red coloring matter of blood, in connection with some ozonized substance, especially hydrogen dioxide.

Adulterations.—Guaiac resin is sometimes adulterated with the rosin of the pine. The fraud may be detected by the terebinthinate odor exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves rosin, but leaves pure guaiac untouched. Amber was said to be another adulterant at one time. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue. Purgotti proposed guaiac resin as a test for copper. (See *A. J. P.*, June, 1880.)

Constituents.—Guaiac resin is made up chiefly of resin acids. (Lücker, *Proc. A. Ph. A.*, 1894.) Of these *guaiaconic acid,* $C_{20}H_{24}O_5$, which composes some 70 per cent. of the resin, occurs in two form known as alpha- and beta-guaiaconic acid. *Guaiaretic acid,* $C_{26}H_{24}O_4$, which is present in a little more than 11 per cent. is an optically inert, unsaturated acid. *Guaiac-betaresin* is present to the extent of about 15 per cent. Alpha-guaiaconic acid is colorless and amorphous, the beta variety, however, is crystalline. These acids are readily converted by oxidizing agents into a deep blue substance called *guaiac-blue,* which reaction is the bases of the guaiac test for blood (see under *diagnostic Tests,* Part II). There are present also small amounts of a coloring matter called *guaiac-yellow* and *guaiacic acid,* $C_{20}H_{24}O_4$, and traces of vanillin and a saponin. Guaiac beta-resin appears to be a decomposition product of guaiaconic acid and gives the blue reaction on oxidation.

On dry distillation guaiac resin yields *guaiacene,* C_5H_8O, guaiacol, creosol (see *Creosotum*), *guaiene* and finally *pyroguaiacin,* $C_{38}H_{44}O_6$ (according to Wiesner, $C_{18}H_{18}O_3$), in pearly scales, melting at 180° C. Guaiacene is the aldehyde of tiglic acid, $C_5H_8O_2$, and can be made synthetically from a mixture of acetaldehyde and propionaldehyde. Guaiene is 2:3-dimethyl naphthalene.

According to the experiments of W. Frieboes (*In. Dis.,* Rostock, 1903), the guaiac saponin (1 to 1000) forms a frothing solution which is persistent, is an excellent emulsifier, has the power to maintain in solution large proportions of sparingly soluble substances and is innocuous and non-irritant.

The mineral acids are incompatible with the solutions of guaiac.

Uses.—Guaiac, like many other resinous substances, is stimulant and alterative. If given to a patient when covered warm in bed, and accompanied with hot drinks, it may assist in exciting perspiration, and hence it has been ranked among the diaphoretics. In large doses it purges, and it has been especially commended as a laxative in *chronic rheumatism,* and it is thought by some practitioners to be possessed of emmenagogue powers. It has been given in *chronic rheumatism, gouty affections,* secondary *syphilis, scrofulous diseases,* and *cutaneous eruptions,* but is of doubtful service. The medicine is given in pill, emulsion or tincture.

An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. The ammoniated tincture of guaiac is a preparation of this kind. Several European Pharmacopœias direct a *soap of guaiac,* under the name of *sapo guaiacinus,* to be prepared by diluting solution of potassium hydroxide with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, which is followed by evaporating to the pilular consistence.

T. C. Craig (*A. J. P.*, July, 1880) recommends a *Syrup of Guaiac* made as follows: Powd. Guaiac Resin, 640 grains; Caustic Potassa, 58 grains; White Sugar, 1 lb. (av.); Water, q. s. Dissolve the Potassa in 8 fluidounces of water; moisten the Guaiac with this solution; pack it in a percolator, and gradually pour on the remainder of the solution; when this ceases dropping, add sufficient water to make the percolate measure 8 fluidounces; add the sugar, and dissolve.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

GUAIACOL. U. S., Br.

GUAIACOL

"A liquid consisting principally of $C_6H_4(OH)(OCH_3)$ 1 : 2, usually obtained from wood creosote, or a solid, consisting almost entirely of $C_6H_4(OH)(OCH_3)$ 1 : 2, usually prepared synthetically." *U. S.* "Guaiacol, $C_7H_8O_2$, may be prepared synthetically or obtained by the fractional distillation of beech tar creosote." *Br.*

Gaiacolum Methyl-orthodioxybenzene, Methyl-pyrocatechin, Catechol-monomethyl-ether; Gaïacol, *Fr. Cod.;* Guajacolum, *P. G.;* Guajakol, Brenzcatechin-monomethylester, *G.;* Guajocolo, *It.;* Guayacol, *Sp.*

Preparation.—Guaiacol is the monomethyl ester of the ortho-dioxybenzene known as catechol (pyrocatechin), and can be made from this diatomic phenol by methylating with the aid of methyl-sulphuric acid. It is, however, largely obtained from beechwood creosote, of which it constitutes from 60 to 90 per cent. The separation of the diatomic phenols and phenol-ethers from monatomic phenols in a mixture like creosote, is effected in several ways. The compounds formed by baryta with the former are much less soluble than those with the latter, and this is also true of magnesia compounds. Another method is to rub up the creosote with potassium carbonate. Guaiacol and creosol combine to form solid addition compounds, from which the other phenols are washed out with ether or petroleum benzin, when the crystalline mass is decomposed with water and the phenols separated. It is also prepared from ortho-nitrophenol by conversion into ortho-anisidine, a methylated derivative, as an intermediate step.

Description and Physical Properties.—"Liquid Guaiacol is colorless or yellowish. Solid Guaiacol is crystalline and is colorless or yellowish. Guaiacol becomes darker on exposure to light. When liquefied, the solid form may remain liquid for a long time even at a low temperature. Guaiacol has an agreeable, aromatic odor. One Gm. of Guaiacol is soluble in from 60 to 70 cc. of water and in 1 cc. of glycerin, at 25° C., but separates from the glycerin on the addition of water. It is miscible with alcohol, chloroform, ether, and with glacial acetic acid.

"Solid Guaiacol melts at about 28° C. The addition of a few drops of ferric chloride T.S. to 10 cc. of an alcoholic solution of Guaiacol (1 in 100) immediately produces a blue color, changing to emerald-green, and finally becoming yellowish.

"Specific gravity: liquid Guaiacol, not below 1.112 at 25° C.; melted solid Guaiacol, about 1.132 at 25° C. Not less than 85 per cent. of liquid Guaiacol distils between 200° and 210° C. when determined by Method II, page 000. Solid Guaiacol boils between 204° and 206° C. Ash: not more than 0.1 per cent. Shake 2 cc. of liquefied Guaiacol with 4 cc. of purified petroleum benzin; the mixture separates into two distinct, clear layers on standing. Permanent turbidity, or failure to separate into layers indicates the presence of impurities. One cc. of liquefied Guaiacol dissolves in 2 cc. of 15 per cent. potassium hydroxide solution when heated for one minute in boiling water; on cooling, the solution congeals to a nearly white mass. Much coloration or failure to congeal indicates the presence of impurities. The mass thus obtained forms a clear solution with 25 cc. of distilled water (*hydrocarbons*).

"Preserve in well-closed containers, protected from light." *U. S.*

"A colorless liquid, or colorless crystals melting at about 28° C. Characteristic, tarry odor; taste caustic, very pungent. Soluble in 80 parts of *water;* freely soluble in *alcohol* (90 per cent.), in *ether,* in *glycerin,* and in fixed oils. Liquid Guaiacol optically inactive; specific gravity 1.16 to 1.20. Distils between 200° and 205° C. A trace of *T. Sol. of ferric chloride* added to 25 millilitres of a solution (1 in 100) of Guaiacol in *alcohol* (90 per cent.) immediately produces a blue color which changes to emerald-green on the addition of more of the test-solution, and finally becomes yellowish. When liquid Guaiacol is shaken with twice its volume of *petroleum spirit* and allowed to stand, the mixture separates into well-defined layers which do not exhibit permanent turbidity. 1 millilitre of liquid Guaiacol dissolves when warmed with 2 millilitres of an aqueous solution (15 in 100) of *sodium hydroxide;* the nearly white mass which results on cooling yields a clear solution with 25 millilitres of *water* (absence of oily hydrocarbons)." *Br.*

S. Vreven (*Zeit. Oestr. Apoth. Ver.,* 1896, 711) recommended the following method for distinguishing between guaiacol and creosote: A drop of the liquid to be examined, 2 to 3 drops of ether, and 1 or 2 drops each of concentrated nitric and hydrochloric acids are well shaken together in a test tube. The mixture assumes at first a red-brown color, which is particularly evident in the ether layer; but upon spontaneous evaporation, well-formed needle-shaped crystals will separate out if guaiacol is present, the formation of these crystals being facilitated by occasional shaking, whereas in the presence of creosote oily globules only separate. While phenol gives a reaction similar to that of guaiacol, the crystals formed are easily distinguished from the needles produced by the latter.

Uses.—Guaiacol is locally irritant and somewhat anesthetic. Its germicidal power, although inferior to that of creosote, equals or perhaps surpasses phenol. It is absorbed readily, not only from the alimentary canal, but also through the skin. It is eliminated chiefly through the kidneys in combination with sulphuric and glycuronic acids. Although its general physiological action has not been carefully studied, it seems to resemble phenol, although less poisonous. Guaiacol is used internally chiefly as a stimulating expectorant in *phthisis* and *bronchitis.* It has been also largely used by endermic administration as an antipyretic in *pneumonia* and other *fevers,* but is liable to produce dangerous collapse. Locally it is employed for its anesthetic effects in various skin diseases as *herpes zoster, eczema, furunculosis,* and even minor operations in the nose and throat, and as an antiseptic in old *ulcers,* especially when *tubercular* or *leprous.*

For percutaneous administration from ten to twenty drops are gently rubbed on the abdomen and the surface covered with oiled silk.

Dose, from five to ten minims (0.3–0.6 cc.).

Off. Prep.—Petroxolinum Guaiacolis, *N. F.*

GUAIACOLIS CARBONAS. U. S. (Br.)

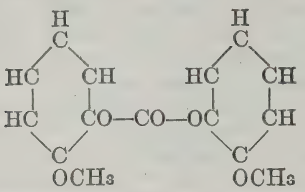
GUAIACOL CARBONATE Guaiacol. Carb.

"The guaiacol ester [$(C_6H_4(OCH_3)O)_2.CO$] of carbonic acid." *U. S.* "Guaiacol Carbonate, $(C_7H_7O)_2CO_3$, is the carbonic ester of guaiacol. It may be obtained by the interaction of carbonyl chloride with sodium guaiacolate." *Br.*

Guaiacol Carbonas, *Br.;* Duotal; Gaiacolum Carbonicum; Carbonas Guajacoli; Carbonate de Gaïacol, *Fr.;* Guajacolum Carbonicum, *P. G.;* Guajacolkarbonat, Kohlensaure-Gaujacyläther, *G.;* Carbonato de guayacol, *Sp.*

It is not a true carbonate in the sense that acids are capable of decomposing it with the evolution of CO_2. It is a carbonyl derivative and is prepared by the action of phosgene (carbonyl chloride) upon guaiacol in the presence of alkalies, or by combining guaiacol with methyl chloroformate.

The structural formula is:



Description and Physical Properties.—"Small, colorless crystals, or a white, crystalline powder. It is odorless and tasteless, or has a slight aromatic odor and taste. Guaiacol Carbonate is insoluble in water. One Gm. is soluble in 60 cc. of alcohol, 1 cc. of chloroform, and in 18 cc. of ether, at 25° C. It is freely soluble in boiling alcohol and benzene, and is slightly soluble in glycerin and in fixed oils.

"Guaiacol Carbonate melts between 85° and 88° C. Heat about 0.5 Gm. of Guaiacol Carbonate for a few minutes with 10 cc. of alcoholic potassium hydroxide T.S., cool, and decant the liquid from the precipitate; the addition of an acid to the precipitate produces effervescence. Evaporate the alcohol from the decanted liquid, strongly acidulate the residue with diluted sulphuric acid, and shake with chloroform; the separated chloroform layer upon evaporation leaves a residue which responds to the ferric chloride test for identity under *Guaiacol.*

"Ash: not more than 0.1 per cent. A saturated alcoholic solution of Guaiacol Carbonate is neutral to litmus paper, previously moistened with distilled water, and yields no bluish-green color on the addition of ferric chloride T.S. (*free guaiacol*). Dissolve 0.1 Gm. of Guaiacol Carbonate in 2 cc. of sulphuric acid; the solution is not darker than faint yellow (*readily carbonizable substances*)." *U. S.*

"A white crystalline powder, inodorous and almost tasteless. Insoluble in *water;* sparingly soluble in *alcohol* (90 per cent.), the solution being neutral to *litmus.* Melting point 85° to 88° C. When the liquid obtained by heating Guaiacol Carbonate with *N/20 solution of sodium hydroxide* is acidified, carbon dioxide is evolved and guaiacol is liberated. A saturated solution in *alcohol* (90 per cent.) does not assume a greenish or bluish color on the addition of *T. Sol. of ferric chloride* (absence of free guaiacol). No appreciable ash." *Br.*

Maue (*Ph. Ztg.,* 1918) proposes the following test for the identification of guaiacol carbonate: About 0.02 gramme of the sample is dissolved in 1 cc. of alcohol, 2 drops of ferric chloride solution and 1 drop of formaldehyde solution are added, and the mixture is poured on the surface of 2 cc. of sulphuric acid; a cherry-red coloration, due to the presence of guaiacol, develops at the junction of the two liquids. The sensitiveness of the reaction is about 1 : 300,000.

Uses.—Guaiacol carbonate is much used as a substitute for guaiacol on account of its comparative tastelessness and its lack of irritant properties. It is, however, much less effective than is guaiacol, both as a local and systemic drug. The experiments of W. Hesse (*D. M. W.,* 1898) indicate that when taken internally much of it passes through the alimentary canal unabsorbed.

Dose, from ten to twenty grains (0.65–1.3 Gm.).

GUARANA. N. F.

GUARANA

"Guarana is a dried paste consisting chiefly of the crushed seed of *Paullinia Cupana* Kunth (Fam. *Sapindaceæ*). Guarana yields not less than 4 per cent. of caffeine." *N. F.*

Paullinia, Brazilian Cocoa, Guarana Bread; Guarana, *Fr. Cod.;* Pasta Guaranæ; Guarana, *G., It.;* Paulinia, Pasta de Guarana, *Sp.*

There are described of the genus *Paullinia* 121 species, all of them confined in their geographical range to tropical and subtropical South America, except one, which has strayed to Eastern and Western Africa, and two others which are found in Mexico and in the gardens of the Sandwich Islands.

The *Paullinia Cupana* Kunth is a climbing shrub with alternate, imparipinnate leaves, which is native to the northwestern provinces of Brazil. The flowers are of yellowish color, growing in axillary spicate panicles. The leaves are long petioled, the leaflets being 5 to 6 inches long by 2 or 3 inches wide, and sinuate dentate on the margins. The fruit is ovoid or pyriform and about the size of a grape, and contains 1 to 3 seeds which resemble small horse chestnuts. They are lenticular and almost thorny and are invested with a flesh-colored arillus which is easily separable when dry.

It is probable that in the preparation of guarana the seeds of the allied species, *P. sorbilis* Martius, are used interchangeably with those of the official species.

Guarana is made exclusively by the Guaranis, a tribe of South America Indians, and probably varies in the details of its preparation, as it certainly does in appearance and quality. The drug appears to be produced almost exclusively from plants cultivated in the region of the lower Madeira and southward. After the seeds are shelled and thoroughly washed they are roasted for about six hours, and their external papery shells are then removed by placing them in sacks and beating them with clubs. The kernels are then broken in a mortar, the coarse powder is mixed with a little water, and then kneaded into a paste, which is shaped into cylindrical or globular masses; tapioca is sometimes added before kneading to increase plasticity. The lumps are dried, sometimes in the sun, or more usually by the heat of a slow fire so arranged as to avoid smoke. When finished, the masses are of a reddish-brown color, rugose on the surface, very hard, with an irregular fracture, and of a marble appearance when broken, due to the fragments of the seeds and their black testa embedded in the mass.

The present commercial supplies of guarana come to this country in cases from Para, Brazil.

Description and Physical Properties.—"*Unground Guarana.*—Usually in cylindrical sticks, about 3 to 5 cm. in diameter, externally dark reddish brown; hard and heavy, fracture uneven, often fissured in the center; internally pale reddish brown, showing more or less coarse fragments of seed and occasionally their blackish brown seed-coats. Odor slight; taste slightly astringent and bitter.

"*Powdered Guarana.*—Light pinkish brown; consisting mostly of irregular masses of parenchyma containing more or less altered starch grains; unaltered starch grains occasional, varying from spherical and polygonal to ellipsoidal and broadly ovoid, 0.010 to 0.025 mm. in diameter; occasional fragments with narrow, elongated sclerenchymatous cells; the walls being thick, yellowish and non-lignified.

"Place on a slide a drop of hydrochloric acid, add about 0.001 Gm. of powdered Guarana, then add a drop of gold chloride T.S. and allow the mixture to stand for a few minutes; beginning at the edge of the mount, crystals of caffeine and gold chloride separate in the form of orthorhombic plates and needles, the latter usually occurring in spheroidal aggregates and finally forming branching groups.

"**Assay.**—Place 6 Gm. of Guarana, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see Proximate Assays, Type Process A) during two hours. Allow the mixture to stand overnight, again shake intermittently during one-half hour, then allow the drug to settle. Decant, or filter off through a pledget of purified cotton, 100 cc. of the chloroformic liquid, representing 5 Gm. of Guarana, and evaporate it to dryness. Treat the residue with 10 cc. of weak (about 1 per cent.) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate strongly with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus, and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Guarana." *N. F.*

Guarana is of a somewhat astringent and bitterish taste, and in this, as well as in its odor, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. It is also partly soluble in alcohol.

Martius found in it a crystallizable principle, which he named *guaranine,* but which was later proved by Berthemot and Dechastelus to be identical with caffeine. Alexander Bennett, in an elaborate series of physiological experiments, confirmed this identity. According to Berthemot and Dechastelus, the caffeine exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble.

M. I. Wilbert (*J. A. Ph. A.,* 1914, 1286) reported a compilation of analyses of guarana comprising 41 samples in which the caffeine content varied from 3.72 to 5.16 per cent.

Rochefontaine and Gusset prepared caffeine by mixing one part of calcined magnesia with five parts of powdered guarana, moistening with water, and, after standing twenty-four hours, exhausting the mass with boiling chloroform, evaporating the chloroform, treating the residue with boiling water, filtering, and evaporating over sulphuric acid. (*A. J. P.,* 1886, p. 248.) F. V. Greene prefers a process for obtaining caffeine from guarana similar to one proposed by Wayne for its extraction from tea and coffee. See *U. S. D.,* 19th ed., p. 606.

F. V. Greene has shown that the tannic acid from guarana has different properties from that found in other plants, and proposes to call it *paullinitannic acid.* (*A. J. P.,* 1877, 390.)

Uses.—The effects of guarana upon the system are chiefly those of its alkaloid, although it contains enough tannin to have an appreciable influence. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water, precisely as other nations use teas, coffees, etc. It is also considered by the Indians useful in the prevention and cure of bowel complaints. It is now used in medicine almost exclusively to give relief during the paroxysm of *migraine,* and in atonic *chronic diarrhea,* taken three or four times a day.

Dose, of the powder, twenty to sixty grains (1.3–3.9 Gm.).

Off. Prep.—Fluidextractum Guaranæ, *N. F.;* Elixir Guaranæ (from Fluidextract), *N. F.;* Elixir Guaranæ et Apii (from Fluidextract), *N. F.*

GUMMI INDICUM. Br.

INDIAN GUM Ghatti Gum]

"Indian Gum is a gummy exudation from the stem of Anogeissus latifolia, *Wall.*" *Br.*

The genus *Anogeissus* (Fam. *Combretaceæ*) includes four or five different species of tropical trees. Of these *A. latifolia* is widely distributed in India and Ceylon. The tree is large and handsome, and one of the most useful of tropical India. The leaves are broadly elliptical, obtuse at the base and summit. They contain large amounts of tannin and are used in Bombay for tanning. The flowers are axillary and the fruit is 2-winged, being arranged horizontally into dense heads. The gum from this tree is collected in April and is used extensively in calico printing, especially in Lucknow. It may be distinguished from Acacia by its dull surface, uniform vitreous fracture and by the frequent presence of vermiform tears. Its mucilage is more viscid but less adhesive than Acacia and is usually used in connection with turmeric with which there is some specific combination.

The commercial supplies of this drug come from Bombay and London.

"In vermiform or rounded tears of varying size, colorless or pale yellow; surface dull, fracture vitreous. Slight odor; taste insipid and mucilaginous. Entirely soluble in *water,* forming a viscous, adhesive mucilage. Insoluble in *alcohol* (90 per cent.). The aqueous solution is gelatinised by the addition of *alcohol* (90 per cent.), or *solution of lead subacetate;* but it is unaffected by the addition of *T. Sol. of ferric chloride* or of *solution of lead acetate* (distinction from Amrad and certain other gums). It is not colored blue or brown by a small quantity of *N/10 solution of iodine* (absence of starch or commercial dextrin). Ash not more than 4 per cent. In India and the Eastern Divisions of the Empire, India Gum may be employed in making the official preparations for which Gum Acacia is directed to be used, one part of the former being taken for every two parts ordered of the latter (see 'Mucilago Gummi Indici')." *Br.*

Ghatti gum forms a nearly colorless mucilage with water which is more viscous than that made with a similar amount of acacia. Its aqueous solution gives a slight precipitate with solution of lead subacetate.

Uses.—Indian gum is used for the same purposes in pharmacy as acacia. It is well suited for pharmaceutical use, and is said to be specially valuable in the making of emulsions. It is insoluble in 90 per cent. alcohol.

The Br. Pharmacopœia allows of the substitution of India gum in official preparations in place of gum acacia, with the statement that one part of it should be substituted for two of the acacia. It must not be confounded with either Bassora or Gum Sterculin, each of which is sometimes referred to as "Indian Gum." (See Part II.)

Off. Prep.—Mucilago Gummi Indici, *Br.*

HÆMATOXYLON. N. F. (Br.)

HEMATOXYLON Hæmatox. [Logwood]

"Hematoxylon is the heart-wood of *Hæmatoxylon campechianum* Linné (Fam. *Leguminosæ*). Hematoxylon contains not more than 2 per cent. of foreign organic matter." *N. F.*

"Logwood is the heart-wood of Hæmatoxylon campechianum, *Linn.*" *Br.* "The heart-wood of *Hæmatoxylon campechianum* Linné (Fam. *Leguminosæ*) that has not undergone fermentation." *N. F.*

Hæmatoxyli Lignum, *Br.;* Lignum Campechianum, Lignum Cœruleum; Bois de Campêche ou Bois d'Inde, Bois de Sang, *Fr.;* Blauholz, Campecheholz, Blutholz, Kampeschenholz, *G.*

Hæmatoxylon campechianum is a tree of medium height with crooked trunk covered with dark rough bark. The branches are beset with sharp spines and show many white lenticels. The sap-wood is yellowish, but the interior layers are of a deep-red color. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odor, said to resemble that of the jonquil.

The tree is a native of Campeche, the shores of Honduras Bay, and other parts of tropical America, and has become naturalized in Jamaica. It is cultivated in tropical America and Asia. The heartwood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood and having a purplish-red to blackish-brown color externally. Logwood is imported from Campeche, Honduras, from San Domingo and Jamaica. That from Campeche is considered the best, while Jamaica logwood is poorest in tinctorial properties. According to Louis Siebold, the ground or chipped logwood of commerce is unfit for use as a medicinal agent, because it has been prepared as a dyestuff by being exposed in large moist heaps until its hematoxylin has been converted by oxidation into hematein. As a coloring agent, for commercial purposes, this fermented logwood, according to Siebold, is much superior to the natural wood. An inferior variety of logwood which contains little or no hematoxylin, but a pure yellowish-gray dye is that known as *bastard logwood.* According to the researches of E. S. Earl this bastard logwood is produced by a variety of the species, which, when growing, cannot be distinguished from the ordinary form. (*B. D. A. J.*, i, 31.)

Logwood is hard, compact, heavy, of a deep-red color, becoming purplish-black by exposure, internally brown-red, and marked with irregular, concentric circles, and splitting irregularly.

Description and Physical Properties.—"*Unground Hematoxylon.*—Usually in small chips, occasionally in billets reddish brown, the freshly cut surface dark yellowish red. Odor faint, agreeable; taste sweetish, astringent.

"*Structure.*—Composed of irregular, concentric zones of yellowish, thick-walled wood fibers and crystal fibers alternating with porous wood parenchyma, the latter surrounding tracheæ either isolated or in groups of two, rarely three; the entire tissue radially traversed by parallel medullary rays, the latter 1 to 7 cells in width.

"*Powdered Hematoxylon.*—Reddish brown; numerous fragments of tissue composed of wood fibers and crystal fibers, the latter with monoclinic prisms of calcium oxalate from 0.010 to 0.030 mm. in length; tracheæ from 0.080 to 0.170 mm. in diameter with bordered or simple pores and containing a reddish brown amorphous content; fragments of tissue of medullary rays, the walls of the cells with simple pores." *N. F.*

"Hard, heavy, dull orange to purplish-red externally and reddish-brown internally. In transverse section, alternating yellowish-brown and dark brown wavy tangential lines. In the form of chips or coarse powder, it is free from signs of fermentation, and from green metallic lustre. Slight, agreeable odor; taste sweetish, astringent. Readily imparts a reddish-violet color to *water* made slightly alkaline with *solution of sodium hydroxide.*" *Br.*

Its solution affords precipitates with sulphuric, nitric, hydrochloric, and acetic acids, alum, copper sulphate, lead acetate, and ferrous sulphate, giving a bluish-black color with the last mentioned salt. Precipitates are also produced with it by lime water and gelatin.

Chevreul found in logwood, a volatile oil, an oleaginous or resinous matter, and a peculiar principle called *hematoxylin* or *hematin* (which must not be confused with the hæmatin of the blood), on which the coloring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture until it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are shining, of a yellowish-rose color, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdmann, who obtained hematoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are colorless, without a tinge of redness; its taste is sweet, like that of licorice, without bitterness or astringency; and it is not of itself a coloring substance, but affords beautiful red, blue, and purple colors, by the joint action of an alkaline base and the oxygen of the air. He obtained from logwood 9 to 12 per cent. of crystallized hematoxylin, to which he gave the formula $C_{16}H_{14}O_6$. It crystallizes with 1 or with 3 molecules of water, and is readily soluble in hot water or alcohol, but sparingly in cold water or in ether. (*J. Pr. Chem.*, xxxvi, p. 205.) Commercial extract of logwood extracted from the wood by boiling water contains both hematoxylin and *hematin*, as the former is changed to the latter by oxidation. The proportion of *hematin* is about one-fourth that of the *hematoxylin.* There are "hematin" pastes in the color trade in which the conversion is almost complete, about 90 per cent. hematin being present. Hematoxylin, in alcoholic solution, is used as an indicator in the U. S. P. X. (See *Hematoxylin Test-solution,* Part III.)

Uses.—Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of the bowels which is apt to succeed *cholera infantum.* It is also occasionally used with advantage in ordinary *chronic diarrhea* and *chronic dysentery. Hematoxylin* was found by Combemale (*B. M. N.*, xxxiii, 1894) to be very feebly antiseptic, but capable in large doses of producing fatal gastro-enteritis in the lower animals. It is used not only as a dye-stuff but also as a microscopical stain.

Dose, from ten to thirty grains (0.65–1.9 Gm.).

Off. Prep.—Decoctum Hæmatoxyli, *Br.;* Extractum Hæmatoxyli, *N. F.*

HAMAMELIDIS CORTEX. Br.

HAMAMELIS BARK [Witchhazel Bark]

"Hamamelis Bark is the dried bark of Hamamelis virginiana, *Linn.*" *Br.*

Hamamelidis Cortex, *U. S. VIII;* Witchhazel, Spotted Hazel, Striped Alder, Snapping Hazel, Winterbloom; Ecorce de Hamamelis, *Fr. Cod.;* Hamamelis, Zauberhasel, *G.;* Hamamelis (Corteza de), *Sp.*

This bark was deleted from the U. S. P. IX, but retained by the *Br.* and *N. F.*

Witchhazel is an indigenous shrub or a small tree, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is the only species of the genus found in eastern North America, occurring from New Brunswick to Minnesota and southward to Florida and Texas. Schneider asserts that it has been introduced into California and that it is extensively cultivated in this locality. It is specifically characterized by its leaves being obovate or oval, wavy-toothed, and somewhat downy when young. The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. It is remarkable for the late appearance of its yellow flowers, which expand in October and November and continue until the weather becomes very cold in winter. The fruit is a 2-beaked, 2-celled woody capsule, each cell containing a single black seed. It ripens in October and November at the same time the blossoms appear and is in each instance the product of a blossom of the previous year.

Properties.—The bark occurs "in curved or channelled pieces about one and a half millimetres thick, and from one-half to two decimetres long, sometimes covered with a silvery-grey or dark-grey scaly cork marked with transverse lenticels, but frequently freed from the cork, and then exhibiting a nearly smooth reddish-brown outer surface. Inner surface pale reddish-pink, and finely striated longitudinally; fracture laminated and coarsely fibrous. In transverse section, a cortex containing prismatic crystals of calcium oxalate, a complete ring of sclerenchymatous cells, and numerous tangentially elongated groups of bast fibres. No marked odor; taste astringent." *Br.*

Holm (*Merck's Rep.*, xxi, p. 5) has written an illustrated paper on the morphology of hamamelis.

Walter B. Cheney examined witchhazel bark, and found tannin, resin, extractive, but no indication of an alkaloid or other crystalline principle. (*A. J. P.*, 1886, p. 418.) It contains a trace of volatile oil however.

Uses.—The bark of the witchhazel is said to have first attracted attention on account of its use by the North American Indians as a sedative application to external inflammations. Professional attention was strongly directed to the remedy on account of the enormous sale of a much vaunted proprietary remedy said to be made by distilling the bark with very dilute alcohol (six per cent.), and used externally for *sprains* and *bruises*, and internally for most of the diseases to which flesh is heir. The large use of this preparation led to the recognition by both the British and American Pharmacopœias of a distillate of hamamelis bark; this has however been dropped by the U. S. P. (see *Liquor Hamamelidis*), as whatever slight therapeutic virtue as witchhazel possesses seems to depend on its tannin, it is obvious that this distillate cannot represent the drug.

Dose, of the bark, thirty grains (2 Gm.).

Off. Prep.—Tinctura Hamamelidis, *Br.*

HAMAMELIDIS FOLIA. N. F., Br.

HAMAMELIS LEAVES Hamamel. Fol. [Witchhazel Leaves]

"Hamamelis Leaves consists of the dried leaves of *Hamamelis virginiana* Linné (Fam. *Hamamelidaceæ*). Hamamelis Leaves contain not more than 5 per cent. of stems or other foreign organic matter." *N. F.*

"Hamamelis Leaves are the fresh or dried leaves of Hamamelis virginiana, *Linn.*" *Br.*

Hamamelis, *U. S. 1890;* Folia Hamamelidis; Hamamélis de Virgine, *Fr. Cod.;* Feuilles de Hamamelis, *Fr.;* Witchhazel, Witch Hazel Leaves; Hoja de Hamamelis, *Sp.*

For description of this plant see *Hamamelidis Cortex.*

Description and Physical Properties.—"*Unground Hamamelis Leaves.*—Petiole from 1 to 1.5 cm. long; lamina when entire broadly elliptical or rhomboid-ovate, usually inequilateral, mostly from 8 to 12 cm. long, apex usually acute, sometimes rounded or acuminate; base slightly heart-shaped and oblique; margin sinuate or sinuate-dentate; upper surface pale or brownish green, with a few stiff hairs; lower surface lighter in color, somewhat hairy, midrib and veins prominent, the secondary veins running straight to the margin. Odor slight; taste astringent, slightly aromatic and bitter.

"*Structure.*—Epidermal layer prominent; a palisade layer consisting of a single row of cells; a spongy parenchyma tissue made up of three to six rows of strongly branching cells; large collateral, fibro-vascular bundles in the midrib and petiole, the tracheæ narrow, mostly spiral and associated with numerous narrow, strongly lignified and porous wood fibers; around the phlœm a nearly continuous circle of bast fibers, the latter with strongly lignified walls and associated with crystal fibers.

"*Powdered Hamamelis Leaves.*—Numerous fragments of epidermal tissue showing narrowly elliptical stomata from 0.023 to 0.035 mm. in length and with 2 to 4 neighboring cells; numerous stellate hairs composed of from 4 to 12 cells united at the base, the individual cells usually curved, with thick walls, narrow lumina and from 0.050 to 0.500 mm. in length; numerous fragments of tracheæ associated with strongly lignified, porous wood fibers; calcium oxalate in monoclinic prisms from 0.010 to 0.035 mm. in length in cells of the mesophyll or in crystal fibers associated with bast fibers." *N. F.*

The British Pharm., 1914, describes the leaves as follows: "Broadly oval in outline, from seven to fifteen centimetres long. Upper surface dark green or brownish-green, under surface paler; apex obtuse, margin sinuate; narrowed towards the base, oblique, slightly cordate, and shortly petiolate. Veins pinnate and prominent on the under surface, where they are furnished with stellate hairs. No marked odor; taste astringent and slightly bitter." *Br.*

The microscopical characteristics of the hamamelis leaves have been described by Hans Kramer in *B. P. G.*, xvii, p. 323.

Uses.—Witchhazel leaves contain a small amount of tannin and probably also a bitter principle, although we know of no careful analysis. The fluidextract is used chiefly as an astringent local application in *varicose veins, hemorrhoids, sore throat* and *chronic catarrhs.*

Dose, fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Fluidextractum Hamamelidis Foliorum, *N. F.* (*Br.*); Liquor Hamamelidis, *Br.;* Unguentum Hamamelidis (from Liquid Extract), *Br.*

HELONIAS. N. F.

HELONIAS Helon. [False Unicorn]

"Helonias consists of the dried rhizome and roots of *Chamælirium luteum* (Linné) A. Gray (Fam. *Liliaceæ*). Helonias contains not more than 5 per cent. of foreign organic matter." *N. F.*

Starwort; False Unicorn Root; Devil's Bit; Blazing Star.

Because of the fact that the English name of "Unicorn Root" has been applied to this plant as well as to the Aletris, there has been considerable confusion and rhizomes and roots of these plants are often substituted one for the other, although they are neither botanically nor therapeutically closely related.

The *Chamælirium luteum* (L.) A. Gray (*C. carolinianum* Willd., *Helonias dioica* Pursh.) is a native diœcious herb with a smooth stem 1 to 4 feet in height terminating in a spiked raceme of white flowers. The stem leaves are lanceolate and the basal leaves spatulate.

The rhizome and roots are used in medicine. They somewhat resemble those of Aletris but all of the rootlets of Helonias are whitish or pale yellowish, none exhibiting a reddish-brown external color through abrasion, nearly straight, and of a bitter, slightly astringent taste. (See *Aletris.*)

Description and Physical Properties.—"*Unground Helonias.*—Rhizome upright, or oblique, sometimes nearly cylindrical, from 0.5 to 3 cm. long and about 1 cm. in diameter; externally grayish brown; annulate from scars of bud-scales; upper portion with leaf-bases enclosing a small bud; oblique rhizomes with a few stem-scars up to 7 mm. in diameter; lower portion with numerous whitish or pale yellowish, slightly curved, wiry roots, from 5 to 8 cm. long, arising from deep pits in the rhizome and with cortex usually detached; fracture hard and horny; internally grayish yellow, cortex from 3 to 4 mm. thick. Odor slight; taste bitter, slightly astringent.

"*Structure.*—Rhizome; cork cells with lignified walls and with a brownish amorphous content; a wide cortical parenchyma layer through which extend, outwardly from the central cylinder, numerous lateral roots emerging from the base of deep cylindrical pits which extend inwardly from the surface of the rhizome; central cylinder made up of three or four irregular circles of fibrovascular bundles, the latter separated by parenchyma cells and from 0.200 to 0.300 mm. in diameter. Root; cortex composed chiefly of more or less collapsed parenchyma cells containing starch grains; a distinct endodermis of radially elongated cells with lignified walls; a central cylinder usually composed of from 5 to 7 vascular bundles.

"*Powdered Helonias.*—Light yellowish; numerous fragments composed of parenchyma cells containing altered or unaltered starch grains, the latter being spheroidal or ellipsoidal and up to 0.015 mm. in diameter; raphides of calcium oxalate chiefly in bundles, the individual crystals from 0.025 to 0.040 mm. in length; fragments of lignified cork tissue; numerous fragments of tracheæ tissue assocated with more or less lignified fibers; tracheæ with simple pores, scalariform or reticulate markings." *N. F.*

The Helonias root contains approximately 9.5 per cent. of a saponin first separated by Kruskal (*Arbeiten d. Pharmacol. Inst. zu Dorpat.*, 1891, vi) and by him named *chamælirin.* This is one of the least toxic of the saponin bodies; according to Kruskal 0.427 Gm. per kilo of pure chamælirin injected intravenously is not sufficient to kill a cat.

Helonin is a term used by the eclectics to define the alcoholic extract found in commerce.

Uses.—Large doses of Helonias are nauseant, probably from the local irritant action of its characteristic saponin. It is by some supposed to have a tonic action upon the uterus and used in *amenorrhea, dysmenorrhea* and *leucorrhea.* It has also been used as an anthelmintic. Its value, however, is very doubtful.

Dose, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Fluidextractum Heloniadis, *N. F.;* Elixir Aletridis Compositum, *N. F.;* Elixir Heloniadis Compositum, *N. F.*

HIRUDO. Br.

LEECHES

"Leeches are (1) Hirudo medicinalis, *Linn.*, the Speckled Leech, and (2) Hirudo quinquestriata, *Schmarda,* the Five-striped or Australian Leech." *Br.*

Sangsue, *Fr. Cod.;* Hirudines, Blutegel, *G.;* Sanguisuga, Mignatta, *It.;* Sanguijuela, *Sp.*

Leeches are highly specialized fresh water, marine or terrestrial Annelids devoid of setæ or parapodia and possessing anterior and posterior suckers. They belong to the Class *Hirudinea,* a group of *Annelida* characterized by the possession of 33 body segments, 2 suckers, one of which is around the mouth and the other at the posterior end and the absence of bristle-like appendages (setæ) except in a single genus. All are hermaphroditic, but the eggs of one animal are fertilized by the spermatozoa of another. There are three groups of leeches, depending upon their habits. (1) Temporary parasites which include most of this group of animals and are found in cold seas. (2) A group of nearly permanent parasites which are found in both temperate and tropical regions. (3) A group of predatory hunters or scavengers which are confined to warm regions. These groups may change from one mode of life to another. Four families are usually distinguished and commonly designated as fish leeches; tortoise and snail leeches; worm leeches; and jawed leeches. The latter include the *Hirudinidæ,* which are distinguished in that they have no proboscis and generally possess three-toothed jaws. The true blood-sucking leeches, the medicinal leeches of Europe, belong to this group.

The leech is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the posterior one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the center of the anterior disk, and is furnished with three cartilaginous jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine, sharp, chitinous teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the ventral surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglia. The intestinal canal is straight, and terminates in the anus, near the posterior disk. The eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss or in moistened earth, and is frequently transported in this manner to great distances without injury.

Savigny has divided the genus *Hirudo* of Linnæus into several genera. The true leech is the *Sanguisuga* of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points. Several species are used for medicinal purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus, and the *Hirudo decora* of this country.

1. *Hirudo medicinalis* Linn. (*Sanguisuga officinalis* Savigny. *The green* or *gray leech.*—This leech is marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tessellated with black spots. The color of the back varies from a blackish to a grayish-green. The belly in the one variety is of a yellowish-green color, free from spots, and bordered with longitudinal black stripes. In the second variety it is of a green color, bordered and maculated with black. This leech varies from two to four inches in length. It inhabits marshes and running streams, and is abundant throughout Europe. A variety of the leech has come into use in Europe, called in commerce, *African leeches.* They are of a beautiful light green color, varying to a deep green, and often inclining to red, with black points on the back, and broad streaks of a bright orange yellow, which are black towards the abdomen. They correspond perfectly with the *Sanguisuga interrupta* of Moquin-Tandon. These leeches draw very well. (*P. J.*, x, 38.) The leeches from Algiers, called in French commerce, *dragons* (*Sanguisuga troctena* of Moquin-Tandon), of which considerable numbers have been taken to France, are said by M. A. de Quatrefages, contrary to former opinion, to be quite equal to the European. (*J. P. C.*, 3e sér., xxxiii.)

2. *Macrobdella* (*Hirudo*) *decora* Say, the medicinal leech of America, has a back of a deep pistachio-green color, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange color. The belly is of the latter color, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood. *Hirudo quinquestriata* Schmarda (*Hirudo australis* Bosisto; *Limnobdella quinquestriata* R. Blanch), the *five-striped* or *Australian leech,* has a dorsal surface greenish-yellow-brown, with five longitudinal stripes, the ventral surface being greenish-yellow and not spotted. The jaws are large, with forty-eight to fifty teeth, the inner being the larger.

The great use formerly made of leeches in the practice of medicine, occasioned them to become a considerable article of commerce. They were collected in Spain, France, Italy, Germany, and Sweden, and carried in large numbers to London and Paris. They were also frequently brought to this country, as the practitioners in some of our large cities used only the foreign leeches, although our own waters furnish an inexhaustible supply.

The British Pharm. (1914) gives the following description: "Body soft, smooth, five centimetres or more long, tapering to each extremity, plano-convex, marked with from ninety to one hundred fine annulations. Anterior extremity terminated by a small sucker surrounding the tri-radiate jaws, the posterior extremity by a large sucker. (1) Speckled Leech: dorsal surface olive-green, with six longitudinal stripes; ventral surface greenish-yellow, with black spots. (2) Five-striped Leech: dorsal surface greenish-brown, with five longitudinal stripes; ventral surface greenish-yellow, not spotted." *Br.*

The proper preservation of leeches is an object of importance, as they are liable to a great and sudden mortality. They are usually kept in jars, in clear, soft water, which should be changed twice a week in winter and every other day in summer. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time and continue active and healthy without any other attention than that of frequently changing the water in which they are kept. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much or preventing the water from freely penetrating them. At one end of the trough, and about midway of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes, and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin and is a principal cause of its disease and death. James Banes recommends that when kept in jars they should be cleansed by means of a whisk of very fine broom or willow, when the water is changed. Lahache, an apothecary at Bruyères, stongly recommends carrageen, or Irish moss (*Chondrus crispus*), as admirably adapted to the habits and wants of the leech, furnishing the animal, he supposes, with nutriment, as it does not die of inanition when thus kept. The water should be renewed in the jars daily. (*J. P. C.,* 4e sér., iii, 128.) Alfred Allchin keeps them in aquaria with growing water-plants and snails, which keep the water pure. For other methods of keeping leeches, also of raising them, see *U. S. D.,* 14th ed., 472.

Uses.—Leeches afford the least painful and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation, or from their great tenderness when inflamed, do not admit of the use of cups. They are now used much less often than formerly.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a small hole in a piece of blotting paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off. As a very efficient mode of applying leeches, it is recommended, after having moistened the skin with pure warm water, to put the leeches into a tumbler half full of cold water, and by an adroit movement invert it upon the part. The leeches are said to attach themselves so rapidly that it seems to the patient as though they made but a single bite. When they are all attached, the glass is to be carefully removed, the water being absorbed, as it runs off on one side, by a sponge or linen cloths. As a rule, our leeches apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off, the same application will make them disgorge the blood they have swallowed. The practice of using over again leeches which have been made to disgorge the blood they have sucked is to be condemned on account of the danger of carrying infection from one patient to another. In cases where the bleeding from leech bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, by the use of collodion, or by touching the wounds with lunar caustic or other styptic.

In 1884 Haycraft showed that the saliva of the leech prevented the coagulation of the blood. This is due to the action of a secondary albumose known as *herudin* (*hirudin* is a commercial name for a preparation manufactured from leech heads the precise nature of which is not revealed, see Part II). Although Rimann and Wolff found that it required twenty milligrammes to render one hundred grammes of human blood non-coagulable, Satterlee and Hooker found that as small an amount as three and a half milligrammes per hundred grammes, caused perceptible retardation of clotting. The anticoagulant properties of leech extract, or its active principle, have been of much value in the physiological laboratory. Leech extract may be prepared according to the following method which is a modification of that suggested by Franz: cut off the leech heads, mince them, rub up with a very fine sand, add to the mass 5 cc. of physiological salt solution for each leech head and heat for 20 minutes at a temperaure of 100° C., allow to macerate for twelve hours, decant off the liquid, wash the sand several times with physiological salt solution, unite the liquids and filter through cheesecloth. This solution, which is suitable for some laboratory purposes, is not gauged by the quantity of solution, but by the number of leechheads represented. According to Franz, it requires three leeches per kilo body weight to prevent coagulation of the blood in the dog. Preference to-day, however, is generally given to hirudin. This has been used not only in the physiological laboratory, but in clinical medicine for the purpose of preventing clotting during transfusion of blood. Marshall (*J. P. Ex. T.,* 1915, vii, 157) has found that commercial samples of hirudin may be highly toxic, apparently from contamination with some product of putrefaction. (For details of technique and extensive literature on the whole subject see article of Satterlee and Hooker, *J. A. M. A.*, 1914, lxii, p. 1781.) On the theory that *eclampsia* was due to excessive fibrin content of the blood, hirudin has been suggested as a therapeutic measure in this condition.

HOMATROPINÆ HYDROBROMIDUM. U. S., Br.

HOMATROPINE HYDROBROMIDE Homatrop. Hydrobr. [Homatropine Bromide, Homatropine Hydrobromate]

"The hydrobromide [$C_{16}H_{21}O_3N.HBr$] of a synthetic alkaloid prepared from tropine and mandelic acid." *U. S.* "Homatropine Hydrobromide, $C_{16}H_{21}NO_3$,HBr, is the hydrobromide of an alkaloid prepared from tropine." *Br.*

Bromhydrate d'Homatropine, *Fr.;* Homatropinum hydrobromicum, *P. G.;* Homatropinhydrobromid, Bromwasserstoffsaures Homatropin, Bromwasserstoffsaures Oxytoluyltropein, *G.*

Preparation.—This alkaloidal salt was first admitted to the British Pharmacopœia in the additions of 1890. Homatropine, $C_{16}H_{21}NO_3$, is prepared by evaporating a mixture of tropine, $C_8H_{15}NO$ (obtained through the hydrolysis of hyoscyamine), and *mandelic acid* (phenylglycollic), $C_6H_5.CH(OH)COOH$, with diluted hydrochloric acid; mandelic acid may be produced by acting on amygdalin with hydrochloric acid, or synthetically from benzaldehyde and hydrogen cyanide.

Description and Physical Properties.—"White crystals or a white, crystalline powder. It is odorless. *Caution.—Homatropine Hydrobromide is extremely poisonous.* One Gm. of Homatropine Hydrobromide is soluble in 6 cc. of water, 40 cc. of alcohol, and in 420 cc. of chloroform, at 25° C. One Gm. is soluble in 12 cc. of alcohol at 60° C. It is insoluble in ether.

"It melts at about 212° C. with partial decomposition. Iodine T.S. produces in an aqueous solution of Homatropine Hydrobromide a brown precipitate; silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid. Shake 2 cc. of chloroform with 1 cc. of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine T.S. have been added: the chloroform acquires a brownish color. Add a slight excess of ammonia T.S. to 1 cc. of an aqueous solution of the salt (1 in 100), shake it with chloroform, and evaporate the chloroform solution to dryness on a water bath: the residue becomes yellow and finally brick-red when warmed with about 1.5 cc. of a solution made by dissolving 1 Gm. of mercuric chloride in 50 cc. of a mixture of 5 volumes of alcohol and 3 volumes of distilled water (*difference from most other alkaloids except atropine and hyoscyamine*).

"Its aqueous solution (1 in 20) is neutral to litmus paper. The ash from 0.1 Gm. is negligible. One cc. of an aqueous solution of the salt (1 in 20) is not precipitated by tannic acid T.S. Another 1 cc. portion acidulated with hydrochloric acid yields no precipitate with platinic chloride T.S. (*difference from most other alkaloids*). Add 5 drops of nitric acid to about 0.01 Gm. of Homatropine Hydrobromide, and evaporate to dryness in a porcelain dish on a water bath: the residue does not become violet on the addition of a few drops of alcoholic potassium hydroxide T.S. (*atropine, hyoscyamine or scopolamine*)." *U. S.*

"White crystalline powder, or aggregations of minute crystals. Soluble in about 6 parts of *water*, and in about 18 parts of *alcohol* (90 per cent.), the solutions being neutral to *litmus*. Yields the *reactions* characteristic of bromides. An aqueous solution (1 in 100) applied to the eye powerfully dilates the pupil. 1 millilitre of this solution made alkaline with *solution of ammonia*, shaken with *chloroform*, the chloroformic solution being then separated and evaporated, yields a residue which turns first yellow and then brick-red when warmed with 1.5 millilitres of a solution (2 in 100) of *mercuric chloride* in *alcohol* (60 per cent.). When treated with *nitric acid* and *alcoholic solution of potassium hydroxide* as described under 'Atropina,' a reddish-yellow color is produced, not changing to violet (distinction from atropine)." *Br.*

Uses.—Homatropine is used in medicine solely as a mydriatic and cycloplegic. Its effects upon the eye are, like those of atropine, due to a paralyzing action upon the peripheral ending of the oculo-motor nerve. It has the advantage over atropine in being relatively much less toxic to the general system and of being somewhat quicker in its action. It has in the past been stated that homatropine had no depressant effect upon the pneumogastric nerve, indeed that it slowed the pulse, but Zulick has shown (*J. P. Ex. T.*, 1915, vi, 473) that its effects upon cardiac inhibition are similar in kind to those of atropine, although it requires very large doses to affect the circulation. Occasionally unpleasant symptoms have followed the instillation of homatropine solutions into the eye, but we know of no fatal case of homatropine poisoning.

After the instillation of a 1 per cent. solution the pupil begins to dilate in from seven to twenty minutes and accommodation fails in forty to ninety minutes, while recovery is usually complete in three to four days. For simple dilatation of the pupil a 1 per cent. solution is sufficient, but when it is desired to paralyze accommodation completely a 2 per cent. solution may be employed.

Dose, internally, from one one-hundredth to one-fiftieth of a grain (0.0006–0.0013 Gm.).

Off. Prep.—Lamellæ Homatropinæ, *Br.*

HUMULUS. N. F.

HOP Humul.

"Hop is the carefully dried strobile of *Humulus Lupulus* Linné (Fam. *Moraceæ*) bearing its glandular trichomes. Hop contains not more than 2 per cent. of stems, leaves or other foreign matter, and yields not more than 5 per cent. of acid-insoluble ash." *N. F.*

Lupulus, *Br. Pharm.* 1898; Hop; Strobili Humuli, Fructus Lupuli; Houblon, *Fr. Cod.;* Hopfen, *G.;* Luppolo, *It.;* Lupulo (Fruto de), Hombrecillo, *Sp.*

The hop plant is a twining, rough perennial having angular, rough, flexible stems, which twine around neighboring objects in a spiral direction from left to right, and climb to a great height. The leaves are opposite, and long petioled. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green color on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the petioles are two to four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and bracteate. The staminate flowers are a yellowish-white, and arranged in panicles; the pistillate, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears, near its base, on its inner surface, two flowers, consisting of a roundish compressed ovary, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small achenes, surrounded by a yellow, granular powder—so-called "lupulin. Only the pistillate plants are cultivated by the hop growers in Europe, and it is interesting to note that the unfertilized pistillate plants produce strobiles richer in aroma and more plenteous in lupulin. The plants flower in August and the fruits are harvested during September. The hops grown in this country contain a great many achenes, showing that the staminate plants are also cultivated. The strobiles are collected when the scales change from a light golden to a somewhat deeper hue.

The hop plant is a native of North America and Europe. In parts of New England, New York, Michigan and Indiana, it is extensively cultivated, and most of the hops consumed in the United States is supplied by those districts. Hops are also cultivated in Europe, Australia and South America. The part of the plant used is the fruit or strobiles. These, when fully ripe, are picked, dried by artificial heat, packed in bales or hemp bags, and sent into the market.

By separating the volatile oils and determining its acid and ester value, Rabak (*C. D.*, lxxxv, 376) is able to distinguish American grown from imported hops. He finds that the European hops always show a lower ester value in the volatile oil than do the American.

Hops consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow color, and contain near the base two small, round, black achenes. They are

Description and Physical Properties.—"*Unground Hop.*—Strobile ovoid-cylindrical, about 3 cm. in length, consisting of a narrow, hairy, flexuous rachis and numerous, imbricated, yellowish green, obliquely ovate, membranous scales, the base of each with numerous, yellowish brown glandular hairs, and frequently infolded on one side, enclosing a subglobular, light brown, very glandular achene. Odor strong and characteristic becoming disagreeable and valerian-like on aging; taste aromatic and bitter.

"*Powdered Hop.*—Light yellowish green; numerous fragments of wavy-walled lignified epidermal tissue; fragments of parenchyma tissue with many of the cells containing calcium oxalate in rosettes and associated with branching tracheæ, the latter having spiral markings; numerous unicellular, slightly curved non-lignified hairs with walls frequently silicified, occurring either isolated or attached to fragments of epidermal tissue; numerous rosettes of calcium oxalate up to 0.024 mm. in diameter; glandular hairs with multi-cellular heads filled with yellowish oil from 0.100 to 0.300 mm. in diameter or frequently broken (*lupulin*); few glandular hairs with nearly colorless multi-cellular heads; few spherical, spinose yellowish pollen grains up to about 0.024 mm. in diameter; a few lignified fibers; few fragments of parenchyma tissue with large cells containing cystoliths of calcium carbonate.

"Preserve Hop in tightly closed containers, protected from light." *N. F.*

Though brittle when quite dry, they are pulverized with great difficulty. Their odor is strong, peculiar and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction, but the first mentioned property is dissipated by long boiling. The most active part of hops is the lupulin (see *Lupulinum*).

Hops are often subjected in Germany to the fumes of burning sulphur, because of the supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Heidenreich, who puts twenty or thirty strobiles of the hops in a flask with zinc and hydrochloric acid, and passes the hydrogen evolved through solution of lead acetate. If sulphurous acid be present, hydrogen sulphide will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by R. Wagner. For the solution of lead acetate used in Heidenreich's method there is to be substituted a solution of sodium nitroprusside, so weak as to have a very light brown color, to which have been added a few drops of solution of potassium hydroxide. If the gas evolved contain the minutest proportion of sulphur, a violet color will be produced when the first bubble passes into the solution; and this will, by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found, but a few months after the sulphuring of hops none at all can be detected.

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken; and any parcel presenting this appearance is to be suspected. Hops often contain a variable quantity of lupulin in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value and not be used medicinally.

Constituents.—Hops contain two crystallizable bitter substances of an acid character, and three resins, two of which are soft in character and bitter in taste and are present to the extent of over 10 per cent., and one of which is hard in character and tasteless and present to the extent of less than 5 per cent. The two soft resins probably contribute the most valuable properties of the hops, although the insoluble bitter acids, according to some authorities, are hydrolized in preparing the wort and become bitter and communicate foaming properties to the liquid by changing the surface tension. The investigation of the acids showed the *alpha acid* to have the composition $C_{15}H_{24}O_4$, and to contain a carboxyl group and a ketonic group. It is probable that this acid exists in the hops, condensed with a valeric acid residue. There is also present *humulone,* $C_{28}H_{32}O_5$, a lactone which is probably a product of the hydrolysis of the alpha acid. It is also probable that the alpha resin is a simple polymer of the alpha acid. The *beta acid,* $C_{25}H_{36}O_4$, is also called *lupulinic acid* and yields valeric acid on oxidation. The essential oil of hops contains *myrcene.*

Lupulite, a name formerly applied to the bitter substance of hops, is not a chemical individual. W. Wöllmer states that the bitter principles of hops, $C_{21}H_{30}O_4$ and $C_{26}H_{30}O_5$, are not true acids, but owe their acid character to their hydroxyl groups. He therefore prefers to call them *humulone* and *lupulone.* He split humulone into carbon dioxide, isopentane, and a body, $C_{16}H_{24}O_5$; while lupulone was broken into isopentane and a body, $C_{21}H_{34}O_4$. Both humulone and lupulone on boiling with alkali yield *humulinic acid,* $C_{15}H_{22}O_4$, and an unsaturated acid, $C_6H_{10}O_2$. (*Chem. Abstracts,* 1919, xiii, 495.) There is present also a peculiar tannin known as *humulo-tannic acid,* which is hydrolizable into glucose and a substance called *hop-red.* (See also *Lupulinum.*)

References to the literature of hops will be found in *Tr. Chem. Soc.,* 1913, ciii, p. 1267, Power and Tutin; in *Proc. Chem. Soc.,* 1913, xxix, p. 132, Chapman; in *Jour. of the Industry of Brewing,* 1913, xix, p. 261, Garrigues; in *Rep. Pharm.,* 1922, xxxii, p. 322, and in *J. Soc. Chem. Ind.,* 1920, xxxix, p. 498a.

Uses.—Hops is an aromatic bitter and hence may be useful in *atonic dyspepsia.* By many they are believed to have a sedative effect on the nervous system and are used in *hysteria, restlessness, insomnia,* and the like. Whether this latter action is due to anything more than an effect through the imagination is open to question.

An *infusion* prepared with half an ounce of hops and a pint of boiling water may be given in the dose of four fluidounces (120 cc.). The tincture was a British official preparation of hops, but the alcohol probably acts more decidedly upon the system than the hops. The fluidextract of hops of the N. F. is superior because of the relatively smaller amount of alcohol. A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with water, containing a trace of glycerin, previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and tumefactions.

Dose, thirty to ninety grains (2.0–5.8 Gm.).

Off. Prep.—Fluidextractum Humuli, *N. F.;* Tinctura Humuli, *N. F.*

HYDRANGEA. N. F.

HYDRANGEA Hydrang. [Seven-Barks]

"Hydrangea consists of the dried rhizome and roots of *Hydrangea arborescens* Linné (Fam. *Saxifragaceæ*). Hydrangea contains not more than 3 per cent. of foreign organic matter." *N. F.*

Wild Hydrangea, Seven Barks. Hortensia, *Fr.;* Hortensie, *G.*

This showy native shrub is closely related to the familiar cultivated hydrangea. It is found throughout the eastern part of the United States on rocky banks, along streams or rivers. It reaches a height of from five to ten feet and bears large clusters of white flowers in compound cymes; the marginal flowers being usually conspicuous and sterile and the central ones small and fertile. A peculiar characteristic is that the bark peels off in separate layers of different colors which has given rise to the popular name of "seven barks."

The commercial supplies of hydrangea are obtained chiefly from North Carolina, Virginia, Michigan and Illinois.

Description and Physical Properties.—"*Unground Hydrangea.*—Rhizome cylindrical, usually cut into pieces from 3 to 10 cm. long and from 3 to 20 mm. in diameter; externally light brown to yellowish brown with a pinkish tinge, longitudinally wrinkled, the upper portion marked by few elliptical lenticels and occasional prominent buds, short branches or stem scars; from the lower surface arise a few coarse fibrous roots; fracture tough, splintery, internally yellowish white or light brown, bark thin, easily separable from the distinctly radiate wood which surrounds a prominent whitish pith. Roots attaining a length of 25 cm. and a thickness of 2 mm., irregularly bent and branching, otherwise resembling the rhizome with the exception of the pith being absent. Inodorous; taste sweetish, becoming slightly acrid.

"*Structure.*—Rhizome: a few rows of grayish, tabular cork cells; a cortex made up chiefly of parenchyma containing starch, large cells containing raphides of calcium oxalate and small isolated groups of fibers and stone cells; a wood cylinder composed of slender wedges of tracheæ and tracheids separated by medullary rays 1 to 3 cells in width, the cells of the latter containing starch grains; pith of large polygonal cells with prominent simple pores.

"*Powdered Hydrangea.*—Light yellowish; irregular fragments consisting of strongly lignified tracheæ with reticulate thickenings, tracheids and medullary ray cells; strongly lignified stone cells and fibers from 0.030 to 0.200 mm. in length, the walls marked with simple or branching pores; raphides of calcium oxalate numerous from 0.050 to 0.135 in length; starch grains mostly single, ellipsoidal, up to 0.010 mm. in diameter, occasionally with a prominent central cleft." *N. F.*

Bondurant (*A. J. P.*, 1887, 122) isolated a characteristic glucoside, *hydrangin*, crystallizing in stellate clusters, melting at 235° C., and subliming without decomposition. It is decomposed by dilute acids into a resin-like body and glucose. Its aqueous solution fluoresces strongly on addition of an alkali, resembling æsculin, but distinctly different in several particulars. Bondurant also obtained a fixed oil and a volatile oil, the latter containing sulphur. Two resins seemed also to be present, together with saponin and sugar. He found no tannin, however. Y. Asahina has isolated two crystalline substances from the alcoholic extract of the flowers of *H. Hortensia*, the Chinese plant which is widely cultivated as an ornamental shrub in this country, *hydragenol* and *hydrangeaic acid*.

Uses.—Hydrangea is said to have been used by the Cherokee Indians. It was at one time used in medicine in the treatment of *stone* in the bladder and *cystitis* but has been largely abandoned. In overdose it is said to cause vertigo and oppression of the chest.

Dose, thirty grains (2 Gm.).

Off. Prep.—Fluidextractum Hydrangea, *N. F.;* Elixir Hydrangeæ et Lithii, *N. F.*

HYDRARGYRI CHLORIDUM CORROSIVUM. U. S. (Br.)

CORROSIVE MERCURIC CHLORIDE Hydrarg. Chlor. Corr. [Bichloride of Mercury, Corrosive Sublimate, Mercuric Chloride]

"Corrosive Mercuric Chloride contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.5 per cent. of $HgCl_2$." *U. S.* "Mercuric Chloride may be obtained as a sublimate by heating a mixture of mercuric sulphate, sodium chloride, and black oxide of manganese. It contains not less than 98.6 per cent. of pure mercuric chloride, $HgCl_2$." *Br.*

Hydrargyri Perchloridum, *Br.;* Perchloride of Mercury, Sublimatus Corrosivus, Chloruretum (Chloretum) Hydrargyricum, Hydrargyrum Sublimatum Corrosivum, Hydrargyri Bichloridum; Hydrargyrum Muriaticum Corrosivum, Sublimatus Corrosivus, Mercurius Sublimatus Corrosivus; Corrosive Chloride of Mercury, Sublimé Corrosif, Chlorure mercurique, *Fr.;* Bichlorure de Mercure, *Fr. Cod.;* Hydrargyrum Bichloratum, *P. G.;* Quecksilberchlorid, Aetzender Quecksilbersublimat, *G.;* Bicloruro di mercurio, *It.;* Cloruro mercurico, Soliman, *Sp.*

The names given in the two Pharmacopœias to this important chloride do not exactly correspond. It is called *Hydrargyri Chloridum Corrosivum* in the U. S. Pharmacopœia, and *Hydrargyri Perchloridum* in the British. We prefer the former, as indicating, beyond any possibility of mistake, the article intended, as well as its corrosive property. Perchloride and subchloride are hardly sufficiently distinctive, when a mistake may be so serious as that of confounding corrosive sublimate and calomel. Indeed, death has at least in one recorded instance occurred in consequence of this confusion of nomenclature, and our official guides should take especial care to guard against such mistakes. The British Pharmacopœia (1898) uses for the English names mercuric chloride for corrosive sublimate and mercurous chloride for calomel, but these names are not used in prescription writing.

Preparation.—Corrosive sublimate may be made by heating sulphuric acid and the metal together, in a chamber so arranged as to carry off the sulphurous oxide, to form mercuric sulphate; the dry salt obtained is then mixed with sodium chloride and a small quantity of manganese dioxide, and the mixture sublimed. This method, which was formerly official, may be found in the *U. S. D.*, 19th ed., p. 617. It is usually made on the large scale, by the direct combination of gaseous chlorine with mercury which is heated almost to the volatilizing point. It is also sometimes manufactured by dissolving mercuric oxide (red precipitate) in hydrochloric acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the chloride. This method may be used in emergencies for making small amounts.

Description and Physical Properties.—"Heavy, colorless, odorless, rhombic crystals, or crystalline masses, or a white powder. *Caution*

—*Corrosive Mercuric Chloride is extremely poisonous.* One Gm. of Corrosive Mercuric Chloride is soluble in 13.5 cc. of water, 3.8 cc. of alcohol, about 12 cc. of glycerin, and in 22 cc. of ether, at 25° C. One Gm. is soluble in 2.1 cc. of boiling water and in 1.6 cc. of boiling alcohol. The salt fuses to a colorless liquid at about 265° C. and at about 300° C. volatilizes as a dense, white vapor.

"An aqueous solution of Corrosive Mercuric Chloride (1 in 20) is acid to litmus paper, but becomes neutral upon the addition of sodium chloride. An aqueous solution of the salt (1 in 20) responds to the reactions for mercuric compounds, and for chlorides.

"When volatilized at about 300° C., Corrosive Mercuric Chloride leaves not more than 0.1 per cent. of residue. Not more than 0.5 per cent. of residue remains on dissolving finely powdered Corrosive Mercuric Chloride in ether or alcohol.

"**Assay.**—Dry about 0.5 Gm. of Corrosive Mercuric Chloride to constant weight over sulphuric acid, weigh accurately, and dissolve in 300 cc. of warm water to which 1 cc. of hydrochloric acid has been added. Pass hydrogen sulphide through the cold solution until saturated when the precipitate of mercuric sulphide readily subsides, leaving a clear supernatant liquid. Collect the precipitate on counterpoised filters or on a Gooch crucible, wash it well with cold distilled water, and finally with three portions of about 10 cc. each of alcohol. Then close the tip of the funnel with a cork stopper, add sufficient carbon tetrachloride to cover the precipitate, cover the funnel with a watch-glass, and allow it to stand for about half an hour. Then drain off the solvent, and wash the precipitate with further portions of carbon tetrachloride until, after evaporating about 1 cc. of the filtrate, no visible residue remains. Remove the adhering carbon tetrachloride by washing with several portions of 10 cc. each of alcohol, and, after drying in the air, transfer to an oven and dry to constant weight at about 110° C. The weight of mercuric sulphide obtained, when multiplied by 1.167, indicates its equivalent in $HgCl_2$. Each Gm. of Corrosive Mercuric Chloride, previously dried to constant weight, corresponds to not less than 0.8526 Gm. of mercuric sulphide. Corrosive Mercuric Chloride, previously dried to constant weight, may also be assayed by the electrolytic method.

"Preserve in well-closed containers." *U. S.*

"Heavy, colorless, crystalline masses, possessing a highly acrid, metallic taste. Soluble is 18 parts of *water,* and in 4 parts of *alcohol* (90 per cent.), or of *ether.* Yields the *reactions* characteristic of mercuric salts and of chlorides. When heated Mercuric Chloride sublimes without decomposition, leaving only a trace of fixed residue. Yields not less than 72.8 or more than 73.8 per cent. of metallic mercury, Hg, when tested by the following process:—Dissolve 0.5 gramme in 20 millilitres of *water* in a tared beaker-flask, add 10 millilitres of *hypophosphorous acid,* or sufficient to reduce the whole of the mercuric chloride present, and heat on a water-bath until the particles of mercury that separate collect at the bottom of the flask. Pour the contents of the flask on a tared filter-paper, wash both the flask and filter-paper successively with *water, alcohol* (90 per cent.), and *ether;* dry over *sulphuric acid,* and weigh the metallic precipitate." *Br.*

Ether is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution when agitated with it. According to Mialhe, ether will not dissolve it when accompanied by a considerable quantity of mercuric oxide and a chloride of an alkalifiable metal. Sulphuric, nitric, and hydrochloric acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapors, which condense on cool surfaces, in white, shining needles. It is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is mercuric hydroxide, which has the property of evolving oxygen and of being reduced to metallic globules when exposed to heat. This hydroxide is formed in the process for preparing *aqua phagedænica,* called also *yellow wash.* (See *Lotio Hydrargyri Flava.*) Corrosive sublimate forms, with ammonium chloride, and sodium chloride, compounds which are more soluble than the uncombined mercurial salt. The combination of corrosive sublimate with ammonium chloride was formerly called *sal alembroth,* or *salt of wisdom.*

Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime water, tartar emetic, silver nitrate, the lead acetates, the potassium and sodium sulphides, the soluble iodides, and all the sulphydrates. It is decomposed by many vegetable and some animal substances. According to A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horseradish, calumba, cinchona, gambir, rhubarb, senna, simaruba, and oak bark. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. Samuel Kennedy (*Ph. Rec.,* 1888, p. 201) proved conclusively that when corrosive sublimate was dissolved in compound syrup of sarsaparilla, as frequently prescribed, precipitation invariably occurred. He found that if sodium chloride in quantity equalling that of the mercurial used were added, precipitation was greatly retarded.

Uses.—Corrosive sublimate is a powerful mercurial and may be used for the various purposes for which the other preparations of this metal are employed. (See *Hydrargyrum.*) When administered in large doses it is prone to irritate the stomach and intestines and, therefore, such large quantities of mercury cannot be introduced into the system with this salt as with calomel. It is one of the best of all the preparations of mercury for hypodermic use in *syphilis*. From ten to twenty minims of an 0.5 per cent. solution in distilled water may be thrown deeply into the muscles preferably of the back. The pain of the injection may be obviated by the previous injection of procain. Most careful asepsis is necessary to avoid abscess formation.

It has been employed, especially by intravenous injection with asserted benefit in *septicemia*, especially following child-birth. Stowe (*Chicago Medical Recorder*, 1911, xxxiii, p. 461) injects one-fifth of a grain at a dose. Its value for this purpose is very questionable.

Externally employed, corrosive sublimate is stimulant, escharotic, and germicidal. The powdered chloride has been used as an escharotic, but is, in general, inferior to silver nitrate or potassium hydroxide. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of zinc sulphate, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals. This practice originated, we believe, with Perkins, of Philadelphia, and was highly recommended by Physick. Geo. B. Wood often employed it with success. A solution of corrosive sublimate in collodion (four parts to thirty) has been used as a caustic, for the destruction of *nævi materni*, and for other purposes. It can be very accurately applied, but its use requires care, as fatal poisoning has followed a single application of the alcoholic solution of corrosive sublimate to a moderate surface of *ringworm*. (*L. L.*, 1871, ii, 413.) It is applied by means of a camel's-hair pencil.

Corrosive sublimate is one of the most powerful of known chemical germicides. Solutions containing one part in twenty thousand are sufficient to destroy the vitality of most nonsporulating bacteria while one in one thousand will kill the most resistant sporulating organisms. According to Koch, one part in three hundred thousand absolutely prevents the multiplication of the *Bacillus anthracis*, while Behring (*D. M. W.*, 1887) finds that as little as one part in a million has a distinctly inhibiting effect. The practical utility of mercuric chloride as a disinfectant is, however, greatly limited by its chemical instability. It has a strong affinity for albumen, and, although the precipitate formed is redissolved in an excess of albumen, the disinfectant power of mercury is very much reduced. Moreover, it attacks most metals which are used in surgery and is therefore unsuitable for disinfecting instruments. Nevertheless, because of its convenience as well as its powerful action it is very widely employed as a germicide for surgical purposes.

The solution of one in one thousand may be used for washing the hands, disinfecting furniture, etc., and is even employed in the disinfecting of *wounds;* usually, however, a much weaker solution than that just mentioned is employed by the surgeon. It is rarely if ever justifiable to use upon a mucous surface or a wound a solution stronger than one in two thousand, and if the solution is to be used freely and continuously, as in washing out the vagina, etc., one in ten thousand is as strong as should be employed; indeed, the employment of a vaginal wash of this strength has been followed by violent poisoning. (See H. C. Wood, Jr., *Am. Med.*, Dec., 1902, and Bland, *A. J. M. S.*, 1920, lxxiv, 1227.) In a number of cases a solution of one part in fifteen hundred used locally by the surgeon has produced death, preceded by constitutional symptoms.

It is essential that the tablets be colored or in some way marked so that the attention may be drawn to their nature, and accidental poisoning prevented. Mercuric chloride tablets are now officially recognized. (See *Toxitabellæ Hydrargyri Chloridi Corrosivi.*)

Poisoning.—Because of the ease with which it is obtained corrosive sublimate is one of the most commonly used poisons for suicidal purposes, and the wide-spread employment of tablets of it as antiseptics has led to a number of accidental cases. The symptoms of poisoning by bichloride of mercury generally come on promptly with a metallic taste, burning pain in the gullet and epigastrium, followed by vomiting and purging. The vomitus is first mucous or bilious, but later becomes bloody; the stools also usually contain blood. In many cases there is a profound collapse, as shown by rapid feeble pulse, cold clammy skin, and muscular weakness, even comparatively early in the poisoning. The urine becomes scanty or may be entirely suppressed, albuminous, and sometimes hemorrhagic. If the patient survives for a few days salivation develops and ulcers appear around the mouth and throat. Death may occur within a few hours of the ingestion of the poison, but may be postponed for nearly a fortnight. In postmortem examination the whole alimentary canal is found the seat of a corrosive inflammation, there is violent nephritis and sometimes protoplasmic degenerations in the internal organs. It is not necessary for the poison to be swallowed in order to produce serious or even fatal results; H. C. Wood, Jr. (*American Medicine*, 1902, iv, p. 1006), has found references to more than 150 cases of poisoning from its use as intra-uterine douches of which a large number ended fatally, and Craig (*J. A. M. A.*, 1906, xlvii, p. 1484) has reported death from the application of an alcoholic solution to the back and arm.

Formerly, the prognosis of poisoning by mercuric chloride depended almost entirely upon the dose which had been ingested; there was no treatment known which had any influence upon the progress of the intoxication. Within recent years, however, through the investigations of MacNider (*J. Ex. M.*, 1918, xxvii, xxviii and *J. M. R.*, 1916, xxix, and 1919, xxxix), of Fantus (*J. Lab. and Clin. Med.*, 1916, i, p. 879), of Lambert and Patterson (*A. I. M.*, 1915, p. 65) and others, a very large proportion of cases can be saved even after the ingestion of doses far in excess of those ordinarily fatal.

The modern treatment divides itself into two stages:—efforts to prevent absorption of the poisoning and efforts to lessen the destructive action upon the kidneys after absorption.

There are two methods of preventing the absorption of the poison; one is the mechanical evacuation and the other its chemical precipitation. Both of these are important. The stomach may be evacuated either by the use of an emetic or by the stomach tube, whichever can be obtained most promptly. Vomiting alone, however, should not be relied upon; as soon as possible a stomach tube should be obtained and the stomach washed out repeatedly until the fluid recovered no longer responds to a test with a sulphide.

Formerly, the white of egg was universally recommended as chemical antidote to corrosive sublimate on the theory that it would form an insoluble albuminate of mercury. The albuminate of mercury, however, is not completely insoluble in acid menstruum and sufficient may be dissolved by the gastric juice to exercise a caustic action; moreover, after the albuminate of mercury passes from the stomach to the intestines the mercury is readily absorbed. The experiments of Fantus have demonstrated beyond all cavil that while the administration of egg albumen within two or three minutes after the ingestion of corrosive sublimate may lessen the severity of the gastric lesions it has very little influence upon the final outcome of the poisoning and if not administered immediately does not effect even the gastric lesions. In his experiments he found that the best results were achieved by combinations of sodium phosphite and sodium acetate or of sodium hypophosphite with hydrogen dioxide. Sodium phosphite is not an article commonly found in the pharmacies. Fantus has suggested that tablets containing 0.36 Gm. of sodium phosphite and 0.24 Gm. of sodium acetate might be stocked in pharmacies as mercurial antidote and Linhart (*J. Lab. Clin. Med.*, 1917) has described a process for manufacturing sodium phosphite. The hypophosphite mixture of Fantus contains 1 Gm. of sodium hypophosphite, and 5 cc. of the solution of hydrogen dioxide in 10 cc. of water. This should be given so that there is at least ten times as much of the hypophosphite as of corrosive sublimate. In 1912, Hayward and Allen (*J. A. M. A.*, lx, 1727) in pointing out the inefficiency of egg albumen suggested the use of calcium sulphide (formerly official as Calx Sulphurata) as a chemical antidote. They asserted that 1 Gm. of calcium sulphide is sufficient to completely reduce 2.3 Gm. of mercuric chloride but do not appear to have made any actual tests of its efficacy. Since that time it has been employed by a number of investigators with apparently good results. Wilms (*Lancet Clinic,* 1915, cxiv, 555) goes so far as to assert, on the basis of both experimental and clinical evidence, that even after the absorption of the mercury the intravenous injection of calcium sulphide is capable of preventing its destructive effects on the body tissues but this has been contradicted by Haskell and Courtney (*J. Lab. Clin. Med.*, 1918). Fantus has objected to the use of calcium sulphide because he has found that the antidote itself is toxic to rabbits but the amount that he administered was equivalent to 80 grains (5 Gm.) for an ordinary man, a dose far in excess of that which could conceivably ever be needed. Holm (*Journal of the Michigan State Med. Society,* July, 1917) recommends that one to five grains of calcium sulphide be administered every hour until the odor of hydrogen sulphide is perceptible upon the breath. Whichever antidote is chosen should be repeated every six hours for two days.

The most frequent fatal lesion produced by mercury is nephritis. The experiments of MacNider have shown, first, that there is in mercurial poisoning an acidosis (*i.e.*, a diminished alkalinity of the blood) and secondly, that the more alkaline is the blood the less injurious is mercuric chloride to the kidney. It would seem from these experiments that the most important therapeutic effort, aside from those directed to limit the absorption of the poison, should be to conserve the alkalinity of the blood. The method of treatment which was brought forward by Lambert and Patterson before the publication of MacNider's experiments and which has proven clinically very valuable, although based upon an entirely different theory, probably owes its beneficial effects largely to the alkali which is incidentally introduced. Weiss (*J. A. M. A.*, 1917, lxviii, 1618) recommends, for the purpose of alkalizing the system, the intravenous injection of *Fischer's solution*—which consists of sodium carbonate 10 Gm., sodium chloride 15 Gm., water to 1000 cc.—and in addition the drinking of large quantities of a solution of potassium bitartrate and sodium citrate flavored with lemon or orange juice; the citrates and acetates are oxidized in the system and eventually appear in the blood as carbonates. Whatever the form of alkali employed it is probably a matter of small moment whether it be introduced intravenously, by the mouth or, as suggested by Lambert and Patterson, by colonic irrigation. The important factor is that it should be given in sufficient quantity to render and to keep the urine alkaline. In addition to efforts at alkalizing the body, theory would suggest the introduction of large amounts of fluid, with the idea of diluting the poison in the blood, and there is much clinical evidence in favor of this view. (See Gatewood and Byfield, *A. I. M.*, 1923, xxxii, 456 and Haskell et al., *J. A. M. A.*, 1923, lxxxi, 448.) The use of sweat baths was formerly recommended apparently with the idea that the mercury can be eliminated through the skin. We know of no reason for believing in the usefulness of this measure.

Details of the treatment of corrosive sublimate poisoning as applied in the U. S. Navy may be found in the *A. J. P.*, 1921, xciii, p. 792.

Tests for Corrosive Sublimate.—On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations.

If the mixture suspected of containing corrosive sublimate be wholly inorganic the following tests may be used for its detection: A preliminary test for mercury may be made with copper foil and strong hydrochloric acid. (Reinsch's test.) If the foil be darkened or changed it may be dried, placed in a tube of hard glass and heated when mercury will distil and separate in the cooler portions of the tube where it may be recognized by an examination under the microscope which will reveal the characteristic globules of the element. Tests in an aqueous solution of the substance may also be applied with hydrogen sulphide solution, which precipitates black mercuric sulphide; with potassium iodide solution, which cautiously added in just the proper amount precipitates red mercuric iodide; with an alkaline carbonate or hydroxide, which will precipitate the yellow mercuric oxide; and with stannous chloride solution which will reduce mercuric salts to mercurous and will thus give a white precipitate of calomel. The chlorine may be recognized by the customary silver nitrate test.

If any organic matter be present most or all of the foregoing tests will fail. As the mercury compounds will probably be volatilized if ignition be resorted to, the destruction of the organic matter must be accomplished in the wet way by heating the substance with strong hydrochloric acid, and then cautiously adding powdered potassium chlorate in small portions, continuing the heating until the organic matter is completely destroyed and the dark color which the mixture originally assumed upon heating with the acid, has changed to a clear golden yellow. This solution may then be carefully heated to drive off the free chlorine and the tests as previously described may be applied.

Dose, of corrosive sublimate, from one-fortieth to one-eighth of a grain (0.0015–0.008 Gm.), preferably given after meals, in solution.

HYDRARGYRI CHLORIDUM MITE.
U. S. (Br.)

MILD MERCUROUS CHLORIDE Hydrarg. Chlor. Mit. [Calomel, Mercurous Chloride, Subchloride of Mercury]

"Mild mercurous chloride contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.6 per cent. of HgCl." *U. S.* "Mercurous Chloride, HgCl, is obtained as a sublimate by heating a mixture of mercurous sulphate and sodium chloride." *Br.*

Hydrargyri Subchloridum, *Br.;* Mercury Subchloride; Calomelas; Hydrargyri Chloratum; Precipitatum Album; Mercurius Dulce; Chloruretum Hydrargyrosum; Mild Chloride of Mercury; Chlorure Mercureux, Mercure Douce, Precipité Blanc, *Fr.;* Protochlorure de Mercure, *Fr. Cod.;* Hydrargyrum Chleratum, *P. G.;* Quecksilberchlorur, *G.;* Protocloruro di Mercurio, *It.;* Cloruro Mercurioso Sublimado, *Sp.*

Very properly, processes for this compound have been omitted from the Pharmacopœias, as it cannot be made by the pharmacist conveniently. For processes of the U. S. P., 1870, and of the Br. Pharm., 1885, with remarks, see *U. S. Dispensatory,* 19th edition, p. 623.

The original method of making calomel was practised at Apothecaries' Hall, London, by taking advantage of the following reaction:

$$HgSO_4 + 2NaCl + Hg = Na_2SO_4 + 2HgCl$$

To bring the calomel into a state of minute division the method of Joseph Jewell, of London, improved by Ossian Henry, is sometimes employed. It consists in causing the calomel in vapor to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury,* is free from all suspicion of containing corrosive sublimate, and is much finer than when obtained by levigation and elutriation. This kind of calomel is included in the French Codex under a distinct name. (*Mercure* (*Protochlorure de*) *par volatilization.*) For other methods at one time suggested see *U. S. D.*, 20th ed., p. 555.

When in mass, it is generally in the form of a white, fibrous, crystalline cake, the interior of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7.2. Patch found (*Proc. A. Ph. A.*, 1885, p. 477) the sp. gr. of calomel to vary from 6.94 to 7.93. It is official only in the powdered state. The powder has a light buff or ivory color, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of mercurous oxide, reducible by heat to the metallic state.

The preparation employed under the name of *lotio nigra,* or *black wash,* is used as a local application to syphilitic *ulcers,* etc. (See *Lotio Nigra,* Part III.)

Description and Physical Properties.—" A heavy white, impalpable powder, becoming yellowish-white when triturated with strong pressure, and showing only small, isolated crystals when viewed under a lens having a magnifying power of one hundred diameters. It is odorless, and is stable in the air. Mild Mercurous Chloride is insoluble in water, alcohol, ether, and in cold dilute acids. When heated to about 383° C., Mild Mercurous Chloride is volatilized without fusion or the evolution of brown vapors.

" The salt is blackened by contact with calcium hydroxide T.S., with a solution of an alkali hydroxide, or with ammonia T.S. When heated in a dry glass tube with an equal weight of dried sodium carbonate (free from chloride), Mild Mercurous Chloride yields a sublimate of metallic mercury. When the residue is dissolved in nitric acid and filtered, silver nitrate T.S. produces in the filtrate a white, curdy precipitate, insoluble in nitric acid.

" When volatilized at about 300° C., Mild Mercurous Chloride leaves not more than 0.1 per cent. of residue. Shake 2 Gm. of the salt with 20 cc. of ether for five minutes, filter, and allow the filtrate to evaporate spontaneously: the residue, dissolved in 10 cc. of distilled water and 2 drops of diluted nitric acid, shows no more *chloride* than corresponds to 0.1 cc. of fiftieth-normal hydrochloric acid (*mercuric chloride*). Heat 1 Gm. of the salt with sodium hydroxide T.S.: no ammonia is evolved (*ammoniated mercury*).

" **Assay.**—Dry about 0.7 Gm. of Mild Mercurous Chloride to constant weight over sulphuric acid, weigh accurately, mix well with 10 cc. of distilled water in a glass-stoppered flask, and add 50 cc. of tenth-normal iodine and 5 Gm. of potassium iodide dissolved in 10 cc. of distilled water. Stopper the flask, allow the mixture to stand with occasional agitation until complete solution has taken place, and then titrate the residual iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.02361 Gm. of HgCl. Mild Mercurous Chloride, previously dried to constant weight, may also be assayed by the electrolytic method.

" Preserve in well-closed containers, protected from light." *U. S.*

" A heavy dull white powder, sometimes rendered yellowish by prolonged trituration; nearly tasteless. Insoluble in *water,* in *alcohol* (90 per cent.), and in *ether;* soluble in a boiling mixture of *nitric acid* and *hydrochloric acid,* the solution, when diluted with *water,* yielding the *reactions* characteristic of mercuric salts. Volatilises when sufficiently heated, leaving not more than a trace of fixed residue. Warmed with *solution of sodium hydroxide* it becomes black, but does not evolve ammonia (absence of mercuric-ammonium chloride). When 1 gramme is well shaken with 10 millilitres of *water* and filtered, the filtrate is not darkened by *hydrogen sulphide* (absence of mercuric chloride)." *Br.*

Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, sulphydrates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.,* cvi, 500.)

Calomel should not be given at the same time with nitrohydrochloric acid, for fear of generating corrosive sublimate; death is reported to have followed such a combination. According to the experiments of Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, mercuric cyanide, and ammonium chloride are formed; in the latter, corrosive sublimate and mercuric cyanide only; hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by Mialhe and Prenleloup, and more recently it has been shown by E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate.

The alkali bromides produce appreciable amounts of mercuric salts when brought into contact with calomel in the presence of water and should never be given in combination.

Uses.—As an alterative calomel may be used for the general properties of the mercurials. (See under *Hydrargyrum.*) It it relatively non-irritant to mucous membranes and may be given in large doses so that it is possible to bring the system under the general influence of the mercury very rapidly. The use of calomel ointment instead of the blue ointment for inunction in *syphilis* has been suggested but Cole and Littman (*J. A. M. A.,* 1919, lxxiii) found the treatment of practically no value.

Aside from its alterative action, mercurous chloride is used as a cathartic, diuretic, and antiseptic. As a laxative it is slow but thorough in its action, affecting both upper and lower bowels. While the former belief that it was a stimulant to hepatic secretion has been shown to be incorrect, it in some way increases the bile in the intestinal tract, perhaps through an action on the bile passages or perhaps through its antiseptic effect preventing the decomposition of the natural bile. It is therefore preferred in cases where there is an absence of this secretion as shown by light-colored stools, and in *biliousness.* It is also a valuable agent to cleanse the intestines in *enteritis* both because of the thoroughness of its effect and of its antiseptic action. When used as a purgative better effects may be obtained with less discomfort by giving it in divided doses; thus a quarter of a grain may be given every half hour until three or four grains have been taken. It is usually advisable to follow it the next day with a saline for the reason that if it should fail to operate sufficient mercury may be absorbed to cause salivation.

The mode of action of calomel as a diuretic is not yet positively determined, but there is abundant evidence that it is one of the most powerful stimulants to the kidney which we possess. According to Fleckseder (*W. K. W.*, 1911, p. 1421), it is especially useful in the severe dropsies of heart disease after the failure of other drugs. An old combination with digitalis and squill, frequently but incorrectly spoken of as *Niemeyer's pill*, is widely employed for this purpose. (See *Pilulæ Digitalis Scillæ et Hydrargyri*, Part III.) To obtain its diuretic effect it is usually necessary to give it in large doses. Ordinarily from a quarter to half a grain may be given every two hours until beginning ptyalism, but in emergencies where an immediate effect is desired it may be well to give five grains (0.32 Gm.) at once, repeating every two hours until fifteen grains (0.9 Gm.) have been taken. Purgative action may be guarded against by the simultaneous exhibition of opium.

Although calomel has long been used both externally and internally for its disinfectant properties, the studies of Schamberg and Kolmer (*J. A. M. A.*, 1914, lxii, p. 1950 and 1915, lxiv, 618) indicate that its germicidal power has been underestimated. According to these investigators, weight for weight it is equal to the corrosive sublimate. Externally it is used for a dusting powder in various infections of the eye, and in *venereal ulcers* and in the form of an ointment in various ulcerated conditions of the nasal or other mucous membranes. Internally it is used for its antiseptic action in various types of *enteritis* or *dysentery*.

Some commercial cosmetic preparations contain calomel in suspension, and it is has always been found difficult or impossible to duplicate these smooth suspensions with commercial calomel, which first forms a curd and then rapidly settles out. F. W. Nitardy (*J. A. Ph. A.*, 1914, p. 965) found it possible to communicate the desired suspending qualities to ordinary calomel by first shaking with a solution containing 5 per cent. by volume of mucilage of acacia, then allowing the calomel to settle out, decanting and discarding the supernatant liquid and replacing it with distilled water. By repeating this operation several times the acacia is all removed but the calomel retains its marked suspending quality.

The *dose* of calomel as an alterative is from one-sixth to one-third of a grain (0.01–0.02 Gm.); as a cathartic, from two to five grains (0.12–0.3 Gm.).

HYDRARGYRI IODIDUM FLAVUM. U. S.

YELLOW MERCUROUS IODIDE Hydrarg. Iod. Flav. [Mercurous Iodide]

"Yellow Mercurous Iodide contains, when dried to constant weight over sulphuric acid, not less than 99 per cent. of HgI." *U. S.*

Hydrargyri Iodidum Viride, *U. S. P.* 1880; Green Iodide of Mercury, Hydrargyri Iodidum, *U. S. P.* 1850; Iodide of Mercury, Yellow Iodide of Mercury; Protiodide of Mercury; Hydrargyrum Iodatum Flavum, Hydrargyri Protoioduretum, Ioduretum Hydrargyrosum; Iodurum Mercuriosum; Protiodure de Mercure, *Fr. Cod.;* Iodure mercureux, *Fr.;* Gelbes Jodquecksilber, *G.*; Protojoduro di mercurio, *It.;* Yoduro mercurioso, Protoyoduro de Mercurio, *Sp.*

The U. S. gives no process for making yellow mercurous iodide. The method of the U. S. P. VIII will be found in the U. S. Dispensatory, 20th ed., p. 558. It was essentially the process recommended by Edward Soetje (*Proc. A. Ph. A.*, 1888, p. 167), being a double decomposition between mercurous nitrate and potassium iodide in solution, *yellow* mercurous iodide and potassium nitrate being formed. From experiments by H. C. Wood, it appears that the *green* iodide is a mixture of yellow iodide and metallic mercury. By continuing the trituration, the powders become more and more yellow, and at length have only a tinge of green. He infers that pure mercurous iodide is yellow, and that the green color is owing to an admixture of the blue of the mercury with the yellow of the mercurous iodide. Flückiger (*Pharmaceutische Chemie,* 2d ed., 1888) agrees with this view, and says that by slow sublimation, at a very gentle heat, the true mercurous iodide can be obtained in small transparent yellow crystals of the quadratic system which are related to the forms of calomel. (See *J. P. C.*, 1894, 67.)

Description and Physical Properties.—"A bright yellow, amorphous powder, without odor or taste. By exposure to light it becomes greenish in proportion as it undergoes decomposition into metallic mercury and mercuric iodide. Yellow Mercurous Iodide is practically insoluble in water, and is insoluble in alcohol and in ether.

"When slowly and moderately heated, Yellow Mercurous Iodide assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is volatilized. When heated in a dry glass tube with an equal weight of dried sodium carbonate, Yellow Mercurous Iodide yields a sublimate of metallic mercury. When Yellow Mercurous Iodide is heated with surphuric acid and a little manganese dioxide, the vapor of iodine is evolved.

"When volatilized at about 300° C., Yellow Mercurous Iodide leaves not more than 0.2 per cent. of residue. Place 0.5 Gm. of Yellow Mercurous Iodide in a 10 cc. glass-stoppered cylinder, add 10 cc. of alcohol, shake by inverting the cylinder ten times, allow to stand protected from light for two minutes and shake again by inverting the cylinder ten times. Filter at once, refiltering if necessary until the filtrate is clear, and to 5 cc. of the filtrate add an equal volume of hydrogen sulphide T.S. The color produced is not darker than that produced by 5 cc. of hydrogen sulphide T.S. in a mixture of 1 cc. of mercuric chloride solution (made by dissolving 0.5 Gm. of mercuric chloride in 1000 cc. of distilled water) and 4 cc. of alcohol (*mercuric iodide*).

"**Assay.**—Dry about 1 Gm. of Yellow Mercurous Iodide to constant weight over sulphuric acid, weigh accurately, transfer to a glass-stoppered flask, add 50 cc. of tenth-normal iodine and 5 Gm. of potassium iodide dissolved in 10 cc. of distilled water. Stopper the flask, and allow the mixture to stand with occasional agitation until complete solution has taken place, and then filtrate the residual iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.03275 Gm. of HgI. Yellow Mercurous Iodide, previously dried to constant weight, may also be assayed by the electrolytic method.

"Preserve in well-closed containers protected from light." *U. S.*

Its sp. gr. is 7.75. If quickly and cautiously heated, it sublimes in red crystals, which afterwards becomes yellow. "Gradually heated in a test-tube, it yields a yellow sublimate, which, upon friction, or after cooling, becomes red, while globules of metallic mercury are left in the bottom of the tube." *Br.* 1867.

Uses.—Mercurous iodide is used in advanced *syphilis.* The dose is one-fifth of a grain (0.012 Gm.), gradually increased to two grains (0.13 Gm.). It should never be given at the same time with potassium iodide, which converts it into mercuric iodide and metallic mercury.

Dose, one-fifth of a grain (0.012 Gm.).

HYDRARGYRI IODIDUM RUBRUM.
U. S., Br.

RED MERCURIC IODIDE Hydrarg. Iod. Rub.
[Mercuric Iodide]

"Red Mercuric Iodide contains, when dried to constant weight over sulphuric acid, not less than 99 per cent. of HgI_2." *U. S.* "Red Mercuric Iodide, HgI_2, is obtained by the interaction of aqueous solutions of mercuric chloride and potassium iodide." *Br.*

Biniodide of Mercury; Red Iodide of Mercury; Mercurous Iodatus Ruber, Deutoioduretum Hydrargyri, Hydrargyrum Iodatum Rubrum, Ioduretum Hydrargyricum; Deutoiodide of Mercury; Iodure mercurique, *Fr.* Deuto-iodure Bi-iodure de Mercure, *Fr. Cod.;* Hydrargyrum Bijodatum, *P. G.* Quecksilberjodid, Rothes Jodquecksilber, *G.;* Bijoduro di mercurio *It.;* Yoduro mercurico, Biyoduro de Mercurio. *Sp.*

No process for preparing this salt is given in the U. S., nor British Pharmacopœias. The U. S. P. VIII process will be found in *U. S. D.,* 19th ed., p. 629.

This process involved a double decomposition between corrosive sublimate and potassium iodide, resulting in the formation of potassium chloride which remains in solution, and mercuric iodide which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either.

As obtained by this process it is in splendid crimson acicular crystals. When heated the mass becomes yellow at about 150° C., returning to red on cooling. Mercuric iodide is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. Ch. Ph.,* cix, 371.) It forms definite compounds with the iodides of the alkali metals. The compound formed with potassium iodide has been used as a medicine. (See *Mercury and Potassium Iodide,* Part II.)

Description and Physical Properties.—"A scarlet-red amorphous powder without odor. It is stable in the air. *Caution—Red Mercuric Iodide is extremely poisonous.* Red Mercuric Iodide is practically insoluble in water. One Gm. is soluble in 115 cc. of alcohol, 910 cc. of chloroform, and in 120 cc. of ether, at 25° C. One Gm. is soluble in 20 cc. of boiling alcohol. It is dissolved by solutions of the soluble iodides, mercuric chloride, sodium thiosulphate, and by hot solutions of the alkali chlorides. When heated to about 150° C. Red Mercuric Iodide become yellow, but again assumes a red color on cooling. At about 250° C. it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass. At about 350° C. it is volatilized.

"Boil about 0.1 Gm. of the salt with 2 cc. of sodium hydroxide T.S., filter, and strongly acidify the filtrate with nitric acid; the liquid becomes yellow from the liberation of iodine, which produces a blue color upon the addition of a few drops of starch T.S. Heat the salt with potassium hydroxide T.S., and add a little lactose; metallic mercury is precipitated.

"When volatilized at about 300° C., Red Mercuric Iodide leaves not more than 0.2 per cent. of residue. Agitate thoroughly about 0.5 Gm. of Red Mercuric Iodide with 10 cc. of distilled water, and filter; the filtrate does not become more than slightly colored upon the addition of hydrogen sulphide T.S. (*soluble mercury salts*). Not more than 0.004 Gm. of insoluble residue remains on dissolving 2 Gm. of Red Mercuric Iodide in 100 cc. of distilled water containing 2 Gm. of potassium iodide.

"**Assay.**—Dry Red Mercuric Iodide over sulphuric acid to constant weight, and assay by the electrolytic method.

"Preserve in well-closed containers, protected from light." *U. S.*

"A crystalline powder of a vermilion color, becoming yellow when heated to about 150° C. Almost insoluble in *water,* sparingly soluble in *alcohol* (90 per cent.), freely and entirely soluble in *ether* (absence of mercurous iodide), and in *solution of potassium iodide.* Yields the *reactions* characteristic of mercuric salts and of iodides. Volatilises at a temperature under redness, leaving not more than a trace of fixed residue. When 0.5 gramme is well shaken with 10 millilitres of *water* and filtered, the filtrate is not colored more than slightly brown by *hydrogen sulphide* (limit of mercuric chloride), and does not become more than opalescent on the addition of *solution of silver nitrate* (limit of chlorides)." *Br.*

Uses.—Mercuric iodide resembles corrosive sublimate in its activities and therapeutic uses. Like the chloride it is an intense local irritant and is capable of giving rise to violent gastroenteritis. It is also an active germicide, probably equal to the bichloride in power, although its sparing solubility has to a large extent prevented its practical employment. The double iodide of potassium and mercury has, however, been recommended as a practical disinfectant; Macfarlan (*A. J. M. S.*, 1920, clix) asserts that it is superior to the bichloride especially because of its lesser irritant and toxic properties. McKenna and Fisher (*Surg. Gyn. and Obstet.*, 1920, xxx, 370) highly recommend a one per cent. solution in acetone for the disinfection of the skin preceding operations. (See also *Mercury and Potassium Iodide,* Part II.) As an internal remedy mercuric iodide is employed especially in old obstinate cases of *syphilis,* and those attended with rheumatoid pains, or *diseases of the bones.*

Cazenave considers mercuric iodide to be the best topical application in *lupus.* He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation, which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly and on a level with the surrounding skin. A solution of mercuric iodide in olive oil (1 in 5000), which is to be prescribed as an external application, has been prepared by Delacour. (See *J. P. C.*, 1903, 603; 1904, No. 2.)

Dose, one-twentieth to one-twelfth of a grain (0.003–0.005 Gm.).

Off. Prep.—Liquor Arseni et Hydrargyri Iodidi, *U. S.* (*Br.*); Unguentum Hydrargyri Iodidi Rubri, *Br.*

HYDRARGYRI OXIDUM FLAVUM.
U. S., Br.

YELLOW MERCURIC OXIDE **Hydrarg. Oxid. Flav.**

"Yellow Mercuric Iodide, when dried to constant weight at 150° C., contains not less than 99.5 per cent. of HgO." *U. S.* "Yellow Mercuric Oxide may be obtained by the interaction of aqueous solutions of mercuric chloride and sodium hydroxide. It contains not less than 99.3 per cent. of pure mercuric oxide, HgO." *Br.*

Yellow Oxide of Mercury; Yellow Precipitate; Hydragyr Oxidatum Præcipitatum; Precipitated Oxide of Mercury; Mercuric Oxide; Oxydatum Hydrargyricum Flavum; Oxyde of Mercurique par Precipitation, *Fr.;* Oxide de Mercure Jaune, *Fr. Cod.;* Hydrargyrum oxydatum via humida paratum, *P. G.;* Präcipitirtes (Gelbes) Quecksilberoxyd, *G.;* Ossido mercurico giallo, *It.;* Oxido mercurico amarillo, *Sp.*

No process is given in the U. S. P. X or British Pharm. (1914) for this salt. The U. S. P. VIII process, which may be found in the *U. S. D.*, 20th ed., p. 561, depended on the decomposition of mercuric chloride in solution by sodium hydroxide.

Yellow Mercuric Oxide is a completely amorphous powder, exhibiting no evidence of crystalline particles even under the microscope. It differs from the red oxide only by being amorphous and in a much more minute state of division, the red oxide by trituration acquiring an orange and finally a yellow color. In consequence of its different state of aggregation, it is much more quickly acted on by reagents than is the red oxide. Thus, oxalic acid combines with the yellow oxide at lower temperature, producing the white oxalate, more than it does with the red. The yellow oxide, in contact with chlorine, gives up oxygen to that element, forming hypochlorous acid and corrosive sublimate. The red oxide exercises scarcely any influence on the gas at common temperatures.

Description and Physical Properties.—"A light orange-yellow, odorless, amorphous, heavy, impalpable powder. It is stable in the air, but turns darker on exposure to light. Yellow Mercuric Oxide is practically insoluble in water, and insoluble in alcohol. It is readily dissolved by diluted hydrochloric or nitric acid, forming colorless solutions.

"When moderately heated, Yellow Mercuric Oxide assumes a red color. At about 600° C. it is completely decomposed into oxygen and metallic mercury, and is volatilized.

"When volatilized at about 300° C., Yellow Mercuric Oxide leaves not more than 0.2 per cent. of residue. When moistened with hot, distilled water, Yellow Mercuric Oxide is not alkaline to litmus paper. A solution of 0.5 Gm. of Yellow Mercuric Oxide in 25 cc. of either diluted hydrochloric or diluted nitric acid is not more than slightly turbid. Heat 0.5 Gm. of Yellow Mercuric Oxide for two hours in a test tube, on a water bath, with a solution of 1 Gm. of oxalic acid in 10 cc. of distilled water and 1 cc. of ammonia T.S., replacing from time to time the water lost by evaporation; it is converted into white or yellowish-white mercuric oxalate (*distinction from red mercuric oxide*).

"**Assay.**—Dry about 0.5 Gm. of Yellow Mercuric Oxide to constant weight at 150° C., weigh accurately, and dissolve it in a mixture of 10 cc. of distilled water and 5 cc. of nitric acid, and further dilute the solution with 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01083 Gm. of HgO. Yellow Mercuric Oxide, previously dried to constant weight, may also be assayed by the electrolytic method.

" Preserve in well-closed containers, protected from light." *U. S.*

"A yellow powder; insoluble in *water;* readily soluble in *hydrochloric acid,* the solution yielding the *reactions* characteristic of mercuric salts. When 1 gramme is shaken with 5 millilitres of *water* for five minutes, the mixture is neutral to *litmus.* When gently heated it assumes a red color. The solution obtained by dissolving 0.5 gramme in 2 millilitres of *nitric acid* and diluting with 20 millilitres of *water* requires not less than 45.8 millilitres of *N/10 solution of ammonium thiocyanate* to produce a permanent pink coloration, *solution of ferric sulphate* being used as indicator. Heated to incipient redness it is resolved into oxygen and the vapor of mercury, leaving not more than 0.5 per cent. of fixed residue." *Br.*

I. Comere explains in a paper in *Répert. de Pharm.,* 1881, 199, the various conditions and modifications in the process necessary to make the oxide vary in color. (*N. R.,* 1882, 149.)

Uses.—The attention which has been paid to the yellow oxide is owing to its peculiar applicability to the local treatment of diseases of the eye, in consequence of its amorphous character. At present the yellow oxide is very largely used by oculists throughout the world in *conjunctivitis, hordeolum,* and other inflammations of the eye. It is generally employed in an ointment of about one-half to one per cent. strength. The red oxide, however carefully it may be triturated, even though in a perfectly impalpable state, still shows under the microscope crystalline particles, which in contact with the conjunctiva cause more or less irritation; it can, therefore, be readily understood that, in the ordinary mode of preparing it for use as an ointment, it may sometimes be productive of serious annoyance. From this objection the yellow oxide is exempt. The yellow oxide is also used largely in various *skin diseases,* notably *eczema* of the external auditory canal.

Off. Prep.—Unguentum Hydrargyri Oxidi Flavi, *U. S., Br.;* Oleatum Hydrargyri, *U. S.*

HYDRARGYRI OXIDUM RUBRUM. N. F., Br.

RED MERCURIC OXIDE Hydrarg. Oxid. Rub. [Red Precipitate]

" Red Mercuric Oxide contains, when dried to constant weight at 150° C., not less than 99.5 per cent. of HgO (216.60)." *N. F.*

" Red Mercuric Oxide may be obtained by heating mercurous nitrate until acid vapors cease to be evolved. Contains not less than 99.3 per cent. of pure mercuric oxide, HgO." *Br.*

Peroxide of Mercury, Red Oxide of Mercury, Red Precipitate; Mercurius Corrosivus Ruber vel Præcipitatus, Oxydum Hydrargyricum; Oxyde de Mercure Rogue, *Fr. Cod.;* Deutoxyde ou Péroxyde de Mercure, Précipité rouge, Poudre de Jean de Vigo, *Fr.;* Hydrargyrum Oxydatum, *P. G.;* Quecksilberoxyd, Rother Praecipitat, Quecksilber Præcipitat, Rothes Quecksilberoxyd, *G.;* Ossido mercurico rosso, *It.;* Oxido mercurico rojo, *Sp.*

This preparation has been dropped from the U. S. P., but is still retained by the N. F. and Br. The present Br. Pharm. gives no process, that of the 1885 edition was as follows:

" Take of Mercury, by weight, *eight ounces* [avoirdupois]; Nitric Acid *four fluidounces and a half* [Imperial measure]; Water *two fluidounces* [Imp. meas.]. Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together. Heat the mixture in a porcelain dish, with repeated stirring, until acid vapors cease to be evolved." *Br.* 1885.

For other methods which have been suggested see *U. S. D.,* 20th ed., p. 562.

The preparation is still frequently called by its older name, *red precipitate.* The name of *red mercuric oxide* is appropriate and more definite.

For a process for *Hydrargyrum præcipitatum per se, Precipitate per se,* or *calcined mercury,* all practically identical with red mercuric oxide, see *U. S. D.,* 17th ed., 704.

Description and Physical Properties.—" Red Mercuric Oxide occurs as heavy, orange-red, crystalline scales, or as a crystalline powder, acquiring a yellow color when finely divided; odorless and having a somewhat metallic taste, permanent in the air. Red Mercuric Oxide is almost insoluble in water; insoluble in alcohol; readily dissolved by diluted nitric acid, or by hydrochloric acid.

" When heated to about 400° C., Red Mercuric Oxide becomes dark violet or almost black, but assumes its original color on cooling. A solution of 0.5 Gm. of Red Mercuric Oxide in 25 cc. of either hydrochloric or nitric acid is not more than slightly turbid.

" Heat 0.5 Gm. of Red Mercuric Oxide for two hours, in a test tube on a water-bath, with a solution of 1 Gm. of oxalic acid in 10 cc. of distilled water and 1 cc. of ammonia water, replacing, from time to time, the water lost by evaporation; it will not change color within two hours (distinction from yellow mercuric oxide). At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized without leaving more than 0.2 per cent. of residue. Mix 1 Gm. of Red Mercuric Oxide with 5 cc. of distilled water, add 2 cc. of sulphuric acid, cool the mixture and carefully pour upon it 2 cc. of ferrous sulphate T.S.; no brown zone develops at the line of contact (*nitrate*).

"**Assay.**—Dissolve about 0.5 Gm. of Red Mercuric Oxide, previously dried to constant weight at 150° C. and accurately weighed, in 10 cc. of distilled water and 5 cc. of nitric acid, and further dilute the solution with 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent yellowish red color. Each cc. of tenth-normal potassium thiocyanate used corresponds to 0.01083 Gm. of HgO. Each gram of Red Mercuric Oxide, previously dried to constant weight, corresponds to not less than 91.9 cc. of tenth-normal potassium thiocyanate. Red Mercuric Oxide, previously dried to constant weight, may also be assayed by the electrolytic method (see U. S. P. X).

"Preserve it in well-closed containers, protected from light." *N. F.*

"Orange-red powder, or crystalline scales. Insoluble in *water;* soluble in *hydrochloric acid,* the solution yielding the *reactions* characteristic of mercuric salts. Gently heated it becomes dark violet, but resumes its orange-red color on cooling. Heated in a dry test-tube it does not evolve orange fumes (absence of nitrates). Responds to the quantitative test described under 'Hydrargyri Oxidum Flavum.' Heated to incipient redness it is resolved into oxygen and the vapour of mercury, leaving not more than 0.3 per cent. of fixed residue." *Br.*

Uses.—This preparation is too harsh and irregular in its operation for internal use and for external application is generally inferior to the yellow oxide. It is occasionally employed as a stimulating antiseptic, the powder being sprinkled on the surface of *chancres,* and *indolent, flabby,* or *fungous ulcers.* The powder should be finely levigated.

Hydrargyri Oxidum Nigrum, U. S. 1850. *Black Mercurous Oxide.*—This preparation has been dropped from both Pharmacopœias, and is now very rarely used. For a full account of its preparation, uses, and properties, see *U. S. D.,* 14th ed., 1256.

Off. Prep.—Unguentum Hydrargyri Oxidi Rubri, *N. F., Br.*

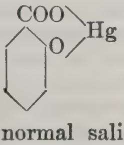
HYDRARGYRI SALICYLAS. U. S.

MERCURIC SALICYLATE Hydrarg Salicyl. [Mercuric Salicylate]

"Mercuric Salicylate is a compound of mercury and salicylic acid containing not less than 54 per cent. nor more than 59.5 per cent. of Hg." *U. S.*

Salicylas Hydrargyri; Salicylated Mercury; Hydrargyrum Salicylicum, *P. G.;* Salicilato Mercurico, *It.*

Mercuric salicylate is a compound of more or less varying chemical composition, having the approximate formula:



It is neither a normal salicylate nor a true subsalicylate as will be seen by the above formula which shows the mercury replacing both the phenolic and carboxylic hydrogen.

It is usually prepared by effecting a combination between freshly precipitated yellow mercuric oxide and salicylic acid in the presence of moisture and with gentle heating.

It is readily dissolved by solutions of alkalies which form double salts with it and from which solutions it is reprecipitated upon the addition of acids. It is decomposed by strong mineral acids.

Description and Physical Properties.—"An odorless, white, slightly yellowish or slightly pinkish powder. Mercuric Salicylate is practically insoluble in water and in alcohol. It is dissolved by solution of the fixed alkalies or their carbonates and by warm solutions of the alkali halides, with the formation of double salts.

"Heat 1 Gm. of Mercuric Salicylate with 10 cc. of hydrochloric acid; a solution is obtained from which salicylic acid separates on cooling. A piece of copper foil added to a portion of the filtered solution, nearly neutralized with ammonia T.S., immediately becomes coated with metallic mercury. To a mixture of 1 Gm. of Mercuric Salicylate with 10 cc. of distilled water add a few drops of ferric chloride T.S.; a violet color is produced.

"When volatilized at about 300° C., Mercuric Salicylate leaves not more than 0.2 per cent. of residue. Mercuric Salicylate does not redden moistened blue litmus paper (*free salicylic acid*). No dark color results at once on shaking about 0.1 Gm. of Mercuric Salicylate with 5 cc. of hydrogen sulphide T.S. (*foreign mercury compounds*). About 0.2 Gm. of Mercuric Salicylate dissolves completely in 4 cc. of normal sodium hydroxide.

"**Assay.**—Digest about 0.5 Gm. of Mercuric Salicylate, accurately weighed, in a mixture of 15 cc. of sulphuric acid and 10 cc. of nitric acid contained in a long neck flask in which a small funnel is inserted. Heat it upon a sand bath until the mixture is nearly colorless, then add another 10 cc. of nitric acid, and heat until the mixture is decolorized. Cool the solution, dilute it with 150 cc. of distilled water, add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate until a permanent yellowish-red color is produced. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg. Mercuric Salicylate may also be assayed by the electrolytic method.

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—Mercuric Salicylate is used chiefly in the treatment of *syphilis,* especially by intramuscular injection. The advantages claimed for it are that it is locally non-irritant and that it does not salivate. The first of these is due to its insolubility and the second is an evidence of its slow absorption. Nelson and Anderson (*J. A. M. A.,* 1915, lxv, 1905) reach the conclusion that, although there may be a subsidence of the objective manifestations of *syphilis* under the use of mercuric salicylate, the drug does not exercise a real curative effect. Hill (*J. A. M. A.*, 1923, lxxx, 1365), from experimental studies on rabbits, also reached the conclusion that it is of little value in syphilis. Mercuric salicylate is also used locally for its germicidal effect either as a dusting powder in the strengths of ten per cent., or as an injection in *gonorrhea,* one part of the drug being suspended in 300 of mucilage. It is also said to be a useful local application in *alopecia* of syphilitic origin.

For intramuscular injection a ten per cent. suspension in sterile liquid petrolatum may be employed. Of this ten minims (0.6 cc.) may be injected deeply into the muscles of the back or buttocks, under strict asepsis, two or three times a week. It has also been used by mixing with an equal part of potassium carbonate and dissolving in distilled water.

Dose, by mouth, one-twelfth to one-third grain (0.005–0.021 Gm.).

HYDRARGYRUM. U. S., Br.

MERCURY Hydrarg. [Quicksilver]

"Mercury contains not less than 99.5 per cent. of Hg." *U. S.* "Mercury is a liquid metal which may be obtained from native mercuric sulphide." *Br.*

Hydrargyrum Vivum, Mercurius Vivus, Argentum Vivum Hydrargyrum Depuratum, Mercure Purifié, *Fr. Cod.;* Vif Argent, *Fr.;* Hydrargyrum, *P. G.;* Quecksilber, *G.;* Mercurio, *It., Sp.*

Mercury is found pure, forming an amalgam with silver, in the form of chloride (native calomel), but most abundantly as the sulphide or native cinnabar. Mines of this metal are found at Almaden in Spain, at Idria in Carniola, in the former duchy of Deux-Ponts, in Belluno, a province of Venetia, in Corsica, in the Philippine Islands and China, near Huancavelica in Peru, near Azogue in Colombia, at Durango in Mexico, at Yulgilbar, New South Wales, in various localities in Santa Clara County, California, and in Brewster and other counties in Texas. The most ancient mine is that of Almaden in Spain, which was worked before the Christian era. This mine, and the mines of California, are the most productive at the present day, the Spanish mine yielding about three and a quarter millions of pounds, and the California mines about two-thirds of this amount annually. The ore in all the mines mentioned is *cinnabar.* The cinnabar from old Almaden is of a dull-red color in mass, of a dull brick-red color when in fine powder, and of the sp. gr. 3.6. That from New Almaden is of a bright-red color, slightly inclining to purple, not so hard as the Spanish ore, of a brilliant vermilion color in powder, and of the sp. gr. 4.4. The California cinnabar is richer in mercury, because purer, than the Spanish, the former yielding about 70 and the latter about 38 per cent. of mercury, according to the analysis of Adam Bealey. The California mine has been long known to the Indians, but its commercial value was first made known about 1843, by a Mexican, named Castillero, who became its first owner. At present it is in the hands of Americans. Ruschenberger has detected selenium in California cinnabar.

Mercury is obtained from cinnabar by two principal processes. According to one process, the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form calcium sulphide and sulphate, while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace beneath. In the upper and lateral part of the furnace, holes are made, communicating with several rows of *aludels,* formed of adapters passing into one another, which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay, and formed into small masses, which are placed on the floor of the furnace. Heat being applied, the sulphur burns, and the volatilized mercury passes through the aludels to be condensed in the chamber.

Mercury, as found in commerce, is contained in cylindrical wrought iron bottles, called flasks, each containing 75 pounds. The world's production at present is about 9,500,000 pounds. The chief uses of the metal are in mining silver and gold, in preparing vermilion, in making thermometers and barometers, in silvering looking glasses, and in forming various pharmaceutical compounds.

Description and Physical Properties.—"A shining, silver white metal, liquid at ordinary temperatures and easily divisible into spherical globules. When cooled to about –40° C., it forms a ductile, malleable mass. Specific gravity: about 13.5 at 25° C. Mercury is insoluble in the ordinary solvents, in concentrated hydrochloric acid, and at ordinary temperatures, in sulphuric acid, but it dissolves in the latter when boiled with it. It is readily and completely dissolved by nitric acid. Mercury boils at about 358° C.

"When volatilized at about 300° C., Mercury yields not more than 0.02 per cent. of residue. When globules of Mercury are dropped upon white paper, they roll about freely, retaining their globular form and leaving no streaks or traces. Mercury should present a bright surface, even after agitation in contact with air.

"**Assay.**—Dissolve about 0.4 Gm. of Mercury, accurately weighed, in a mixture of 10 cc. of distilled water and 10 cc. of nitric acid, warm the solution gently until red fumes cease to be evolved and the solution is colorless, and add 150 cc. of distilled water. Then add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate until a permanent reddish color is produced. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg. Mercury may also be assayed by the electrolytic method.

"Preserve in strong, well-closed containers." *U. S.*

"A silver-white, heavy liquid with a metallic lustre; easily devisible into globules. Readily volatilises when heated, leaving no appreciable fixed residue (absence of metallic and other impurities)." *Br.*

When perfectly pure it undergoes no alteration by the action of the air or water, but in its ordinary state suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and is converted into mercuric oxide; but at the temperature of ebullition it parts with the oxygen with which it had combined, and is reduced again to the metallic state. It boils at 358° C., yielding a colorless vapor, and congeals at –39.4° C., forming a malleable solid of tin-white color. It is a good conductor of heat, and its specific heat is small. It is not attacked by hydrochloric acid, nor by cold sulphuric acid; but boiling sulphuric acid or cold nitric acid dissolves it, producing mercurous sulphate and mercurous nitrate, respectively, with the liberation, in the former case, of sulphurous acid; in the latter, of nitrogen dioxide. Its combinations are numerous, and many of them constitute important medicines. It forms two series of compounds, the *mercurous* compounds containing the atom Hg^{I}, and the *mercuric* compounds containing the atom Hg^{II}.

Mercury, as it occurs in commerce, is in general sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, as lead, tin, zinc, and bismuth. Brande informs us that in examining large quantities of this metal in the London market he found it in only one instance intentionally adulterated. When impure, the metal has a dull appearance, leaves a trace on white paper, is deficient in due fluidity and mobility, as shown by its not forming perfect globules, is not totally dissipated by heat, and when shaken in a glass bottle coats its sides with a pellicle, or if very impure, deposits a black powder. If agitated with strong sulphuric acid, the adulterating metals become oxidized and dissolved, and thus the mercury may to a limited extent be purified. Mercury may be purified by digesting it with a small portion of weak nitric acid, or with a solution of mercuric chloride, whereby the ordinary contaminating metals will be removed. It may also be purified by distillation. For further details regarding the purification of mercury, see *U. S. D.*, 19th edition, p. 635.

Mercury is detected with great delicacy by Smithson's process, which consists in the use of a plate of tin, lined with one of gold, in the form of a spiral. When immersed in a mercurial solution, this galvanic combination causes the precipitation of the mercury on the gold, which consequently contracts a white stain. In order to be sure that the stain is caused by mercury, the metal must be volatilized in a small tube, so as to obtain a characteristic globule. A minute portion of any of the preparations of mercury, either in the solid state or in concentrated solution, being placed on a bright plate of copper, and a drop of a strong solution of potassium iodide added, a silvery characteristic stain will immediately appear on the copper.

For further details regarding the detection of mercury in compounds or preparations containing it, see *Hydrargyri Chloridum Corrosivum.*

It is difficult to accurately weigh small specified quantities of metallic mercury. An ingenious method was suggested by H. Kral, which is as follows: It consists of using a goose quill, into which the necessary quantity of mercury has been weighed. A small hole is then cut immediately above the surface of mercury, and the apparatus is ready for use. By simply immersing it into the bottle containing the mercury, it is filled through the opening, and uniform quantities, sufficiently accurate for practical purposes, are thus easily measured. (*Ph. Centralh.*, 1895, 422, 423.) In pharmaceutical operations a medicine dropper may be used to transfer the mercury.

Uses.—Metallic mercury in bulk is not absorbable, but when in a finely divided condition or in combination as a salt, it is taken up from the alimentary tract. In what form it is absorbed is at present uncertain. There are two widely held views, one that it is converted into an albuminate which is soluble in an excess of protein matter, and the other that it forms in the intestinal tract an oxide which is dissolved by the fatty matters. After its absorption it escapes from the system chiefly through the kidneys, although it has been detected in practically every secretion of the body. The elimination is comparatively slow so that when used over long periods of time it tends to accumulate in the system and may be stored up in the body for long periods. When present in the blood in large amounts it acts as a local irritant to various glandular structures and leads to an increased secretion. The salivary glands are usually the most sensitive so that ptyalism is an early symptom of chronic mercurial poisoning, but both the kidney and bowels are frequently affected.

The effects of small quantities of mercury on the bodily functions are not positively known but it appears to act somewhat like arsenic, restraining destructive metabolism and thereby causing a tendency to increase in weight. A stimulating effect upon the blood making organs is often manifest by an increase in the number of red blood cells, but after toxic doses anemia may result apparently through destruction of the bone marrow. After large doses there is also a diminution in the fibrin content of the blood. Whether this latter change is caused by therapeutic quantities is at present uncertain, but the clinical effects seen in conditions attended with fibrinous exudate would lead one to believe that it does. Sulant (*J. A. M. A.*, 1922, lxxix, 2071) has found that large doses introduced into the blood stream are directly injurious to the heart muscle.

In the form of blue mass (see *Massa Hydrargyri*) and of calomel (see *Hydrargyri Chloridum Mitis*), mercury is used as a cathartic and in the latter form also as a diuretic. All of the soluble salts appear to be more or less actively germicidal, the bichloride being the most widely employed. In this place will be considered the effects of mercury upon the system which are common to all the preparations used internally.

The most marked constitutional effects from mercury are seen in *syphilis.* Its beneficial action in this affection is due to a direct toxic effect upon the spirochetes which are the cause of the disease. Under full mercurialism the obvious lesions of lues may disappear with great rapidity, but some of the germs remain hidden, so to speak, in the internal organs, especially in the central nervous system, and it is usually essential that the administration of mercury be continued for from one to two years. The generally accepted mode of using the metal is to give it in ascending doses until a mild degree of ptyalism is produced, then withdraw the metal for a few days to allow the system to clear itself of the excess and give it in doses just below that which caused salivation. In inflammatory diseases of the serous membranes, as *pleurisy, meningitis,* and *iritis,* especially when there is fibrinous exudate, mercury is often of the utmost value. In similar conditions involving mucous membranes—especially *enteritis*—while it appears to exercise more or less antiphlogistic action, its effects are much less striking.

The first observable signs of mercury inducing *ptyalism* are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable odor, called the mercurial fetor. The saliva at the same time becomes increased in quantity and more viscid, and, if the affection proceed, the gums, tongue, throat, and face become much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur, and the saliva flows in streams from the mouth. If the use of the metal be persisted in, as was formerly sometimes the custom, the devitalized tissue affording a favorable place for bacterial growth, extensive necrosis may follow.

In the *treatment* of ptyalism it should be remembered that the inflammation of the salivary glands is the result of an effort at excretion and those drugs, such as potassium iodide, which tend to hasten the elimination of the metal will aggravate the symptoms. The most important element of the treatment is local cleanliness. Antiseptic and astringent mouth washes should be frequently used and ulcerated spots may be touched with solutions of silver nitrate. If the flow of saliva is excessive full doses of atropine may be given. Irvin (*B. M. J.*, Jan. 31, 1921) asserts that the internal use of sulphur is of advantage both as a prophylactic and curative of mercurial ptyalism. Sodium thiosulphate has also been recommended (see under *Sodii Thiosulphas*).

In the foregoing observations we have described the ordinary effects of mercury, but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions characterized by a small and frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming debility. Mercury occasionally produces a peculiar eruption of the skin, which is described by writers under the various names of *hydrargyria, eczema mercuriale,* and *lepra mercurialis.* Those who work in mercury, and are, therefore, exposed to its vapor, such as looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders. The miners are often salivated.

HYDRARGYRUM AMMONIATUM.
U. S., Br.

AMMONIATED MERCURY Hydrarg. Ammon.
[White Precipitate, Mercurammonium Chloride]

"Ammoniated Mercury contains $HgNH_2Cl$, corresponding to not less than 78 per cent. and not more than 80 per cent. of Hg." *U. S.*

Hydrargyri Præcipitatum Album; Hydrargyrum Amidatobichloratum; Hydrargyrum Bichloratum Ammoniatum; Mercurius Præcipitatus Albus; Hydrargyri Ammonio-Chloridum; Ammoniochloride of Mercury, Mercuric Ammonium Chloride; Mercuric amido-chloride; Chloramidure de Mercure, Oxychlorure Ammoniacal de Mercure, Lait Mercuriel, Mercure Précipité Blanc, *Fr.;* Hydrargyrum praecipitatum album, *P. G.;* Weisser Quecksilberpräcipitat, Quecksilber-Chloridamid, *G.;* Cloramiduro di mercurio, *It.*

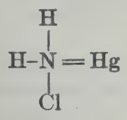
"Mercuric Chloride, 60 *grammes;* Solution of Ammonia, 80 *millilitres;* Distilled Water, *a sufficient quantity.* Dissolve the Mercuric Chloride in *twelve hundred millilitres* of Distilled Water with the aid of heat; pour the liquid into the Solution of Ammonia diluted with *four hundred millilitres* of Distilled Water, constantly stirring; collect the precipitate on a filter; wash it with *two hundred and fifty millilitres* of Distilled Water, and dry at a temperature not exceeding 30° C." *Br.*

No process is recognized by the U. S. P. X; the U. S. P. VIII process, which was essentially similar to the Br., may be found in the *U. S. D.*, 20th ed., p. 568.

The commercial varieties have at times differed somewhat from the present official preparation in composition, the formula being $N_2H_6HgCl_2$ (or *Mercur-diammonium chloride*). (See paper by F. X. Moerk, *A. J. P.*, 1888.)

Of the two possible formulas illustrated by the following:

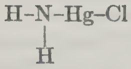
(1)



$\mathrm{H{-}\overset{\displaystyle H}{\underset{\displaystyle Cl}{N}}{=}Hg}$

and

(2)



$\mathrm{H{-}\underset{\displaystyle H}{N}{-}Hg{-}Cl}$

Saha and Choudberry (*Ztschr. Anorg. Chem.*, 1914, 86, 225) concluded that the second formula is the only tenable one, agreeing with certain experiments by which derivatives were formed.

Description and Physical Properties.—"White, pulverulent pieces, or a white, amorphous powder. It is odorless, and is stable in the air. Ammoniated Mercury is insoluble in water and in alcohol. By prolonged washing with water, it is gradually decomposed, assuming a yellow color and becoming converted into a basic salt. It is readily soluble in warm hydrochloric, nitric, and acetic acids and in a cold solution of ammonium carbonate. One Gm. is completely soluble in a cold solution of 5 Gm. of sodium thiosulphate in 5 cc. of water, with the evolution of ammonia. When the latter solution is heated for a short time, red mercuric sulphide is precipitated which upon protracted boiling turns black.

"At a temperature below a red heat Ammoniated Mercury is decomposed without fusion, and at a red heat it is volatilized. When heated with sodium hydroxide T.S., Ammoniated Mercury turns yellow, with the evolution of ammonia. A solution of Ammoniated Mercury in diluted nitric acid yields with potassium iodide T.S. a red precipitate, soluble in an excess of the reagent. The nitric acid solution yields a white precipitate with silver nitrate T.S.

"When volatilized at about 300° C., Ammoniated Mercury leaves not more than 0.2 per cent. of residue. Ammoniated Mercury is completely soluble in warm hydrochloric acid (*mercurous salts*) without effervescence (*carbonates*).

"**Assay.**—Dissolve about 0.5 Gm. of Ammoniated Mercury, accurately weighed, in 2 cc. of hydrochloric acid and 10 cc. of distilled water, warming gently until solution is effected, then dilute with 300 cc. of distilled water, and proceed as directed under *Hydrargyri Chloridum Corrosivum,* page 187, beginning with the word "Pass" in the third line of the Assay. The weight of mercuric sulphide obtained, multiplied by 0.862, indicates its equivalent in mercury (Hg). Each Gm. of Ammoniated Mercury corresponds to not less than 0.9047 Gm. and not more than 0.9279 Gm. of mercuric sulphide. Ammoniated Mercury may also be assayed by the electrolytic method."

"Preserve in well-closed containers, protected from light." *U. S.*

"A white, heavy, tasteless powder; insoluble in *alcohol* (90 per cent.) or *ether;* slowly decomposed by *water.* Digested with *solution of sodium hydroxide* it evolves ammonia, acquiring a pale yellow color, and the liquid, filtered and acidified with *nitric acid,* yields a white precipitate with *solution of silver nitrate.* Boiled with *solution of stannous chloride* it becomes grey, and yields globules of metallic mercury. Volatilises without fusing when sufficiently heated, leaving no appreciable fixed residue. When 0.3 gramme is triturated in a glass mortar with a few drops of *water,* and transferred to a flask with the aid of 40 millilitres of *water,* the mortar being finally rinsed with a solution of 2 grammes of *potassium iodide* in 10 millilitres of *water* and the rinsings added to the contents of the flask, then, the flask being securely closed and rotated frequently until solution is complete, the liquid thus obtained requires for neutralisation not less than 22.5 millilitres of *N/10 solution of hydrochloric acid, solution of methyl orange* being used as indicator (presence of not less than 94.5 per cent. of mercuric-ammonium chloride, NH_2HgCl)." *Br.*

Uses.—Ammoniated mercury is used only as an external application. It is a valuable remedy in parasitic skin diseases, such as *ringworm* or *favus,* and is also employed for destruction of *lice.* Mercur-diammonium chloride is said to produce an ointment more translucent and less white than the genuine, and more apt to become yellow on being kept.

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. For recovery after taking half a drachm, see *L. L.*, July 4, 1857. The remedies employed were an emetic of zinc sulphate and milk.

HYDRARGYRUM CUM CRETA.
U. S., Br.

MERCURY WITH CHALK Hydrarg. c. Cret.

"Mercury with chalk contains not less than 37 per cent. nor more than 39 per cent. of Hg." *U. S.*

Gray Powder; Æthiops Cretaceus; Mercure avec la Craie, Poudre de Mercure crayeux, *Fr.;* Quecksilber mit Kreide, *G.*

"Mercury, 38 Gm.; Honey, 10 Gm.; Prepared Chalk, 57 Gm.; Water, a sufficient quantity, to make 100 Gm. Weigh the mercury and honey successively into a strong bottle of the capacity of 100 cc. and add 2 cc. of water. Cork the bottle, and shake it for about half an hour at a time until the aggregate time of shaking reaches ten hours, or until the globules of mercury are no longer visible under a lens magnifying four diameters. The shaking may be more conveniently performed by mechanical means. Rub the prepared chalk with water in a mortar to a thick, creamy paste, and, having added the contents of the bottle, wash out the last portions with a little water, and triturate the whole to a uniform mixture. Finally dry the mixture, first between ample layers of bibulous paper, and afterwards in a dish at the ordinary temperature until it weighs 100 Gm. Then reduce it to a uniform powder without trituration." *U. S.*

"Mercury, 20 *grammes;* Prepared Chalk, 40 *grammes.* Triturate together in a porcelain mortar until the mixture acquires a uniform grey color and metallic globules cease to be visible to the naked eye." *Br.*

Dr. E. R. Squibb suggested the present official method of making mercury with chalk. The process is termed "succussion." When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic luster and becomes a dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens, and the mercury is said to be "extinguished." It was formerly thought that the metal was oxidized in the process. At present the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system with greater energy. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury in which the metal is extinguished by trituration, a very small portion is converted into mercurous oxide, while by far the greater part remains in the metallic state.

Robert B. Matter suggests an improved process for its preparation whereby labor and time are saved. It is as follows: "Mix twelve parts of finely powdered gum arabic with twelve parts of prepared chalk, triturate with sufficient water to form a rather thin paste, add thirty-eight parts of mercury, and continue the trituration until the globules of mercury have disappeared. Now add thirty-eight parts of finely powdered prepared chalk and sufficient water to form a thin paste, triturate, and when all the globules of mercury have disappeared, place the mortar in a hot water bath. The mixture distributed around the sides of the mortar will dry rapidly, when it can be easily scraped out, powdered in a clean mortar, passed through bolting cloth, or a fine sieve, and finally rubbed lightly in a clean dry mortar; 8 ounces may be made by this process in an hour." (*A. J. P.,* 1886, 119.)

Many modifications of the earlier processes suggested for the manufacture of this important preparation have appeared from time to time (see *U. S. D.,* 19th ed., p. 639), but the present official process is entirely satisfactory.

Description and Physical Properties.—"A light gray, rather damp powder, free from grittiness. It is odorless, and has a slightly sweet taste. Digest 0.1 Gm. of the powder with 20 cc. of warm acetic acid. The chalk dissolves with effervescence, and a residue of finely divided mercury remains.

"On filtering the mixture obtained in the preceding test, the filtrate becomes not more than slightly opalescent on the addition of a few drops of hydrochloric acid (*mercurous oxide*). Digest 0.1 Gm. of the powder with 20 cc. of warm diluted hydrochloric acid, and filter; the filtrate is not rendered more than slightly brown by hydrogen sulphide T.S. (*mercuric oxide*).

"**Assay.**—Dissolve about 1 Gm. of Mercury with Chalk, accurately weighed, in a mixture of 10 cc. of distilled water and 10 cc. of nitric acid, and heat on a water bath until red fumes cease to be evolved and the liquid becomes colorless. Then add 150 cc. of distilled water and 2 cc. of ferric ammonium sulphate T.S., and titrate the solution with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg. Mercury with Chalk may also be assayed by the electrolytic method.

"Preserve in well-closed containers, protected from light." *U. S.*

"A light-grey powder, free from grittiness; tends to aggregate into minute globules. Insoluble in *water;* partially dissolved by *diluted hydrochloric acid,* the residual mercury being left in a finely divided state; the filtered liquid does not yield any white or grey precipitate on the addition of *solution of stannous chloride* (absence of mercuric compounds)." *Br.*

As found in commerce, mercury with chalk, instead of being the mild preparation intended, sometimes acts very harshly causing vomiting, gastric pains, etc. This has been ascribed to the presence of antimony or arsenic, which, however, must be rare; the ordinary cause of the harshness is no doubt mercuric oxide, produced in minute proportion either during the trituration, or by the spontaneous change which occurs with time, mercurous oxide becoming mercuric oxide by the influence of light. The only sure method to guard against such results is to test the preparation carefully before dispensing it. (See official tests.) Another test for mercuric oxide is to treat a portion of the powder with diluted hydrochloric acid with a moderate heat, and add a solution of stannous chloride, which, if there be any mercuric oxide present, will cause a precipitation of metallic mercury as a black powder.

Uses.—Mercury with chalk is a very mild mercurial, similar in its properties to the blue mass, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-colored stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in *diarrhea.* Eight grains of the U. S. preparation contain about three grains of mercury. It should not be given in pill with substances which become hard on keeping, as the contraction of the mass presses together the particles of mercury, which in time appear in globules in the interior of the pill.

Dose, as an alterative, one-half to one grain (0.03–0.06 Gm.); as a laxative, four to ten grains (0.25–0.65 Gm.).

HYDRASTINÆ HYDROCHLORIDUM. N. F.

[HYDRASTINE HYDROCHLORIDE Hydrastin. Hydrochl. [Hydrastine Chloride]

"The hydrochloride of the alkaloid hydrastine [$C_{21}H_{21}O_6N.HCl$(419.75)]." *N. F.*

This salt, which was formerly recognized by the U. S. IX, is now official in the N. F. For method of isolating the alkaloid hydrastine, as well as for account of its chemical properties see under *Hydrastis.*

Description and Physical Properties.—"Hydrastine Hydrochloride occurs as a white to creamy-white powder, odorless and hygroscopic. It is very soluble in water and in alcohol; slightly soluble in chloroform; very slightly soluble in ether. An aqueous solution of the salt (1 in 20) is neutral or only slightly acid to litmus.

"An aqueous solution of the salt yields with silver nitrate T.S. a white precipitate insoluble in nitric acid, but soluble in ammonia water. Sulphuric acid, when added to Hydrastine Hydrochloride, produces a yellow color which turns to purple of heating. Sulphuric acid containing 0.005 Gm. of molybdic acid in each cc. produces a green color, changing to olive-green, then to brown; nitric acid produces a reddish yellow color; sulphuric acid containing 0.005 Gm. of selenous acid in each cc. gives a light green color changing to brown.

"No weighable ash remains on incinerating 0.1 Gm. of Hydrastine Hydrochloride. A solution of about 0.1 Gm. of Hydrastine Hydrochloride in 10 cc. of diluted sulphuric acid shows no blue fluorescence (*hydrastinine*) but on the gradual addition of potassium permanganate T.S., avoiding excess, a blue fluorescence develops. An aqueous solution of Hydrastine Hydrochloride (1 in 20) is not reddened by chlorine water (*berberine*).

"Preserve it in well-closed containers, protected from light." *N. F.*

Uses.—For account of the physiological action of this salt see under *Hydrastis.* It is used locally in various catarrhs and internally chiefly as a uterine stimulant, especially in hemorrhages of that organ.

Dose, from one-sixth to one-half grain (0.01–0.03 Gm.).

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.*

HYDRASTIS. U. S. (Br.)

HYDRASTIS [Golden Seal]

"Hydrastis consists of the dried rhizome and roots of *Hydrastis canadensis* Linné (Fam. *Ranunculaceæ*). Hydrastis yields not less than 2.5 per cent. of the ether-soluble alkaloids of Hydrastis and contains not more than 2 per cent. of its stems, or leaves, or more than 2 per cent. of other foreign organic matter, and yields not more than 3 per cent. of acid-insoluble ash." *U. S.* "Hydrastis Rhizome is the dried rhizome and roots of Hydrastis canadensis, *Linn.*" *Br.*

Hydrastis Rhizoma, *Br.;* Hydrastis Rhizome; Rhizoma Hydrastis; Golden Seal, Yellow Root, Yellow Puccoon, Orange Root, Indian Dye, Indian Turmeric, Ohio Turmeric; Indian Paint, Ground Raspberry, Eye Root, Eye balm, Yellow Eye, Jaundice Root; Hydrastis, *Fr. Cod.;* Racine d'Hydrastis du Canada, Sceau d'or, *Fr.;* Canadische Gelbwurzel, Gelbes Blutkraut, *G.;* Idraste, *It.;* Hidrastis del Canada (Rizoma de), *Sp.*

Hydrastis canadensis was known to the Cherokee Indians long before the discovery of America. They employed its underground portion alike for dyeing and as an internal remedy and made the early settlers acquainted with most of its valuable properties. Its rhizomes and roots were first introduced in the Secondary List of the U. S. P. in 1860 and have been recognized in all subsequent editions. It is a small, herbaceous, perennial plant, with a thick, fleshy, yellow rhizome, from which numerous long rootlets arise, and an erect, simple, pubescent stem from six inches to a foot or more in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to the stem a short distance below by a thick roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five, lobes, which are pointed and unequally serrate. A solitary greenish-white flower stands upon a peduncle rising from the base of the upper leaf. It is without corolla, but with a greenish-white calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound crimson berry, half an inch or more in diameter, composed of many fleshy carpels, each tipped with a short curved beak, and containing one or rarely two seeds. The plant is native to moist, rich woodlands of eastern North America, and at one time was abundant in the territory bordering the Ohio River from Illinois to Virginia. Most of the wild growing plants are now nearly exterminated, a few good stands persisting in West Virginia, Ohio, Kentucky and Indiana. The fruit bears a close resemblance to the raspberry, but is not edible. The Indians employed it for cuticle staining and dyeing their garments yellow under the name of *yellow puccoon,* and it is said to impart a rich and permanent yellow, and with indigo a fine green, to wool, silk, and cotton. There is but one other species of *Hydrastis* known—viz., *H. jezoensis* Sieb. et Zucc., which is found in northern Japan.

As the natural supplies of Hydrastis are becoming limited many experiments in the cultivation of hydrastis have been made. It can be grown from cuttings of the rhizome and from seed. It furthermore can be grown with the natural shade of the woodlands or by means of artificial shade. The important articles on the cultivation of hydrastis are the following: John Uri Lloyd, *Proc. A. Ph. A.*, 1905, p. 307, and in *A. Ph. A.*, vol. i, p. 5; Walter Van Fleet and G. Fred Klugh, *Circ. No. 6, Bureau of Plant Industry, U. S. Department of Agriculture;* J. C. Baldwin, *A. J. P.*, 1913, p. 147. Most of the commercial supplies are obtained from the Ohio Valley, Indiana contributing the largest quantity. The States producing hydrastis are Oregon, West Virginia, Ohio, Kentucky and Indiana. The chief market is Cincinnati.

Description and Physical Properties.—"*Unground Hydrastis.*—Rhizome subcylindrical, flexuous, from 1 to 5 cm. in length and from 2 to 10 mm. in thickness; more or less annulate and wrinkled longitudinally; yellowish-brown to dark grayish-brown; marked by numerous stem scars or occasional stem- or leaf-bases and numerous roots, frequently broken, leaving circular yellowish scars or short protuberances; fracture short and waxy; internally deep yellow or greenish-yellow; odor distinctive; taste bitter. Roots numerous, filiform, up to 35 cm. in length and 1 mm. in diameter; yellowish; brittle; curved, twisted and matted together or broken into pieces.

"*Structure.*—Rhizome: an epidermis or, more often, a brown, thin-walled, several-rowed cork, a cortex of about 25 rows of thin-walled parenchyma, frequently broken through by root formations; phloem and cambium usually collapsed and indistinct; 12 to 20 radially elongated fibro-vascular bundles separated by medullary rays, the latter up to 30 cells in width; large pith. Root: an epidermis of yellowish-brown, elongated cells with strongly suberized outer lamella and frequently developed into 1-celled root hairs; hypodermis of closely arranged suberized cells; cortex of about 12 rows of thick walled starch-bearing parenchyma; endodermis of slightly lignified cells; central fibro-vascular bundle of 2 to 6 rays, the tracheæ being strongly lignified.

"*Powdered Hydrastis.* — Brownish-yellow; fragments of starch-bearing parenchyma and fibro-vascular bundles; tracheæ small, with simple pores or spiral thickenings; lignified fibers from 0.2 to 0.3 mm. in length with thin walls and simple pores; fragments of reddish-brown, tabular-celled cork; numerous starch-grains from 0.002 to 0.015 mm. in diameter, nearly spherical, mostly single, a few 2- to 6-compound, the larger grains showing a central cleft; calcium oxalate crystals absent.

"Hydrastis moistened with water and mounted directly in sulphuric acid shows the formation of numerous acicular or rod-shaped crystals, some attaining a length of 0.2 mm.

"**Assay.**—Proceed by Type Process A, taking 10 Gm. of Hydrastis, in fine powder, using 100 cc. of ether and decanting an aliquot portion of 50 cc., representing 5 Gm. of Hydrastis. Use ether for the final extraction and determine the alkaloids gravimetrically (Proximate Assays)." *U. S.*

"Rhizome tortuous, simple or branched, from ten to forty millimetres long and from three to ten millimetres thick; yellowish-brown, becoming darker by age. On the upper surface, short ascending branches usually terminated by cup-shaped scars; on the lower surface and sides numerous thin, brittle roots. Fracture clean, resinous; fractured surface brownish-yellow or greenish-yellow. In transverse section, a ring of bright yellow, somewhat distant, wood-bundles. Slight but characteristic odor; taste bitter. Ash not more than 11 per cent." *Br.*

The color of the rhizome, though yellow in the recent root, becomes a dark yellowish-brown by age; that of the rootlets and the interior of the root is yellow, and that of the powder still more so.

Holm gives a valuable illustrated article on the morphology of the hydrastis plant in *Merck's Rep.*, xxii, p. 202. (See also *Chem. Zeit.*, 1894, p. 134.) Rosenthaler has extended his studies of microsublimates to that of hydrastis and finds that the pyroanalytical sublimate of hydrastis gives general alkaloidal reactions and a characteristic reaction with sulphuric acid. (*Ap. Ztg.*, xxviii, p. 991.)

While considerably adulterated in the past, the recent commercial supplies of hydrastis have been generally of good quality. The most common past adulterant has been the rhizome and rootlets of *Jeffersonia diphylla* (L.) Pers., commonly known as *Twinleaf*. This may be distinguished from hydrastis: (1) by its rhizome possessing scattered stone cells both isolated and in groups, broad bundles in young parts, separated by narrow medullary-rays which in older parts become united into a ring, (2) by its longer and thicker rootlets and (3) by the fracture of the dried rhizome which is lighter yellow.

Constituents.—It contains—besides albumen, starch, fatty matter, resin, yellow coloring matter, sugar, lignin, and various salts—three alkaloids, *hydrastine* (discovered by Durand in 1851), *berberine* (discovered by Mahla in 1862) and *canadine* (first isolated by Schmidt in 1888). Berberine is usually the most abundant, being present in proportions of from 3 to 4 per cent.

For a valuable paper by J. U. Lloyd on the preparation of salts of berberine, see *A. J. P.*, 1879, p. 11. Lerre's process based on Lloyd's for preparing hydrastine and berberine will be found in the *U. S. D.*, 19th ed., p. 643.

Wilhelm (*P. J.*, 1888, 325) furnishes a process for obtaining the alkaloids from hydrastis as follows: The extract obtained by treating the coarsely powdered root with water acidified with acetic acid at 37.8° C. is evaporated to a syrup and excess of diluted sulphuric acid added, when berberine sulphate separates. The filtrate neutralized with ammonia water gives a precipitate containing much hydrastine; this is separated, and on adding ammonia water in excess to the filtrate a further precipitate is produced, which contains *canadine.* Both precipitates, boiled with ethyl acetate, give solutions which, on cooling, deposit hydrastine in large crystals, somewhat colored, but rendered pure by recrystallization. The crystals from the second ammonia precipitate are much purer than those from the first; by slow evaporation of the ethyl acetate solution they can be obtained as large as walnuts.

Hydrastine.—This alkaloid was official in the U. S. IX. The hydrochloride is recognized by the N. F. and is described under its own name. The base, $C_{21}H_{21}O_6N$, was described as follows.

"Hydrastine occurs in white to creamy white, glistening prisms or as a white, micro-crystalline powder; permanent in the air. Hydrastine is almost insoluble in water; 1 Gm. is soluble in 170 mils of alcohol, 1.4 mils of chloroform, and in 175 mils of ether at 25° C., also in 22 mils of alcohol at 60° C.; freely soluble in benzene. Its saturated alcoholic solution is alkaline to litmus. It melts at about 131° C. Sulphuric acid produces a yellow color when added to Hydrastine; on heating the mixture, a purple color develops. Sulphuric acid containing 0.005 Gm. of molybdic acid in each mil gives with Hydrastine a green color, changing to olive-green and then to brown; nitric acid yields a reddish-yellow color; sulphuric acid containing 0.005 Gm. of selenous acid in each mil gives a light green color, changing to brown. No weighable ash remains on incinerating 0.1 Gm. of Hydrastine. A solution of about 0.1 Gm. of Hydrastine in 10 mils of diluted sulphuric acid shows no blue fluorescence (*hydrastinine*), but, on the gradual addition of potassium permanganate T.S., avoiding excess, a blue fluorescence develops. An aqueous solution of Hydrastine (1 in 20), made with the aid of a slight excess of diluted hydrochloric acid, is not reddened by chlorine water (*berberine*)." *U. S. IX.*

The name hydrastine must not be confused with the similar name of the eclectic preparation called *hydrastin,* which is an almost inert preparation made by collecting, washing, and drying the precipitate produced by pouring a concentrated alcoholic solution of the drug into a large volume of water.

Hydrastine has been shown to exist in appreciable amounts in the leaves and tops of the plant. Charles S. Herron (*Am. Drug.,* 1918, lxvi, 416) obtained nearly an ounce of this alkaloid from eight pounds of the dried material, which is about three quarters of one per cent.

LaWall (*Proc. Pa. Ph. A.,* 1912, p. 142) made separate assays of the rhizome and rootlets from a 98-pound lot of the drug. There was present 45.5 pounds of rhizome and 48 pounds of rootlets, the balance being dirt and waste. The rhizomes assayed 2.48 per cent. of hydrastine and the rootlets 1.38 per cent. The average of the entire lot was 1.92 per cent.

Berberine occurs in a considerable number of additional plants including Berberis, Xanthoxylum, Calumba, etc. It distinguishes itself from most alkaloids in that its crystals are a bright yellow color and yield yellow solutions with marked staining properties. It is soluble in 300 parts of water. For further description see *Berberis.*

Canadine ($C_{20}H_{21}O_4N$) was extracted by E. Schmidt; it occurs in the form of brilliant, small, white nodules, melting at 134° C. When canadine is dissolved in alcohol and treated with iodine, berberine hydriodide (which is yellow in color) is formed. Canadine was believed to be identical with dihydromethylberberine (*Ph. Post,* 1892, 230), and the formula $C_{21}H_{21}O_4N$ was given to it. E. Schmidt, however (*A. Pharm.,* 1894, 136–154), has found that its true formula is $C_{20}H_{21}O_4N$, and, owing to the fact that iodine forms with it berberine hydriodide, he believes that canadine is a *tetrahydroberberine.* Schmidt also obtained, as an additional product of the iodine reaction, the hydriodide of another base, which he believes is intermediate between berberine and canadine. For a process for isolating canadine, see *Proc. A. Ph. A.,* 1894, 1103. The alkaloid discovered by A. K. Hale, and obtained later by Burt and by Lerchen, and which was named *xanthopuccine,* is now considered to be identical with canadine. For processes for making hydrastine and berberine, see *D. C.,* 1897, 34. It is probable, from the odor of hydrastis, that besides the two alkaloids here mentioned it contains also an active volatile principle, but this has not yet been isolated.

Uses.—Hydrastis owes its virtues almost entirely to hydrastine, the alkaloid berberine, aside from some effect as a bitter, being practically inert. Hydrastine is an active alkaloid which is slowly absorbed and probably eliminated by the kidneys and lower bowel unchanged. When given to the lower animals it primarily stimulates the spinal motor cord, causing tetanic convulsions, with heightened reflexes, followed, if the dose has been large enough, by loss of reflex activity, and motor paralysis, which are probably in part due to depression of the motor centers, and are certainly, at least in part, the outcome of depression of the motor nerves and also of the muscles themselves. Death may occur in a convulsion from cramp-asphyxia, or later from simultaneous paralysis of the respiratory center and of the peripheral apparatus. The arterial pressure is first elevated and secondarily depressed; the first rise of pressure is probably due to the stimulation of the cardiac and arterial muscles; Pilcher and Sollmann (*J. P. Ex. T.,* 1915, vi, 391) have shown that it does not act on the nerves governing the vessels. The fall of pressure is the result of a direct paralytic action exerted upon the muscle fibers in the heart and in the arterioles. Hydrastine notably increases intestinal peristalsis, and, according to Fellner (*Arch. f. Gyn.*, 1906, lxviii), uterine contractions. It would seem to be a universal muscle poison, which acts upon both striated and non-striated muscle fibers in heart, arterioles, intestines, uterus, and generally throughout the body, its first stimulant action being followed by marked depression. Hydrastine has been shown by Fellner and Slavatinski to have a distinct ecbolic action, and premature labor is asserted to have been caused by its hypodermic administration.

Hydrastis has enjoyed a widespread reputation as a local remedy in various forms of *catarrh,* such as *rhinitis, gastritis, vaginitis,* and *urethritis.*

In chronic or subacute *inflammations* of the *colon* and *rectum* injections of hydrastis are often of great service, and it has been used in *hemorrhoids* with asserted excellent results.

The strength of the local application of hydrastis to be used in various diseases of the mucous membrane varies from five to twenty-five per cent. of the fluidextract. In *gonorrhea* from forty to eighty minims (2.5–5.0 cc.) of the fluidextract may be used to the fluidounce (30 cc.). In *hemorrhoids* from two to four drachms to the fluidounce may be used. The glycerite is not so useful a local preparation as the fluidextract diluted with water, a deposit of the insoluble resinous substance upon the mucous membrane and its constant prolonged influence being important.

There is some reason for believing that *berberine* has a special action upon the gastro-intestinal tract. Marfori has, however, found that even in large therapeutic dose it is without perceptible influence upon the circulation or the nervous system. When, therefore, a preparation of hydrastis is to be used for effects other than a local action on the gastro-intestinal or other mucous membrane, a salt of the pure alkaloid hydrastine should be used.

According to the studies of Falck and Guenste, berberine causes in dogs and rabbits restlessness, convulsive tremblings, hurried respiration, and diarrhea, followed, if the dose has been large enough, by decrease of the breathing rate, widespread paralysis, dyspnea, convulsions, and death. In man as yet no serious symptoms have been recorded as produced by it. Buchner is stated to have taken nearly twenty grains without causing anything more serious than a loose stool. Marek (*W. M. W.*, 1911, 2146) has presented evidence that it possesses oxytocic properties, and is useful in *delayed labor.* It has been employed in internal medicine as a simple bitter, in doses of from two to five grains (0.13–0.32 Gm.).

Canadine is said by Marfori to differ from berberine physiologically; it produces in moderate dose an increase in the blood pressure by stimulating the vasomotor center in the medulla. *Opianic, hydrastinic,* and *berberinic acids* are said by the same authority to be almost inert physiologically, except that they are feebly antiseptic. (*T. G.*, 1890.)

For a physiological study of the *methylamine* derivatives of hydrastine (*hydrastine methylamine*), see *V. A. P. A.*, cxlii, 1895.

The alkaloid hydrastine hydrochloride may be used in doses of from one-sixth to one-half grain (0.01–0.03 Gm.).

Dose, of hydrastis, fifteen to thirty grains (1–2 Gm.).

Off. Prep.—Extractum Hydrastis, *U. S.;* Fluidextractum Hydrastis, *U. S.* (*Br.*)*;* Tinctura Hydrastis, *U. S., Br.;* Mistura Rhei Alkalina (from Fluidextract), *N. F*

HYOSCYAMINÆ HYDROBROMIDUM. U. S.

HYOSCYAMINE HYDROBROMIDE Hyoscyamin. Hybrobr. [Hyoscyaminæ Hydrobromas, Pharm. 1890, Hyoscyamine Hydrobromate, Hyoscyamine Bromide]

"The hydrobromide [$C_{17}H_{23}O_3N.HBr$], an alkaloid obtained from hyoscyamus and other plants of the *Solanaceæ.*" *U. S.*

Hyoscyaminum Hydrobromicum; Bromhydrate d'Hyoscyamine, *Fr.;* Hyoscyaminhydrobromid, Bromwasserstoffsaures Hyoscyamin, *G.*

Although Brandes announced the existence of an alkaloid in the seeds of *Hyoscyamus niger,* the process which he used to obtain it was not successful in other hands. The credit of first isolating the alkaloid *hyoscyamine* from the plant must be given to Geiger and Hesse, who obtained it in 1833. Höhn and Reichardt's process, in which the seed is used as the source, is as follows. They treat hyoscyamus seed first with ether to separate fatty matter, then with alcohol acidulated with a few drops of sulphuric acid, and afterwards distil the alcoholic solution. The aqueous residue is to be neutralized with sodium hydroxide, and the liquid precipitated by a solution of tannin. The precipitate, having been placed on a porcelain plate to dry, is mixed while yet moist with an excess of lime, and then exhausted by strong alcohol. The alcoholic solution is treated with sulphuric acid, then with sodium hydroxide, and finally with ether, which dissolves the liberated hyoscyamine. By distilling off the ether a colorless oleaginous liquid is left, which at length solidifies.

These investigators originally gave to hyoscyamine the formula $C_{15}H_{23}O_3N$, but Ladenburg (*B. Chem. G.*, 1880, xiii) later showed by a study of its decomposition products that it is isomeric with atropine, $C_{17}H_{23}O_3N$. Hyoscyamine treated with boiling baryta water assimilates a molecule of water and splits up into the same decomposition products as atropine, *tropic acid* and *tropine.* Hyoscyamine is to-day regarded as a stereo-isomer of atropine, from which it differs in certain physical properties, notably in that it is lævorotatory to polarized light, while atropine is optically inert. Hyoscyamine is readily changed into the racemic form, atropine, by melting or by adding alkali to its cold alcoholic solution. For further details concerning its structure see under *Atropina.*

Hyoscyamine crystallizes in colorless, transparent, silky needles, fusing at 108.5° C., is inodorous, of an acrid, disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassium or sodium hydroxide is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming crystallizable salts.

Description and Physical Properties.—"White, odorless, deliquescent crystals. *Caution—Hyoscyamine Hydrobromide is extremely poisonous.* Hyoscyamine Hydrobromide is very soluble in water. One Gm. is soluble in 2.5 cc. of alcohol, 1.7 cc. of chloroform, and in 2260 cc. of ether, at 25° C.

"It melts at about 152° C. An aqueous solution of Hyoscyamine Hydrobromide is lævorotatory. Add 5 drops of nitric acid to about 0.01 Gm. of the salt, and evaporate to dryness in a porcelain dish on a water bath: the residue becomes violet upon the addition of alcoholic potassium hydroxide T.S Gold chloride T.S. added to about 1 cc. of an aqueous solution of the salt (1 in 20) produces a precipitate which, when recrystallized from a small quantity of boiling distilled water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (*difference from atropine and scopolamine*). Silver nitrate T.S. added to an aqueous solution of Hyoscyamine Hydrobromide produces a yellowish-white precipitate which is insoluble in nitric acid. Shake 2 cc. of chloroform with 1 cc. of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine T.S. have been added: the chloroform acquires a brownish color.

"An aqueous solution of Hyoscyamine Hydrobromide (1 in 20) is neutral to litmus paper. The ash from 0.1 Gm. is negligible. Platinic chloride T.S. does not form a precipitate in an aqueous solution of the salt (1 in 20) (*difference from most other alkaloids*). Dissolve about 0.05 Gm. of the salt in 1 cc. of sulphuric acid: the solution is not darker than faint yellow (*readily carbonizable substances*).

"Preserve in well-closed containers, protected from light." *U. S.*

Uses.—The physiological effects of hyoscyamine are qualitatively the same as those of its isomer atropine, although there is some difference quantitatively. Atropine, as pointed out elsewhere, is regarded as a mixture of dextro- and lævorotatory alkaloids. Cushny (*J. P.*, 1903, xxx, p. 177) has shown that the lævorotatory substance (hyoscyamine) is relatively more active in its paralyzing effect on nerve endings and less active in its stimulant action upon the central nervous system. Like atropine hyoscyamine checks secretion by paralyzing the terminals of nerves to the various glands, dilates the pupil by paralyzing the ends of the oculomotor nerve, and increases the pulse rate by paralyzing the pneumogastrics. The rise in blood pressure is comparatively small after hyoscyamine because it exercises but a feeble influence on the vasomotor center; similarly it causes but little increase in the respiration and shows less tendency to cause delirium. The former belief that hyoscyamine possessed narcotic properties was doubtless due to its contamination with scopolamine; there is no convincing evidence that chemically pure hyoscyamine has a depressant action upon the cerebrum. Clinically, hyoscyamine may be substituted for atropine wherever the action on peripheral nerves is desirable, as for instance, to check excessive secretion, to dilate the pupil, or to allay intestinal spasm.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

HYOSCYAMINÆ SULPHAS. Br.

HYOSCYAMINE SULPHATE

"Hyoscyamine Sulphate, $(C_{17}H_{23}O_3N)_2,H_2SO_4,2H_2O$, is the sulphate of an alkaloid, hyoscyamine, obtained from various plants belonging to the natural order Solanaceæ." *Br.*

Sulfate d'Hyoscyamine, *Fr.;* Hyoscyaminum Sulfuricum, Schwefelsaures Hyoscyamin, Hyoscyaminsulfat, *G.;*

Properties.—The British Pharmacopœia describes hyoscyamine sulphate as "a deliquescent crystalline powder. Soluble in 0.5 part of *water.* Melting point from 203° to 204° C. Yields the *reaction* characteristic of sulphates. When treated with *nitric acid* and *alcoholic solution of potassium hydroxide,* as described under 'Atropina,' a violet coloration is produced. 0.05 gramme, dissolved in 5 millilitres of *water* acidified with *hydrochloric acid,* yields with *solution of auric chloride* a yellow precipitate which, recrystallised from *water* acidified with *hydrochloric acid,* forms brilliant golden-yellow scales melting, when dried, at 165° C. Dissolves in *sulphuric acid* without coloration. No appreciable ash." *Br.*

Uses.—The medicinal properties and the dose of this salt of hyoscyamine are precisely those of the hydrobromide.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

HYOSCYAMUS. U. S. (Br.)

HYOSCYAMUS Hyosc. [Henbane, Hyoscyami Folium, P. I.]

"Hyoscyamus is the dried leaf with or without the tops of *Hyoscyamus niger* Linné (Fam. *Solanaceæ*). Hyoscyamus yields not less than 0.065 per cent. of the alkaloids of Hyoscyamus and contains not more than 25 per cent. of its stems none of which is more than 7 mm. in thickness. It yields not more than 12 per cent. of acid-insoluble ash." *U. S.* "Hyoscyamus Leaves are the leaves of Hyoscyamus niger, *Linn.*, collected from the flowering plants, and dried." *Br.*

Hyoscyami Folia, *Br.;* Hyoscyamus Leaves, Henbane Leaves, Black Henbane, Henbell, Stinking Nightshade, Insane Root, Poison Tobacco; Jusquiamus; Jusquiame noire, *Fr. Cod.;* Belene, Chenile, *Fr.;* Herba Hyoscyami, *P. G.;* Bilsenkraut, Bilsenkrautblätter, *G.;* Giusquiamo, *It.;* Beleno, *Sp.*

There are about fifteen species of the genus *Hyoscyamus* known; these are distributed from the Canary Islands over Europe and northern Africa to Asia.

Hyoscyamus niger, or *henbane,* varies in different regions, being either an annual or biennial plant. It possesses a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem of the biennial variety is erect, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulated, soft to the touch, and clasping at their base. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green color. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downward. They are composed of an urn-shaped calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. The corolla is of an obscure yellow color, beautifully variegated with purple veins. The fruit is a two-celled pyxis, invested with the persistent calyx, and contains numerous small seeds, which are discharged by the horizontal separation of the lid from the top portion of the fruit. The whole plant has a rank, offensive odor.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves shorter and less hairy and viscid, and the flowers often yellow without the purple streaks.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly cemeteries, old gardens, and the foundations of ruined houses. It is not, however, a native of this country, having been introduced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties were formerly cultivated in England, but at present the biennial is chiefly or solely grown. The annual plant flowers in July or August, the biennial in May or June. For an account of the cultivation of the biennial variety of Hitchin, England, see *P. J.*, Feb., 1860.

Mitlacher, in connection with other plants, has carried on a series of experiments on the cultivation of Hyoscyamus and reports on the results of his work in *Ph. Post,* 1911, p. 390 and *Zeit. Oest. Apoth. Ver.*, 1912, p. 401. Hyoscyamus has been successfully grown in the testing gardens of the Bureau of Plant Industry. There is usually some difficulty in growing hyoscyamus owing to its destruction by insects, but Newcomb was very successful with his experiments in Minneapolis. (*A. J. P.*, 1914, p. 531.) Schneider also has pointed out that henbane thrives well in California and says that it no doubt will do well in the Coast valleys. (*Pac. Pharm.*, iii, p. 192.) Peckoldt reports that *Hyoscyamus niger* grows wild in portions of Brazil. (*B. P. G.*, xix, p. 33.) Chevalier has shown that by cultivation the alkaloid content of hyoscyamus can be increased to 0.286 per cent. of total alkaloids. (*C. R. A. S.*, 1910, p. 344.) Experiments by Newcomb and Haynes (*A. J. P.*, 1916, lxxxviii, 1) show that *H. niger* cultivated in Minnesota yields very high percentages of total alkaloids, the range being from 0.096 to 0.1561 per cent. The biennial seeds were found to germinate more satisfactorily if first treated with strong sulphuric acid. The seeds are placed in a porcelain dish, the acid poured on them and they are stirred with a glass rod for two and one-half minutes. They are then thrown in a coarse screen and thoroughly washed with water. Seed thus treated gives a fairly uniform germination in from twelve to fifteen days.

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties. *Hyoscyamus muticus* L., of Egypt, is said to grow luxuriantly in the temperate zone and to produce a very much larger proportion of total alkaloids than does the official English plant, although the relative proportions of hyoscine and hyoscyamine are not the same. It appeared in the London market in the form of broken stalks with a few capsular fruits and traces of leaves and may become an important source of the alkaloids to the manufacturers.

Description and Physical Properties.—"*Unground Hyoscyamus.* — Usually much wrinkled, matted and broken, frequently consisting of leaves, stems, and flowering and fruiting tops. Leaves ovate or ovate-lanceolate, inequilateral, with petioles up to one-third the length of the blade, or sessile; apex acute, margin coarsely and angularly 1- to 4-toothed or lobed; hairy, densely so on the lower surface; upper surface dark green, lower surface light gray-green; stems from 2 to 7 mm. in thickness, cylindrical or somewhat compressed, longitudinally wrinkled, hairy, gray-green; flowers nearly sessile, with an urn-shaped, hairy, unequally 5-toothed calyx and a campanulate corolla, yellowish with purplish veins; fruit, a 2-locular pyxis enclosed in the calyx; odor distinctive; taste bitter and acrid.

"*Structure.*—Leaves: One layer of palisade cells with frequent large intercellular spaces;

some of the parenchyma cells with prisms or rosette aggregates of calcium oxalate; in the midrib a girdle or collenchyma about the vascular bundle and the parenchyma occasionally with sphenoidal microcrystals of calcium oxalate. Stems: Cortex thin; wood with numerous tracheæ and lignified fibers; hollow, with a few pith parenchyma cells. Seed: Campylotropous, the coat strongly reticulated, with curved embryo embedded in the endosperm.

"*Powdered Hyoscyamus.*—Grayish-green to dark green. Non-glandular hairs unicellular to 10-celled; glandular hairs with 1- to 4-celled stalk and 6 or more cells in the head; calcium oxalate crystals in single or twin monoclinic prisms or in rosette aggregates from 0.010 to 0.025 mm. in diameter, occasionally in sphenoidal crystals from 0.006 to 0.012 mm. in length; sclerenchyma fibers attaining a length of 1 mm. and a width of 0.030 mm., some with wavy walls and ends variously forked; pollen grains nearly smooth with 3 radiating furrows having a pore in the median part of each furrow, when dry or in alcohol distinctly elliptical and approximately 0.035 by 0.050 mm., but in water spherical and about 0.040 mm. in diameter; epidermal cells of the seed coat with radial and inner walls greatly thickened and incrusted with granular crystals of silicic acid.

"**Assay.**—Proceed by Type Process B, taking 25 Gm. of Hyoscyamus, in fine powder, using ether-chloroform mixture for percolating the drug and chloroform for the final extraction of the alkaloids. Determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.02893 Gm. of the alkaloids of Hyoscyamus (Proximate Assays)." *U. S.*

"Pale green, varying in length but seldom exceeding twenty-five centimetres; mostly sessile; exstipulate, triangular-ovate or ovate-oblong, acute, undulated, irregularly toothed, sinuate or pinnatifid, with conspicuous midrib. On both surfaces, but particularly on the under surface and near the veins, long uniserial hairs terminating in pluricellular glands. In the mesophyll prismatic and cluster-crystals of calcium oxalate." *Br.*

Much of the efficacy of hyoscyamus depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, according to Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are then obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in commerce. The root also is said to be much more poisonous in the second year than in the first.

The recent leaves have, when bruised, a strong, disagreeable, narcotic odor, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acrid. When dried, they have little odor or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odor.

Much of the henbane of commerce is taken from the plant in the first year of its growth. The drug of the market is very variable, frequently containing an excess of sand and the leaves of other species of hyoscyamus. It has recently been admixed with *H. muticus,* a plant growing in Egypt. The latter is readily determined by the presence of characteristic branching non-glandular hairs which are found on both the stems and leaves. (See *A. J. P.,* 1908, p. 361.) The commercial supplies of Hyoscyamus come chiefly from Europe through London.

The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray color, of the odor of the plant, and of an oleaginous, bitterish taste. From experiments made by Hirtz upon the relative medicinal power of extracts from the seeds and from the leaves, he inferred that the former had ten times the strength of the latter. Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Geiger and Hesse (1833) were the first to demonstrate the existence of an alkaloid in hyoscyamus. Ladenburg stated in 1880 that there are two alkaloids in the plant,—one crystallizable, *hyoscyamine* $C_{17}H_{23}O_3N$, and the other amorphous, *hyoscine* $C_{17}H_{21}O_4N$ (see *Scopolamina Hydrobromidum* and *Hyoscyaminæ hydrobromidum*). Höhn (*Ann. Ch. Ph.,* clvii, 98) obtained from the seeds a bitter principle which proved to be a glucoside. He calls it *hyoscypicrin,* and gives it the formula $C_{27}H_{52}O_{14}$. The hyoscyamine is the dominant alkaloid. The leaves contain a large proportion of potassium nitrate, F. Mahla having obtained approximately 2 per cent. of that salt. (*A. J. P.,* 1859, p. 402.)

Uses.—The physiological and therapeutic effects of Hyoscyamus are dominated by the alkaloid hyoscyamine and are therefore very similar to those of belladonna. Many physicians believe, however, that the action of the chief alkaloid is modified by the presence of scopolamine and that the plant, therefore, not only has the antispasmodic and drying effects of belladonna but that it has a distinct central narcotic action; the proportion of scopolamine, however, seems too small to exert any important influence. Its most important use is in relief of painful spasmodic affections of the unstriped muscle, as in *lead colic* and *irritable bladder.* It is also employed to allay nervous irritation, as in various forms of *hysteria* or *irritable cough,* but is inferior to scopolamine for these purposes. Externally cataplasms or fomentations of the fresh leaves have been employed to allay pain in *cancerous ulcers* and *hemorrhoids,* but its employment for this purpose is of doubtful advantage.

Hyoscyamus is preferably given in the form of the fluidextract or tincture. The inspissated juice of the fresh leaves (*Extractum hyoscyami viride*, Br.) is exceedingly variable in its operation and is not to be recommended.

Dose, of the leaves, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Extractum Hyoscyami, *U. S., Br.;* Fluidextractum Hyoscyami, *U. S.;* Pilula Colocynthidis et Hyoscyami (from Extract), *Br.;* Tinctura Hyoscyami, *U. S., Br.;* Pilulæ Catharticæ Vegetabiles (from Extract), *N. F.;* Pilulæ Colocynthidis et Hyoscyami (from Extract), *N. F.;* Pilulæ Laxativæ Post Partum (from Extract), *N. F.*

IGNATIA. N. F.

IGNATIA Ignat. [Saint Ignatius' Bean, Ignatia Amara

"Ignatia is the dried ripe seed of *Strychnos Ignatii* Bergius (Fam. *Loganiaceæ*). Ignatia yields not less than 2 per cent. of the alkaloids of Ignatia and not more than 1 per cent. of foreign organic matter." *N. F.*

Semen Ignatiæ, Faba Ignatii, Faba Sancti Ignatii, *Lat.* Fève igasurique, Fève de Saint Ignace, *Fr.;* Ignatiusbohne Bittere Fiebernuss, Ignazbohnen, *G.;* Fava di Santo Ignazio *It.;* Haba de Santo Ignacio, *Sp.*

Strychnos Ignatia Berg. (*Ignatia amara* L. f.) is a large climbing shrub, a native of the Philippine Islands, and introduced into Cochin-China where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honored with the name of their founder. The fruit is a large ovoid berry being from 5 to 6 inches long and containing from 12 to 24 seeds imbedded in its pulp. The commercial supplies of the seeds come from the Philippine Islands. Flückiger and Arthur Meyer have found that the seed has a close structural analogy to nux vomica. (*P. J.*, 1881, 1.)

Description and Physical Properties.—"*Unground Ignatia.*—Angularly ovate with obtuse angles or irregularly several sided; up to 30 mm. in length and about 15 mm. in breadth and thickness; externally grayish and reddish brown to dark reddish brown or blackish, nearly smooth and with but few hairs; heavy and very hard; fracture granular; translucent in small fragments; a small irregular cavity in the center contains the small embryo. Nearly inodorous and intensely bitter.

"*Structure.*—An epidermal layer of cells with yellowish, granular contents and yellowish walls thickened on the outer side; the remainder of the seed coat made up of about six rows of thin-walled cells; the outer cells of the endosperm tissue, small, the inner large and with thickened walls.

"*Powdered Ignatia.*—Light gray to grayish brown, and exhibits thin brown cells of the epidermis and the subjacent layer of the seed coat; polygonal cells with thickened, pitted walls and granular contents from the endosperm; hairs, few, in spreading clusters, characteristic, thickened at base and having linear markings; embryo tissue of small thin-walled cells.

"**Assay.**—Place 10 Gm. of Ignatia, in fine powder, in a 250 cc. bottle, add 100 cc. of ether-chloroform mixture, and proceed by Type Process A. Decant 50 cc. of the ethereal solution to complete the assay, using chloroform as the immiscible solvent in shaking out the alkaline liquid, and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.0364 Gm. of the alkaloids of Ignatia." *N. F.*

To Pelletier and Caventou Ignatia beans yielded the same constituents as nux vomica, and, among them, 1.2 per cent. of strychnine and 0.5 per cent. of brucine.

The medicinal uses are the same as those of nux vomica.

Dose, one to two grains (0.06–0.12 Gm.).

Off. Prep.—Extractum Ignatiæ, *N. F.;* Tinctura Ignatiæ, *N. F.*

INFUSA. U. S.

INFUSIONS

Ptisana, Tisanes, Infusions, *Fr.;* Infusa, *P. G.;* Infusionen, Aufgüsse, *G.;* Infusi, *It.;* Infusiones, *Sp.*

These are aqueous solutions obtained by treating drugs with water (without the aid of ebullition). The water employed may be hot or cold according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance and macerating the mixture in a tightly closed vessel until the liquid cools.

The U. S. provides that, when not otherwise specified, infusions shall be of 5 per cent. strength and gives the following general formula for infusions:

"Infusions must be freshly made, and, when their strength is not otherwise directed, they are to be prepared by the following general formula:

"The Drug, coarsely comminuted, 50 Gm.; Water, a sufficient quantity to make 1000 cc. Introduce the drug into a suitable vessel provided with a cover, pour upon it 1000 cc. of boiling water, cover the vessel tightly, and allow it to stand for half an hour. Then strain with pressure, and pass enough water through the strainer to make the Infusion measure 1000 cc. If the activity of the Infusion is affected by heat, cold water only should be used.

"*Caution.—The strength of infusions of energetic or powerful drugs should be specially directed by the physician.*" *U. S.*

Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Vessels of block-tin are generally well adapted for the purpose.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. Sterilization of infusions by heating them to the boiling point, then preserving in bottles which have been kept hot to destroy germs, and stoppered with sterilized cotton, is effective, particularly if the bottles have a stopcock near the bottom to draw the infusion when wanted.

Concentrated infusions of the strength of 50 per cent. were introduced into the British Pharmacopœia (1898); they are mostly made by percolation, and were termed "Liquors." This certainly led to confusion in nomenclature, and it is difficult to understand why they were not called concentrated infusions, particularly as their almost universal use is for making ordinary infusions by diluting with water. They were dropped from the British Pharm. 1914.

INFUSUM ALSTONIÆ. Br.

INFUSION OF ALSTONIA

"Alstonia, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain while hot." *Br.*

See *Alstonia.*

Dose, one-half to one fluidounce (15–30 cc.).

INFUSUM AURANTII. Br.

INFUSION OF ORANGE PEEL

Tisane d'Ecorce d'Orange, *Fr.;* Pomeranzenschalenaufguss, *G.*

"Dried Bitter-Orange Peel, cut small, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

A grateful stomachic.

Dose, from one-half to one fluidounce (15–30 cc.).

INFUSUM AURANTII COMPOSITUM. Br.

COMPOUND INFUSION OF ORANGE PEEL

Tisane d'Ecorce d'Orange composée, *Fr.;* Pomeranzen und Citronenschalenaufguss, *G.*

"Dried Bitter-Orange Peel, cut small, 25 *grammes;* Lemon Peel, cut small, 10 *grammes;* Cloves, bruised, 5 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

A grateful stomachic in the *dose* of from one-half to one fluidounce (15–30 cc.).

INFUSUM BUCHU. Br.

INFUSION OF BUCHU

Infusum Diosmæ, s. Barosmæ; Tisane de Buchu, *Fr. Cod.;* Buchuaufguss, *G.*

"Buchu Leaves, freshly broken, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

It has the odor, taste, and medicinal virtues of the leaves, and affords a convenient method of administering the medicine.

Dose, from one to two fluidounces (30–60 cc.).

INFUSUM CALUMBÆ. Br.

INFUSION OF CALUMBA

Infusion of Columbo; Tisane de Columbo, *Fr.;* Kolombo-Infusion, Kolomboaufguss, *G.;* Infusion de Colombo, *Sp.*

"Calumba Root, cut small, 50 *grammes;* Distilled Water, cold, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain." *Br.*

The *infusion of calumba* is likely to spoil very quickly, especially in warm weather. Calumba contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change, but the former is much the more permanent of the two. Hence it is, according to Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen which has escaped coagulation. According to these views, the best plan of preparing infusion of calumba is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*A. J. P.,* xviii, 141; from *P. J.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless the plan of preparing the infusion above proposed is probably the best. The infusion of calumba is not colored by salts of iron, and may be conveniently administered in connection with them.

Dose, from one-half to one fluidounce (15–30 cc.).

INFUSUM CARYOPHYLLI. Br.

INFUSION OF CLOVES

Tisane de Girofle, *Fr.;* Gewürznelken-Infusion, Gewürznelkenaufguss, *G.*

"Cloves, bruised, 25 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The infusion of cloves affords precipitates with lime water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (Phillips.)

Dose, one fluidounce (30 cc.).

INFUSUM CASCARILLÆ. Br.

INFUSION OF CASCARILLA

Tisane de Cascarille, *Fr.;* Kaskarillaufguss, *G.*

"Cascarilla, in No. 10 powder, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

This infusion affords precipitates with lime water, infusion of galls, silver nitrate, lead acetate and subacetate, zinc sulphate, and ferrous sulphate.

Dose, one fluidounce (30 cc.).

INFUSUM CHIRATÆ. Br.

INFUSION OF CHIRETTA

Tisane de Chirette, *Fr.;* Chirettaufguss, *G.*

"Chiretta, cut small, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

Dose, from one-half to one fluidounce (15–30 cc.).

INFUSUM CINCHONÆ ACIDUM. Br.

ACID INFUSION OF CINCHONA

Infusion of Yellow Bark; Infusion of Calisaya Bark; Tisane de Quinquina jaune, *Fr.;* Kalisaya-Rindenaufguss, *G.*

"Red Cinchona Bark, in No. 40 powder, 50.0 *grammes;* Aromatic Sulphuric Acid, 12.5 *millilitres;* Distilled Water, boiling, 1000.0 *millilitres.* Mix the Red Cinchona Bark with the Distilled Water in a covered vessel; add the Aromatic Sulphuric Acid; infuse for one hour; strain while hot." *Br.*

Although the infusion with boiling water is more quickly prepared than the infusion with cold water, and therefore better adapted to cases of emergency, yet the former is a more elegant preparation, not turbid like the latter, and at least equally efficient. We therefore prefer the process of the U. S. Pharmacopœia, 1890, provided it be skilfully conducted. (See *U. S. Dispensatory,* 19th ed., p. 654.)

Dose, one fluidounce (30 cc.).

INFUSUM DIGITALIS. U. S., Br.

INFUSION OF DIGITALIS Inf. Digit.

Infusion of Foxglove; Tisane de Digitale, *Fr.;* Fingerhutaufguss, Digitalisaufguss, *G.;* Infusion de digital, *Sp.*

The U. S. Pharmacopœia has abandoned the antiquated direction to use "bruised" digitalis and now agrees with the Br. in directing that the leaves be in a powdered form, although it differs from the Br. in strength, requiring two and a half times the proportion of drug.

"Digitalis, in fine powder, 15 Gm.; Alcohol, 100 cc.; Cinnamon Water, 150 cc.; Boiling Water, 700 cc.; Cold Water, a sufficient quantity to make 1000 cc. Upon the digitalis, contained in a suitable vessel, pour the boiling water, tightly cover, and allow it to macerate for one hour. Filter, add the alcohol and cinnamon water to the filtrate, and pass enough cold water through the residue on the filter to make the product measure 1000 cc. Mix well." *U. S.*

"Digitalis Leaves, in No. 20 powder, 7 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

It has long been recognized that infusion of digitalis as ordinarily made is an unstable preparation, but according to Hatcher and Eggleston (*J. A. M. A.,* 1915, lxv) this would seem to be due to bacterial action, for they find that if bottled hot and kept stoppered, the infusion will retain its strength for many weeks.

Many clinicians have believed that the infusion of digitalis differed in its action to some extent from that of the tincture; especially that the infusion was more actively diuretic. It has long been surmised that the formerly official method of preparing infusion of digitalis did not entirely extract the potency of the leaf; Bliss (*J. Lab. Clin. Med.,* 1922, vii, 225) found that 10 samples of an infusion prepared at various retail pharmacies showed, on the average, a potency of less than 40 per cent. of the leaf from which they were made. In 1910 Focke (*A. Pharm.,* ccxlix, 323) showed that it was possible to extract 85 per cent. of the activity of digitalis leaf with water. Weiss and Hatcher (*J. A. M. A.,* 1921, lxxvi, 508) suggested a new method of preparing an infusion of digitalis that more completely exhausted the leaf and yielded a uniform product and which they assert maintains its activity unimpaired, if kept hermetically sealed, for years. A method very similar to this was adopted in the present revision of the U. S. Pharmacopœia. As this method more thoroughly extracts the drug the present preparation, despite the fact the proportion of leaf has not been altered, will be found to be somewhat stronger than the former infusion.

Dose, of the U. S. infusion, one-half to three fluidrachms (2–11 cc.).

The British infusion is much weaker and may be given in doses of two to six fluidrachms (7.5–22.5 cc.).

INFUSUM ERGOTÆ. Br.

INFUSION OF ERGOT

Tisane de Seigle ergoté, *Fr.;* Mutterkornaufguss, *G.*

"Ergot, freshly crushed, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

As ergotoxin is not soluble in water this preparation does not fully represent the virtues of ergot.

Dose, two fluidounces (60 cc.).

INFUSUM GENTIANÆ COMPOSITUM. Br.

COMPOUND INFUSION OF GENTIAN

Tisane de Gentiane composée, *Fr.;* Enzianaufguss, *G.*

"Gentian Root, thinly sliced, 12.5 *grammes;* Dried Bitter-Orange Peel, cut small, 12.5 *grammes;* Lemon Peel, cut small, 25.0 *grammes;* Distilled Water, boiling, 1000.0 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The National Formulary recognizes a compound infusion of gentian which is made with a menstruum containing about 21 per cent. of alcohol and is more than twice the strength of the British. (See Part III.)

The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very prone to spoil. The alcohol has, however, been abandoned by the British Pharmacopœia, and lemon peel substituted.

Dose, from one-half to one fluidounce (15–30 cc.).

INFUSUM KRAMERIÆ. Br.

NFUSION OF KRAMERIA

Infusion of Rhatany; Tisane de Ratanhia, *Fr.;* Ratanhiawurzelaufguss, *G.*

"Krameria Root, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The *infusion of rhatany* is undoubtedly most efficient when prepared from the root in a state of moderately coarse powder by the mode of percolation with cold water, as directed in the U. S. process of 1870.

Dose, of the infusion, from one to two fluidounces (30–60 cc.).

INFUSUM QUASSIÆ. Br.

INFUSION OF QUASSIA

Tisane de Quassie, *Fr.;* Quassiaaufguss, *G.;* Infusion de cuasia amarga, *Sp.*

"Quassia Wood, rasped, 10 *grammes;* Distilled Water, cold, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Boiling water may be employed when it is desirable to obtain the preparation quickly, but cold water affords a clearer infusion. The fifteen minutes' maceration directed in the British Pharmacopœia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood.

This preparation is used by mouth as a bitter tonic and by enema in the treatment of seat-worms.

Dose, from one-half to one fluidounce (15–30 cc.).

INFUSUM RHEI. Br.

INFUSION OF RHUBARB

Tisane de Rhubarbe, *Fr.;* Rhabarberaufguss, *G.;* Infuso di rabarbaro, *It.;* Infusion de ruibarbo, *Sp.*

"Rhubarb, in thin slices, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the source of heat, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamon, fennel seed, or nutmeg, which improves the taste of the infusion and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a laxative, and is occasionally used as a vehicle for tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it.

Dose, one-half to one fluidounce (15–30 cc.).

INFUSUM ROSÆ ACIDUM. Br.

ACID INFUSION OF ROSES

Tisane de Rose composée, *Fr.;* Saurer Rosenaufguss, *G.*

"Red-Rose Petals, dried and broken, 25.0 *grammes;* Diluted Sulphuric Acid, 12.5 *millilitres;* Distilled Water, boiling, 1000.0 *millilitres.* Add the Diluted Sulphuric Acid to the Distilled Water; infuse the Red-Rose Petals in the mixture in a covered vessel for fifteen minutes; strain while hot." *Br.*

The formula of the N. F. for *Infusum Rosæ Compositum* (see Part III) is preferable to that of the Br. Pharm. on account of the presence of sugar.

The red rose serves little other purpose than to impart a fine red color and a slight rose and astringent flavor to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. According to J. B. Barnes, one part of glycerin added to eight or nine parts of infusion of rose increases greatly its brightness and transparency. It is refrigerant and astringent, and affords a useful and not unpleasant drink in *hemorrhages* and *colliquative sweats.* It is much used by British practitioners as a vehicle for saline medicines particularly magnesium sulphate, the taste of which it serves to cover. It is also employed as a gargle in combination with more active drugs.

Dose, one-half to one fluidounce (15–30 cc.).

INFUSUM SCOPARII. Br.

INFUSION OF BROOM

Tisane de Genêt à balais, *Fr.;* Besenginsteraufguss, *G.*

"Broom Tops, dried and bruised, 100 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

This preparation has been introduced in place of the Decoction of Broom of the British Pharmacopœia of 1885. Water thoroughly extracts the virtues of broom, and the large quantity of water in each dose aids the diuretic action.

Dose, from one to two fluidounces (30–60 cc.).

INFUSUM SENEGÆ. Br.

INFUSION OF SENEGA

Tisane de Polygale de Virginie, *Fr.;* Senegaaufguss, *G.*

"Senega Root, in No. 10 powder, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain while hot." *Br.*

Dose, one fluidounce (30 cc.).

INFUSUM SENNÆ. Br.

INFUSION OF SENNA

Senna Tea; Tisane de Séné, *Fr.;* Sennaaufguss, *G.*

"Senna Leaves, 100 *grammes;* Ginger, sliced, 5 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

We prefer the coriander of the U. S. P. 1870 to the ginger of the British. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to prescribe with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. (See *Infusum Sennæ Compositum.*) The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste.

Dose, one to two fluidounces (30–60 cc.).

Off. Prep.—Mistura Sennæ Composita, *Br.*

INFUSUM UVÆ URSI. Br.

INFUSION OF BEARBERRY

Tisane d'Uv Ursi, *Fr.;* Bärentraubenblätteraufguss, *G.*

"Bearberry Leaves, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

Dose, from one to two fluidounces (30–60 cc.), three or four times a day.

INJECTIO APOMORPHINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF APOMORPHINE

Injection hypodermique d'Apomorphine, *Fr.;* Subcutane Apomorphineinspritzung, *G.;* Inyeccion Hipodermica de Cloruro de Apomorfina, *Sp.*

"Apomorphine Hydrochloride, 1 *gramme;* Diluted Hydrochloric Acid, 1 *millilitre;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Mix the Diluted Hydrochloric Acid with fifty millilitres of the Distilled Water; dissolve the Apomorphine Hydrochloride in the mixture, and add sufficient of the Distilled Water to produce the required volume. This injection should be recently prepared. 100 millilitres contain 1 gramme of Apomorphine Hydrochloride; 110 minims contain 1 grain." *Br.*

Dose, by subcutaneous injection, from two to eight minims (0.12–0.5 cc.).

INJECTIO COCAINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF COCAINE

Injection Hypodermique de Cocaine, *Fr.;* Subcutane Cocaineinspritzung, *G.;* Inyeccion Hipodermica de Cloruro de Cocaina, *Sp.*

"Cocaine Hydrochloride, 5.00 *grammes;* Salicylic Acid, 0.15 *gramme;* Distilled Water, 100.0 *millilitres,* or *a sufficient quantity.* Boil the Distilled Water; add the Salicylic Acid; dissolve the Cocaine Hydrochloride in the solution when cool; add, if necessary, sufficient recently boiled and cooled Distilled Water to produce one hundred millilitres of the Injection. This Injection is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. It contains 5 grammes of Cocaine Hydrochloride in 100 millilitres; 110 minims contain 5 grains." *Br.*

Dose, by subcutaneous injection, from two to ten minims (0.12–0.6 cc.).

INJECTIO ERGOTÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF ERGOT

Hypodermic Injection of Ergotin; Injection hypodermique d'Ergot de Seigle, *Fr.;* Subcutane Mutterkorneinspritzung, *G.;* Inyeccion Hipodermica de Ergotina, *Sp*

"Extract of Ergot, 33 *grammes;* Phenol, 1 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Dissolve. This Injection should be recently prepared. 100 millilitres contain 33 grammes of Extract of Ergot; 110 minims contain 33 grains." *Br.*

This preparation does not fully represent ergot. (See *Ergota.*)

Dose, by subcutaneous injection, from three to ten minims (0.2–0.6 cc.).

INJECTIO MORPHINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF MORPHINE

Injection hypodermique de Morphine, *Fr.;* Subcutane Morphineinspritzung, *G.*

"Morphine Tartrate, 2.5 *grammes;* Distilled Water, recently boiled and cooled, sufficient to produce 100.0 *millilitres.* Dissolve. This Injection is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. It contains 2.5 grammes of Morphine Tartrate in 100 millilitres; 110 minims contain 2.5 grains." *Br.*

This solution is made from morphine tartrate in place of the morphine acetate formerly used; this is a great improvement, as the acetate is the most unstable of all morphine salts.

Dose, by subcutaneous injection, from five to ten minims (0.3–0.6 cc.).

INJECTIO STRYCHNINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF STRYCHNINE

"Strychnine Hydrochloride, 0.75 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100.0 *millilitres.* Dissolve. This Injection contains 0.75 gramme of Strychnine Hydrochloride in 100 millilitres; 110 minims contain ¾ grain." *Br.*

Dose, by subcutaneous injection, five to ten minims (0.3–0.6 cc.).

INJECTIONES HYPODERMICÆ

HYPODERMIC INJECTIONS

Under this head are classed preparations which are recognized in the British Pharmacopœia for hypodermic application. These preparations are really of very little value, on account of their proneness to undergo decomposition, and the difficulty of maintaining their sterility, and are greatly inferior to the *hypodermic tablets* of various strengths which are now supplied by manufacturing pharmacists. These tablets should be made official, since their convenience, permanence, and accuracy in weight have caused them to come into universal use. The selection of the diluent is an important question; very finely powdered cane sugar has been employed, but is apt to produce local irritation and even abscesses. Sodium chloride has also been recommended, but the best diluent seems to be dried neutral sodium sulphate.

The recent practice of supplying hypodermic solutions and ampules removes some of the objections to this class of preparations (see *Ampullæ,* Part III.)

INULA. N. F.

INULA [Elecampane]

"Inula consists of the dried rhizome and roots of *Inula Helenium* Linné (Fam. *Compositæ*). Inula contains not more than 5 per cent. of its stem bases or more than 2 per cent. other foreign organic matter." *N. F.*

Elecampane, Aunee, Racine d'Aunee, Oeil de Cheval, *Fr;* Alantwurzel, *G;* Enula Campana, *It., Sp.*

Inula Helenium is a stout, perennial herb naturalized from Europe and growing along roadsides and damp pastures from Nova Scotia to North Carolina and westward as far as Missouri. From a large fleshy, fusiform branching rhizome there arises a stout branching stem which attains a height of about 6 feet and a rosette of radical leaves. The stem leaves are alternate, partly clasping, cordate-oblong, woolly on lower surface with unequally serrate margins. The flowers occur during summer in golden-yellow heads, each consisting of a naked receptacle bearing yellow, pistillate, ligulate florets along the margin and a central disk of yellow perfect, tubular florets. The exterior of the receptacle is covered by an imbricated involucre, the outer bracts of which are leaf-like. The fruit is a 4-5 ribbed achene. The rhizome and roots should be collected in August of the second year, cut into slices and carefully dried. Since the dried drug is particularly subject to insect attack, it should be preserved in air-tight containers to which a few drops of carbon tetrachloride may be added from time to time as an insecticide. Most of the drug used in the United States is imported from Europe through Rotterdam and Trieste.

Inula has at times been adulterated with stems and foreign roots. Commercial supplies are occasionally mouldy due to carelessness in drying. Most of the imported drug is consumed by proprietary medicine manufacturers.

Description and Physical Properties.—"*Unground Inula.*—Rhizome usually split into longitudinal or more or less oblique pieces to which may be attached one or more of the roots; up to 8 cm. long and 4 cm. in diameter; externally grayish brown to dark brown, longitudinally wrinkled with occasional buds or stem scars and surmounted at the crown by a portion of the over-ground stem; inner or cut surface somewhat concave, the edges in-curved with the overlapping bark, yellowish brown to grayish brown, longitudinally striate and more or less fibrous near the cambium zone; fracture short and horny; internally light brown and marked by numerous circular or elliptical oleoresin canals; roots cylindrical and tapering, frequently curved or irregularly curled, up to 13 cm. in length and 1.5 cm. in diameter. Odor aromatic; taste acrid, bitter and pungent.

"*Structure.*—A corky layer of from 4 to 7 rows of broad tabular cells; a cortex of numerous parenchyma cells containing inulin in irregular or fan-shaped masses and a number of large, intercellular secretion cavities containing oleoresin, arranged in nearly radial rows and forming interrupted circles; woody portion consisting chiefly of parenchyma, a number of tracheæ with simple pores or reticulate thickenings and associated occasionally with a few, strongly lignified wood fibers, and secretion cavities containing oleoresin similar to those occurring in the bark; parenchyma cells in the pith of the rhizome large, containing less inulin than the cells of the wood and bark and separated by large intercellular spaces.

"*Powdered Inula.*—Light brown; consisting chiefly of fragments of parenchyma containing inulin and small, irregular, separated masses of inulin; tracheæ with simple pores and reticulate thickenings associated occasionally with strongly lignified wood fibers; occasional reddish brown fragments of the walls of the oleoresin canals." *N. F.*

Constituents.—In 1804 Rose found in this root a peculiar carbohydrate which he called *alantin* which is now, however, generally known as *inulin* and which has since been found in many other plants. It differs from starch in that it is not decomposed by boiling water, and gives a yellowish instead of a blue color with iodin. Tanret has also found two related principles that he called *pseudo-inulin* and *inulenin*. According to Dragendorff the amount of inulin in the root gathered in the spring is about 19 per cent. but in the fall approaches 45 per cent. When distilled with water elecampane yields from 1 to 2 per cent. of a crystalline substance mixed with volatile oil. The crystalline portion known as *alant-camphor* appears to be a mixture of *alanto-lactone* (the anhydride of *alantic acid*) $C_{15}H_{20}O_2$, and isoalanto-lactone (*helenin*) C_6H_8O. The oily portion which has a peppermint-like odor is composed chiefly of *alantol,* $C_{10}H_{16}O$ (see Kallen, *B. Chem. G.*, 1873 and 1876).

Korab (*L. L.*, 1885, i, 672) states that helenin is a powerful antiseptic and bactericide, one part in ten thousand being sufficient to kill the ordinary bacteria. He lauds it as antiseptic in surgery and has given it with alleged success internally in *doses* of one-third to one grain (0.021–0.065 Gm.) in tubercular and catarrhal *diarrheas.* It is also stated by J. B. Obiol (*L. L.*, April, 1886) to be an efficient local remedy in the treatment of *diphtheria.* Bockenham (*Th. M.*, 1892, p. 145) asserts that helenin inhibits the growth of tubercle bacilli in the dilution of 1 in 10,000 and it has been employed by various writers in the treatment of *pulmonary tuberculosis* in *doses* of from one-sixth to five grains (0.01–0.32 Gm.).

Elecampane is tonic and gently stimulant, and was employed by the ancients in *amenorrhea* and diseases of women, also in *phthisis,* in various bronchial catarrhs, and in *skin affections,* in all of which diseases it was probably of no service.

Dose, twenty grains to one drachm (1.3–3.9 Gm.).

Off. Prep.—Pilula Antiperiodica, *N. F.;* Pilula Antiperiodica sine Aloe, *N. F.;* Tinctura Antiperiodica, *N. F.;* Tinctura Antiperiodica sine Aloe, *N. F.*

IODOFORMUM. U. S., Br.

IODOFORM Iodof.

"Triiodomethane [CHI_3]." *U. S.* "Iodoform, CHI_3, may be obtained in the action of iodine on ethylic alcohol in the presence of solution of potassium carbonate." *Br.*

Triiodomethane, Formyltriiodide; Iodoforme, *Fr. Cod.* Iodure de formyle, *Fr.;* Jodoformium, *P. G.;* Jodoform, Carboneum jodatum, Trijodmethan, *G.;* Jodoformio, Trijodometano, *It.;* Yodoformo, *Sp.*

This compound, discovered by Sérullas about 1828, was later investigated chemically by J. B. Dumas. It was introduced as a remedy, about the year 1837, by R. M. Glover of London, and Bouchardat, of Paris, and was first adopted as official in the U. S. Pharmacopœia of 1870.

Various methods for the manufacture of iodoform by various processes that depend upon the interaction of iodine, alcohol, or acetone in the presence of an alkali or alkaline carbonate have been suggested. (See *U. S. D.,* 19th edition, p. 659.)

Iodoform is now made by electrolysis. An alkaline solution of sodium iodide is electrolyzed in the presence of alcohol; from the iodine which is liberated at the anode, iodoform is obtained by the following reaction:

$$CH_3.CH_2OH + 10I + H_2O = CHI_3 + CO_2 + 7HI$$

The hydriodic acid formed combines with the sodium hydroxide present, to make sodium iodate, which, with the carbon dioxide, forms the side products. The temperature is kept at about 70° C. during the reaction and a diaphragm is used. The yield of iodoform is about 70 per cent. M. Otto produces iodoform industrially, direct from alkaline iodides, as follows: 100 kg. of water, 300 kg. of alcohol, 10 kg. of sodium carbonate and 55 kg. of potassium iodide are heated to 50° C. in a suitable vessel, and a current of ozone is passed through the mixture. Iodoform is deposited and crystallizes in a pure condition on the sides of the vessel and throughout the fluid itself. The alcohol may be replaced by acetaldehyde, acetone, etc. (*Ap. Ztg.,* 1900, 166.)

The fact, noticed by Lieben in 1870, that many other compounds besides ethyl alcohol yield iodoform when treated with iodine and alkali, led Krämer (*B. Chem. G.,* 1880, p. 1000) to propose the iodoform formation as an exact quantitative test for the presence of acetone in methyl alcohol. This "iodoform test" is now used in testing the purity of methyl alcohol for use in the manufacture of aniline dye colors, as well as the purity of acetone itself. It is also used as a confirmatory test for the identification of ethyl alcohol in the absence of acetone or aldehyde. (See *Acetonum.*)

Description and Physical Properties.—"A fine lemon-yellow powder, or lustrous crystals. It has a peculiar, very penetrating, persistent odor. Iodoform is practically insoluble in water to which, however, it imparts its odor and taste. One Gm. of Iodoform is soluble in 60 cc. of alcohol, 80 cc. of glycerin, 10 cc. of chloroform, 7.5 cc. of ether, 2.8 cc. of carbon disulphide, and in 34 cc. of olive oil, at 25° C. One Gm. is soluble in about 16 cc. of boiling alcohol. Iodoform is slightly volatile even at ordinary temperatures, and distils slowly with the vapor of water.

"At about 115° C. it melts to a brown liquid, and at a higher temperature decomposes, emitting vapors of iodine. Its solutions are neutral to litmus paper. Ash: not more than 0.2 per cent. On drying 1 Gm. of Iodoform over sulphuric acid for twenty-four hours, it loses not more than 1 per cent. Shake about 2 Gm. of Iodoform with 5 cc. of distilled water for one minute, and filter: the filtrate is colorless and free from bitter taste (*soluble yellow coloring matter*), and does not affect the color of litmus paper (*acids or alkalies*).

"Preserve in well-closed containers, in a cool place, protected from light." *U. S.*

"Shining, lemon-yellow, small, hexagonal crystals, somewhat unctuous to the touch. Odor and taste persistent and disagreeable. Very slightly soluble in *water;* soluble in 100 parts of *alcohol* (90 per cent.), and in 8 parts of *ether,* the solutions being neutral to *litmus;* soluble also in *chloroform,* in *carbon disulphide,* in volatile oils, and in fixed oils; sparingly soluble in *benzene.* When warmed with *alcoholic solution of potassium hydroxide,* the resulting solution, acidified with *nitric acid,* becomes brown, and, when cold, changes to blue on the addition of *mucilage of starch.* 10 millilitres of *water* with which 1 gramme of Iodoform has been shaken are colorless and not bitter (absence of soluble yellow coloring matters and of picric acid), and yield no *reactions* for iodides. No appreciable ash." *Br.*

Iodoform is a volatile substance, soft to the touch, and totally devoid of corrosive properties. With potassium hydroxide in solution, it is decomposed, yielding potassium formate and iodide. Hence these two principles are incompatible in prescriptions. The specific gravity of iodoform, about which there has been a controversy, was determined by J. Percy Remington to be 4.000; the specific gravity of 2.000, as given in the U. S. P. 1890, was undoubtedly due to the operator taking the specific gravity of iodoform in water, and when this is done it is practically impossible to free the crystals from admixed air; the result was reached by using a saturated solution of iodoform in pure kerosene as the liquid, and by a simple calculation obtaining the equivalent in water. Iodoform is sometimes met with in commerce adulterated with water; Vulpius (*Ph. Cb.*, 1894) on examination detected 13 per cent. in one specimen.

Uses.—When applied to a mucous membrane, iodoform exercises a marked anesthetic action. Although of itself it is almost free of antibacterial properties, when brought in contact with the bodily secretions it gradually liberates some compound—perhaps free iodine—which is actively antiseptic. The experiments of Gosselin of Caen indicate that it is especially inimical to the tubercle bacillus. If taken internally it is gradually absorbed and is partially decomposed, liberating inorganic iodine; a part, however, appears to circulate unchanged. When exhibited in large doses, to the lower animals, it produces narcotic effects, and two stages in its operation have been noticed; the first is marked with more or less prostration, with symptoms of intoxication, the animal tottering, inclining to one side with the head falling, with loss of appetite, but without vomiting. The next day, unless a very large dose has been given complete recovery takes place. A still larger dose induces the second stage, characterized by a remarkably intense excitation, with anxious breathing, strong and short pulse, a true opisthotonos, sometimes very striking, and convulsive movements of the paws, especially the hinder ones. After death fatty degeneration of the heart, liver, and kidneys may be found.

The chief value of iodoform in practical medicine is as an external application. It has long been used in cases of painful *ulcers* and as an antiseptic dressing to *wounds.* The testimony from surgeons is so strong that it is difficult to avoid believing that it is one of the most certain remedies of the class. Its beneficial effects seem to be due partly to absorption of secretions—making an unfavorable soil for bacterial growth—partly to the antiseptic effect of its decomposition products and partly to its local anesthetic effect. Some believe that it exerts some specific influence on cell growth that encourages healing. It is also of much value for its anesthetic powers in *laryngeal tuberculosis* and in *internal hemorrhoids;* in the latter condition it is best applied in the form of a suppository, which may contain from five to ten grains (0.3–0.6 Gm.).

The local application of iodoform in surgical *tuberculosis* has received the highest commendation from numerous surgeons. In the treatment of *tuberculous abscesses,* in tuberculous *empyema,* in *tubercular joints,* in non-suppurating *tuberculous glands,* and even in *tuberculous peritonitis,* numerous cures have been claimed. The manner of application varies with different surgeons. Verneuil, who has had an enormous experience, prefers in the treatment of abscesses and of tuberculous glands, and in most other cases, the injection of a 5 per cent. ether solution. Others prefer glycerin as a vehicle, especially in empyema cases, while others, especially in *peritonitis,* dust the dry powder over the surface which has been laid open.

Internally, iodoform has been used in *syphilis, goiter,* and *phthisis,* originally with the idea that it would act as an iodide. As pointed out above, however, it is only partly broken up in the system and its action therefore is quite different from the inorganic iodides. Whether it is of any real value as internal remedy is at present open to doubt.

Iodoform gauze may be made by saturating surgical gauze with a 5 per cent. solution of iodoform in ether, and allowing it to dry at room temperature.

One of the principal obstacles to its employment is the odor, which, to some patients, is unbearable. Many methods of disguising the odor have been recommended, but in our experience the large quantity required of each deodorizing agent would preclude its employment. Tannin has been recommended, but, as this operates by decomposing the iodoform, it is not to be thought of in this connection. Probably the best class of substances to use are the volatile oils, such as anise, peppermint, fennel, bergamot, almond, coumarin, etc. Balsam of Peru acts by forming a compound, and the aim should be not to destroy the odor, but so to modify it as to remove its objectionable features. Olive oil saturated with camphor is said to dissolve 6 per cent. of iodoform, and is preferred by some surgeons.

Toxicology.—The free use of iodoform as a surgical antiseptic has led to many cases of poisoning. In the most characteristic and severe cases the phenomena of iodoform poisoning resemble somewhat those of meningitis; they are headache, somnolence, deepening into stupor, contracted, motionless pupils, abnormal quiet or restlessness ending in active delirium, with, however, a normal temperature and an exceedingly rapid pulse. Burlureaux affirms that if a piece of silver be placed in the mouth of a person suffering from iodoform poisoning, immediately the taste of garlic will be perceived, and if some of the saliva be mixed with calomel, a canary-yellow precipitate of mercurial iodide will be obtained. The most that such a test can accomplish is to show that the patient is under the influence of some compound of iodine. In cases of this character death almost always follows, although the symptoms may have developed abruptly and the dressing has at once been removed. In other cases the principal symptoms are general malaise and depression, faintness, headache, loss of appetite, and a persistent iodoform taste in the mouth. In some cases there is a slight temporary increase of temperature. Mental depression or excitement is especially noticed. Finally the pulse becomes accelerated, soft, and feeble; in some cases the pulse is very rapid—from 150 to 180—while the temperature remains normal or is only slightly elevated. It is asserted by Samter and Retzlaff (*T. G.*, 1889) that potassium bromide is an antidote in iodoform poisoning, its antidotal powers being due to the fact that it exceeds all other salts in its power of dissolving iodine compounds.

Langenstein has attributed a fatal result to the local application of one drachm of the powder. It is advisable that in ordinary cases not more than thirty grains (2 Gm.) be employed at once as a wound dressing, although in cases of tuberculosis the surgeon is warranted in taking the risk of larger amounts. Verneuil sometimes injects at one sitting 75 grains of the iodoform.

Dose, one to five grains (0.065–0.32 Gm.).

IODINE

"Iodine contains not less than 99.5 per cent. of I." *U. S.* "Iodine may be obtained from the ashes of seaweeds and from native iodides and iodates. It contains not less than 99 per cent. of pure iodine, I." *Br.*

Iodinium, *U. S.* 1870; Iode sublimé, *Fr. Cod.;* Iode, *Fr.;* Jodum, *P. G.;* Jod, *G.;* Jodo, *It.;* Yodo, *Sp.*

Iodine is a non-metallic element, discovered in 1812 by Courtois, a soda manufacturer of Paris. It exists in certain marine algæ, particularly the kelps and rockweeds, which have long been its most abundant natural source. It has been reported in some fresh water plants, among which are the water cress, brooklime, and fine-leaved water hemlock; also in various terrestrial plants. Traces are present in the water of springs and rivers in many parts of the world. Iodine also occurs in the animal kingdom, as in the sponge, the oyster, crude cod liver oil, and the thyroid gland of mammals. It is found as silver iodide in a rare Mexican mineral, in a zinc ore of Silesia, in native sodium nitrate, and in some kinds of rock salt. It is now obtained commercially from native sodium nitrate, or Chili saltpeter, with which it occurs as sodium iodate. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by William Usher. It was detected in the Kanawha saline waters by Emmet, and it occurs in the bittern of the salt works of Western Pennsylvania, in the amount of about eight grains to the gallon. In sea weeds the iodine exists probably in the state of sodium iodide.

In different countries sea weeds are burned for the sake of their ashes, the product being a dark-colored fused mass called *kelp-varec* or *barilla* according to the locality where it is produced. This substance, besides sodium carbonate and iodide, contains more or less sodium chloride, potassium chloride, sodium sulphate, etc. The deep sea fuci contain the most iodine, and when these are burned at a low temperature for fuel, as is the case in the island of Guernsey, their ashes furnish more iodine than does ordinary kelp. (Graham.) According to Geo. Kemp, the laminarian species, especially *Laminaria digitata, L. saccharina,* and *L. bulbosa,* which are deep water sea weeds, and contain more potassium than sodium, are particularly rich in iodine.

In Japan the sea weeds most used are species of *Ecklonia* and *Sargassum* which contain about 0.14 per cent. iodine. In France certain species of *Fucus* are employed. These are collected by hand and dried by primitive methods. The dried weeds are burned in covered trenches. The ash sometimes contains over 5 per cent. of iodine but usually runs below 1 per cent. The iodine is recovered by the copper iodide method employed for separating it from Chili saltpeter as described below. On the California coast in America during the World War, sea weeds were largely used for destructive distillation for acetone, acetic acid, etc. The ash was used for the potassium salts and iodine.

All sea weeds do not contain enough iodine to make the industry profitable. Van Itallie has shown that *Zoster Marina* only contains 0.0019 per cent. of total iodine.

Iodine has been reported in waters of certain wells. In Java there is one which contains 120 parts of sodium iodide to the million. This has been recovered by the cuprous iodide method.

In Great Britain, chiefly at Glasgow, the ash of the kelp is lixiviated with water, in which about half dissolves. The solution is concentrated until a pellicle forms and allowed to cool, whereby nearly all the salts, except sodium iodide, are separated, they being less solube than the iodide. The remaining liquor, which is dense and dark-colored, is made very sour by sulphuric acid, which causes the evolution of carbon dioxide, hydrogen sulphide and sulphurous acid, and the deposition of sulphur. The amount of sulphur recovered in this way is more than 100 tons annually. The liquor is then introduced into a leaden still, and distilled with manganese dioxide into a series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the sodium iodide is decomposed, and the iodine evolved according to the reaction:

$$2NaI + 2H_2SO_4 + MnO_2 = MnSO_4 + Na_2SO_4 + 2H_2O + I_2$$

which leaves as residue manganous sulphate and sodium sulphate. In this treatment much care is needed to avoid the liberation of chlorine from chlorides present, which will form volatile iodine trichloride and so occasion loss. This can be avoided by heating the acidified iodide solution with ferric chloride, when iodine is liberated according to the reaction:

$$2NaI + 2FeCl_3 = 2FeCl_2 + 2NaCl + I_2$$

The methods for the separation of the iodine from its combinations in the mother liquors as practised in South America may be divided essentially into three classes. (1) The mother liquors after the crystallization of the saltpeter without further concentration are treated with a solution of sodium sulphite of strength exactly corresponding to the amount of iodine present, for if an excess be used the iodine will be converted into hydriodic acid; the iodine is liberated according to the reaction:

$$2NaIO_3 + 4HNaSO_3 + SO_2 = Na_2SO_4 + 4HNaSO_4 + I_2$$

the iodine thus separated from the sodium iodate is filtered through linen cloth, washed, pressed, and sublimed. (2) The mother liquors are treated with sodium sulphite or bisulphite until the precipitated iodine is converted into HI, and this is precipitated as cuprous iodide by a solution of copper sulphate and sodium sulphite. (3) The concentration of iodine is increased by fractional evaporation and crystallization of the mother liquors, and then, after adding the calculated amount of sodium bisulphite, the iodine is distilled off from the acidified liquor.

The methods formerly practised for obtaining iodine from sea weeds were accompanied with great loss. A notable improvement over the old kelp processes are the "char" and "wet" processes of E. C. C. Stanford (*J. Soc. Chem. Ind.*, 1885, p. 518).

Iodine is purified by sublimation in containers of porcelain, earthenware or glass, taking care to reject any white crystals which may appear in the first portion which comes over, as these consist of cyanogen iodide. Moisture which has sometimes been reported to the extent of 15 or 20 per cent. and which may be suspected if the iodine adheres to the inside of the container in which it is kept, may be readily detected by assaying for the iodine content and also by the fact that such iodine will not make a transparent solution with chloroform.

Description and Physical Properties.—"Heavy, bluish-black, brittle, rhombic plates, having a metallic luster and a distinctive odor. One Gm. of Iodine is soluble in 2950 cc. of water, 12.5 cc. of alcohol, 80 cc. of glycerin, and in 4 cc. of carbon disulphide, at 25° C. It is freely soluble in chloroform, carbon tetrachloride, and in ether, and is dissolved by aqueous solutions of iodides. Its solution in alcohol and in an aqueous solution of potassium iodide has a reddish-brown color. Its solution (1 in 1000) in chloroform, carbon tetrachloride, and in carbon disulphide is of a violet color.

"Specific gravity: about 4.66 at 17° C. Iodine imparts a deep brown, evanescent stain to the skin and slowly destroys vegetable colors. Iodine volatilizes slowly at ordinary temperatures. When heated to about 114° C., it fuses and gradually vaporizes in the form of violet fumes. Add starch T.S. to a saturated aqueous solution of Iodine: a blue color is produced. On boiling the mixture the color vanishes but reappears as it cools, unless it has been subjected to long continued boiling.

"When volatilized, Iodine leaves not more than 0.05 per cent. of residue. Triturate 0.5 Gm. of finely powdered Iodine with 20 cc. of distilled water, and filter the solution. To one-half of the filtrate carefully add tenth-normal sodium thiosulphate until the solution is just decolorized. Then add a few drops of ferrous sulphate T.S. and subsequently a little sodium hydroxide T.S., and heat the mixture gently: the liquid does not become blue upon the addition of a slight excess of hydrochloric acid (*cyanogen*). To the other half of the aqueous filtrate, add, drop by drop, sulphurous acid (free from chloride), previously diluted with several volumes of distilled water, until the iodine color just disappears. Add 5 cc. of ammonia T.S., and follow with 5 cc. of silver nitrate T.S. in small portions. Filter, and acidulate the filtrate with nitric acid: the resulting turbidity is not greater than that produced in a control test made with the same quantities of reagents to which 0.1 cc. of fiftieth-normal hydrochloric acid has been added, but omitting the sulphurous acid (*chloride or bromide*).

"**Assay.**—Place about 0.5 Gm. of powdered Iodine in a tared weighing-bottle, stopper, weigh accurately, and add 1 Gm. of potassium iodide dissolved in 5 cc. of distilled water. Dilute this solution with distilled water to about 50 cc., and titrate with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01269 Gm. of I.

"Preserve in glass-stoppered bottles, in a cool place." *U. S.*

"In rhombic prisms or octahedrons of the trimetric system, of dark color, and metallic lustre. Characteristic odor. Yields, when gently heated, a violet-colored vapor. Very slightly soluble in *water*, more soluble in *alcohol* (90 per cent.); readily soluble in *solution of potassium iodide*, in *ether*, and in *carbon disulphide*. *Mucilage of starch* colors the aqueous solution deep blue. Sublimes without appreciable residue, the first portion sublimed not including any slender colorless prisms emitting a pungent odor (absence of iodine cyanide). A solution of Iodine in *chloroform* is perfectly clear (absence of moisture). 0.5 gramme, dissolved in 50 millilitres of *water* containing 1 gramme of *potassium iodide*, requires for decolorisation not less than 39 millilitres of *N/10 solution of sodium thiosulphate*." *Br.*

In chemical characters iodine resembles chlorine, but its affinities are weaker. It combines with most of the non-metallic and nearly all the metallic elements, forming a class of compounds called iodides. Some of these are official, as the iron, mercury, lead, potassium and sodium iodides. It forms with oxygen one oxide, *iodic oxide*, I_2O_5, and two acids, *iodic* and *periodic*, and with hydrogen an acid called *hydriodic acid* which is official as the diluted acid and in the syrup.

Tests.—Iodine, in most cases, may be recognized by its characteristic purple vapor; but, where this cannot be made evident it is detected by starch, which produces with it a deep-blue color. Bargu and Starling (*P. J.*, 1914, xcii, 146) have called attention to the fact that other organic compounds besides starch have the property of showing a blue color with iodine, and have published a list of more than sixty such substances.

The detection and estimation of iodine in small amounts in combinations containing organic matter may be accomplished by methods analogous to the one used for the estimation of iodine in thyroid glands, which see.

One of the most delicate reactions yet devised for the qualitative detection of iodine is that discovered by Ciusa and Terni (*Gaz. Ch. It.*, 43, ii, 86) in which a solution composed of 10 grammes of mercuric nitrate, 50 cc. of distilled water, 5 cc. of nitric acid, and 60 cc. of stronger ammonia water, is used. One cc. of the reagent is added to 25 cc. of the solution to be tested, chlorides give a white precipitate and bromides a yellow precipitate, neither of which are distinctive or interfere in any way. If iodides are present even in minute amounts an orange or brownish color or precipitate is produced.

It has been long known that when a mixture of iodine and starch in water is subjected to heat the blue color disappears, and that, if the heat be not too long continued, so as to volatilize the iodine or convert it into hydriodic acid, the color will return on the cooling of the liquid. Various explanations have been given of this curious fact by Personne and others none of which is entirely satisfactory.

Iodine was at one time occasionally adulterated with mineral coal, charcoal, plumbago, and black manganese oxide. These were easily detected by their fixed nature, while pure iodine is wholly volatilized by heat. Such adulterations have long since been discontinued.

Uses.—Iodine was first employed as a medicine in 1819, by Coindet, of Geneva. Iodine, whether taken into the stomach in the form of the element or as one of the salts of hydriodic acid, is absorbed readily and circulates in the blood chiefly in the form of an iodide, although it is probable that a small amount of the iodine is absorbed in the form of a protein compound. Although it can be found in a number of other secretions it is eliminated practically entirely through the kidneys. Herzfeld and Elin (*B. M. J.*, October 5, 1912) state that iodine can be demonstrated in the urine after painting the skin with the tincture, but Wetzel and Sollmann reached the conclusion that appreciable amounts could not be absorbed through the skin either from the tincture or ointment. As iodine circulates as an iodide the effects are the same whether it be given in the elemental state or as a salt of hydriodic acid. Although Macht (*J. H. H. B.*, 1914, xxv) states that the iodine ion is a powerful stimulant when perfused through isolated heart or blood vessels, when introduced into the circulation of the intact mammal it has practically no influence. The common belief that the iodides dilate the arterioles is absolutely without reasonable foundation. (See Capps, *J. A. M. A.*, 1912, lix, 1350.) The only important physiological effect of iodine is its influence upon metabolism. This action is not clearly understood although it is evident that the continued use of this drug increases the rapidity of nitrogenous breakdown; according to Chistoni (*A. I. P. T.*, xxi, p. 339), the elimination of uric acid and other purin bases is increased disproportionately. Grabfield and Prentiss (*J. P. Ex. T.*, 1925, xxv, 411) find that the iodides cause a marked increase of nitrogen in the urine which they interpret to mean an increased katabolism. There were differences in the effects of the various salts. It appears to have some influence upon glands—beyond its action as a salt—not only increasing the quantity but changing the character of their secretions, especially diminishing excessive viscidity. In those morbid states attended with fibrinous exudation, the iodides have a similar effect on the exudate. There is a belief among many practitioners that it will even cause the absorption of organized fibroid tissue; this, however, is not well substantiated. In *syphilis* and *tuberculosis* there is often a very rapid breaking down of the characteristic local lesions. This effect seems to be due to an increased autolysis but whether a specific reaction in certain diseases or merely the manifestations of general effect in the *locum minoris resistentiæ* is uncertain.

In *syphilis* iodine is without a direct curative property, that is, it has no effect upon the growth of the specific micro-organism. Because, however, of its power of causing the breakdown of syphilitic lesions it is a remedy of utmost importance in the tertiary stage, not merely because it lessens the extent of the sequelæ of the luetic affection, but because it drives the spirochetes from their lurking places into the general circulation where they may be reached by direct antisyphilitics. In the early stages iodine is useful because it forms a freely soluble compound with the mercury and thereby tends to prevent the deposit of the metal in internal organs.

Its effect in tuberculosis is analogous to that in *syphilis*, but whether this action in hastening the breakdown of the lesions will be beneficial or otherwise to the tuberculous patient, depends upon the location and character of the infection. Thus in *phthisis* generally the most favorable result is the walling off and ultimate calcification of the local lesion and the iodides by softening the infected area may not only delay the whole process, but may even cause a dissemination of the micro-organisms throughout the lung. On the other hand, in inoperable *lymphadenitis* it will hasten suppuration and may lead to the extrusion of the bacilli. In a somewhat similar way iodine may be useful in *bony tuberculosis.*

In *leprosy* it apparently has a somewhat similar type of action, although less marked. It has also a potent effect in *actinomycosis* and even appears to have a direct curative effect. In inflammations of either the serous or mucous membranes attended with fibrinous exudates or viscid secretions, as *pleurisy, pericarditis,* or *bronchitis,* iodine is often of great value because of its liquefying action. In *bronchitic asthma,* while it has no direct influence upon the paroxysms, by its effect in increasing and liquefying the bronchial secretions it proves itself one of the most frequently serviceable drugs we possess. In chronic inflammatory conditions accompanied with a formation of fibroid connective tissue, as in *interstitial nephritis, arteriosclerosis,* and fibroid degenerations of the nervous centers, it is widely employed, not, however, because it is of proven utility but in a kind of despairing hope that it may produce some amelioration of the condition. In degenerative changes occurring as the result of *syphilis,* however, such as *locomotor ataxia,* it often appears to have some beneficial effect. It is habitually employed in *chronic rheumatism* which it probably influences through its action upon metabolism. It has long been known that iodine is a normal constituent of the thyroid gland. The present evidence is very strong that a supply of iodine is essential for the proper function of this gland. The studies of Marine and Kimball (*J. A. M. A.,* 1920, lxxv, 674) have shown that the exhibition of small amounts of iodides will prevent the occurrence of the simple *goiter* which is endemic in certain districts. The experiments of Reid Hunt (*J. P. Ex. T.,* 1910, ii, 15) suggest that large amounts of iodine excite the functional activity of the thyroid, and various authors have therefore held it to be contra-indicated in the so-called *exophthalmic goiter.* This view was vigorously attacked by Plummer (*J. A. M. A.,* 1923, lxxx, p. 1955) who recommended the use of massive doses of the tincture. Starr (*A. I. M.,* 1924, xxxiv, p. 355) reports that in 80 per cent. of cases of all types of Graves's disease iodine will cause a prompt, although in many instances only temporary, remission of symptoms. Potassium iodide forms in the body a freely soluble compound with either mercury or lead, and is therefore frequently used in the treatment of *lead poisoning* or in *mercurial* cachexia to hasten the elimination of the metal; it must be remembered, however, that by causing the solution of deposits it may cause an exacerbation of symptoms.

Elemental iodine has two important therapeutic properties which its salts do not share. These are as a local irritant and as a germicide. As a counter-irritant it is used especially in various forms of *arthritis,* notably those due to trauma, but is also of service in *bronchitis* or *glandular enlargement.* Its action in these conditions may be aided by absorption through the skin and consequent systemic effects of the drug. It is also employed for its local irritant effect as an injection for the cure of local effusions, as *ovarian dropsy, hydrocele,* and *ganglion.*

ANTISEPTIC USES.—Elemental iodine is a powerful germicide. A one to 1000 solution is sufficient to kill most vegetative forms of bacteria including the staphylococci, tubercle bacillus and the typhoid bacillus (Peck, *P. J.,* 1911, lxxxvii, 450). Maben and White (*C. D.,* 1915, 144) give it a phenol coefficient of 4. There are two qualities which have rendered it of peculiar value as a surgical disinfectant. In the studies of Lambert (*J. Ex. M.,* December, 1916), which were made with human connective tissue cells on artificial culture media, iodine was the only one of the germicides tested that would kill bacteria in strengths that were not injurious to the tissue cells. The second valuable property is its power of penetrating the skin. Turner and Catto (*L. L.,* 1911) found that after the external application of a 3 per cent. solution of iodine the whole thickness of the skin was sterile. Bovee (*Am. J. Obstetrics,* July, 1911) found that the application of 5 per cent. of the U. S. P. tincture of iodine completely sterilized the surface of the skin within 15 minutes but that hairy regions, as the pubes, required 50 per cent. of this tincture (representing 3 per cent. of iodine) for complete sterilization.

In 1908 Grossich (*Cb. Chir.,* 1908, p. 1285) suggested painting of the skin with a 10 per cent. tincture of iodine as a means of sterilizing the site of operation. According to his claims no previous washing was necessary because of the penetrating power of the iodine. The method has been widely followed and with more or less modification is now almost universally employed by surgeons. Probably the most commonly employed routine in this country is to cleanse the skin with liniment of soft soap, thoroughly wash away the soap with alcohol, and then paint with the official tincture of iodine. Among the various solutions which have been suggested instead of the tincture, probably the most widely employed is that in benzin originally suggested by Heussner. This author used a solution containing one part of iodine, 750 of benzin, and 250 of liquid petrolatum. Reich-Brutzkus (*W. K. W.,* 1913) uses a solution containing 3 parts of iodine, 10 parts of alcohol, and 90 of chloroform. From its use in sterilizing the seat of operation iodine has rapidly come into popularity as a surgical disinfectant for a wide variety of purposes. Woodbury (*N. Y. M. J.,* 1912, xcvi, p. 101) recommends it to sterilize the surgeon's hands, instruments, sutures, and dressings. The application of a 3 per cent. solution of iodine to recent wounds is probably the most efficient emergency treatment we have to protect against infection by the pus producing organisms. A number of authors have attributed most brilliant results in *erysipelas* to painting the affected part with tincture of iodine. (See Lammerhirt, *B. K. W.,* 1921, lviii, 1389.) In proper dilutions it is used in various infections of mucous membranes as *conjunctivitis, urethritis, diphtheria, cystitis,* etc. More recently the vapors of nascent iodine have been employed in various local infections. These may be generated by heating iodoform. It is also used locally in various skin diseases both for its antiseptic and alterative effect.

Méhu's method of making *iodized cotton* is as follows: Finely divided iodine (5 to 10 parts) is sprinkled between layers of loose cotton (100 parts) introduced into a tall glass vessel, and the latter placed horizontally on a water or sand bath. As soon as vapors of iodine are seen to rise, and the air has been expelled from the vessel, the latter is tightly stoppered. On continuing to apply a moderate and uniform heat, the iodine vapors penetrate the cotton, and color it yellow. After about two hours, the cotton will have assumed the color of burnt coffee, and the operation is finished. Cotton iodized in other ways, as by immersion in concentrated solutions of iodine in ether or carbon disulphide, retains merely traces of iodine. (*N. R.*, April, 1867.)

Iodine, in the state of vapor, has been employed by inhalation, in the treatment of *phthisis* and *chronic bronchitis,* but has failed to fulfil expectations, and is at present very rarely practised. For details as to methods, the reader is referred to the 14th edition of the *U. S. D.*

Under the names of *iodagol* and *iodéol* suspensions asserted to contain 25 per cent. and 20 per cent., respectively, of *colloidal iodine* have been introduced for local applications.

As an internal remedy one of the salts of hydriodic acid is usually preferred as being less prone to disturb digestion although the compound solution is frequently of service. Although less irritant than iodine the iodides are still very prone to upset the stomach. This fact has led to the official recognition of calioben, and the preparation of a host of compounds many of which are noticed in Part II of this work.

In an overdose elemental iodine acts as an irritant poison. From four to six grains (0.26–0.4 Gm.), in man, cause a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. Even in medicinal doses it sometimes causes alarming symptoms such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse, and, finally, progressive emaciation if the medicine be not discontinued. Such violent symptoms are, however, very rare, but where iodine or potassium iodide is given freely a mild *iodism* is not unfrequent. It is usually characterized by pain or heaviness in the region of the frontal sinuses, with or without coryza; in some instances soreness of the mucous membrane of the mouth and throat, or a mild ptyalism, is the prominent symptom, or a papular eruption may be the first manifestation of the constitutional action of the remedy. Various skin lesions of all degrees of severity have followed the internal use of iodides in sensitive persons. Absorption of the mammæ and wasting of the testicles have been reported as caused by the long-continued use of the drug, but such results are extremely rare.

In cases of acute poisoning by iodine, the stomach must be evacuated, and drinks administered containing an amylaceous substance, such as flour, starch, or arrow-root.

Dose, of iodine, one-twelfth to one grain (0.005–0.065 Gm.) well diluted.

IPECACUANHA. U. S. (Br.)

IPECAC Ipecac. [Ipecacuanhæ radix P. I.]

"Ipecac is the dried rhizome and root of *Cephaelis Ipecacuanha* (Brotero) A. Richard, known in commerce as Rio Ipecac (Brazilian Ipecac), or of *Cephaelis acuminata* Karsten, known in commerce as Cartagena or Panama Ipecac (Fam. *Rubiaceæ*).

"Ipecac yields not less than 1.75 per cent. of the ether-soluble alkaloids of Ipecac and contains not more than 5 per cent. of its overground stems, or more than 2 per cent. of other foreign organic matter." *U. S.* "Ipecacuanha Root is the dried root of Psychotria Ipecacuanha, *Stokes.*" *Br.*

Ipecacuanhæ Radix, *Br.;* Ipecacuanha Root; Poaya, *Braz.;* Ipécacuanha annelé, *Fr. Cod.;* Racine brésilienne, *Fr.;* Radix Ipecacuanhæ, *P. G.;* Ruhrwurzel, Brechwurzel, Ipecacuanha, *G.;* Ipecacuana, *It.;* Ipecacuana (Raiz de), *Sp.*

Ipecac has been official in every edition of the U. S. P. since 1820. Martius in his *Flora Brasiliensis* states that the South American aborigines were acquainted with the medicinal properties of the plant and Purchas, in *The Pilgrimes,* published in London in 1625, cites a description of Brazilian ipecac, believed to have been written by M. Tristaon, in which its uses by the Indians are discussed. Piso and Marcgraf, in *Historia Naturalis Braziliæ* (Amsterdam, 1648) give a good account of a brown and a white ipecac, the illustration of the brown variety closely agreeing with the true ipecac, according to Merat (*Dict. Univ. de Mat. Méd.,* Paris, 1846). The root was first introduced as a drug into Europe by Le Gras in 1672, but did not begin to become popular there until toward the close of the eighteenth century.

The term *"ipecacuanha"* had been applied by the aborigines of Brazil to various roots having emetic properties and, as the use of ipecac in Europe began to call for larger importations, many other emetic roots from South America were substituted for it. In this way the characteristics of the plant furnishing the genuine article became almost forgotten and earlier diagnoses by botanists were frequently based upon plant materials other than the genuine ipecac. No less an authority than Linnæus thought the plant now known as *Ionidium Ipecacuanha* St. Hil. to be the source of true ipecac and named it *Viola Ipecacuanha.* In 1781, Linnæus filius, believing the illustration by Piso of the true ipecac plant to be identical with a Peruvian emetic plant sent him with a description by Mutis, named it *Psychotria emetica.* Dr. Gomez collected some authentic plants in Brazil in 1800, corrected this error in his memoir published in Lisbon the following year and re-established the nearly forgotten characteristics of the true botanical source. He gave some of his specimens to Brotero who describes the species under the name of *Callicocca Ipecacuanha* in the *Transactions of the Linnean Society,* 1802. In 1813, Tussac renamed the same species which Brotero described, *Cephaelis Ipecacuanha* and distinguished it from *Psychotria emetica* Mutis. Achille Richard, in his *Natural and Medical History of Different Ipecac Species of Commerce* (Paris, 1820), again mentioned the differences between these two species. While Tussac preceded Richard in placing the authentic plant in the genus *Cephaelis,* his work did not become as well known as that of Richard and so some systematists give the credit of authorship to Richard.

There exists considerable difference of opinion as to which of the generic terms should be definitely adopted as the standardized generic name of the true ipecac species. Chief among those listed in the literature as synonyms are the following: *Uragoga,* L. 1731, *Psychotria,* L. 1759, *Evea,* Aublet 1775, *Tapogomea,* Aublet 1775, *Cephaelis,* Swartz 1788, and *Callicocca,* Schreber 1789. According to the rule of priority in starting nomenclature with 1753, *Uragoga* would be correct as the proper designation of the Ipecac genus and *Uragoga Ipecacuanha* Baillon (*Nat. Hist. Pl.,* London, 1881) the proper designation of the species; but *Cephaelis* of Swartz is alone listed in the *Nomina Conservanda* of the last International Congress of Botanists, evidently because it had received the greatest publicity and use and is, accordingly, recognized in the U. S. P.

Cephaelis Ipecacuanha is a low, straggling shrub indigenous to Brazil but also found growing in Colombia where it flourishes in deep, moist humous soils of forests. Its underground portion consists of a somewhat branched root system, the root being annulated and wiry, and a submerged portion of the stem which has generally been gathered with the roots as the drug of commerce. The latter arches upward, becoming green and angular above ground and attaining a length of a foot or less. It bears a few opposite, petiolate, stipulate, obovate and entire leaves and heads of small, white flowers, the corollas of which are funnel-shaped. The fruits occur as clusters of dark purple berries, each containing two plano-convex seeds.

The U. S. P. recognizes two sorts of ipecac which it ascribes to different botanical species although Humboldt regarded the differences between the plants as merely geographic variations. The *Rio, or Brazilian, Ipecac* is from the *Cephælis Ipecacuanha.* It grows in moist, dense and shady woods in Brazil and Bolivia. It is said to be most abundant within the limits of the eighth and twenty-second degrees of south latitude. *Cartagena Ipecac* (also called *Savanilla* and *Panama Ipecac*) is from the *C. acuminata.* It grows in the moist forests of United States of Colombia. The roots are gathered from January to late March by the natives who seize all the stems of a clump, loosen them from the soil and then, by thrusting a pointed stick under the roots, tear up the whole mass. The roots are then freed from adhering soil and packed in bags or bales of hide in which they are stored until purchased by traders; Rio Ipecac comes chiefly from the interior provinces of Matto-Grosso and Minas Geraes and is shipped to the U. S. A. mainly from Rio de Janeiro, Bahia and Pernambuco. Cartagena Ipecac is exported to this country from Cartagena and Savanilla, Colombia. It differs from the Rio variety in being thicker, grayish-brown or gray, and in showing less pronounced annulations.

Attempts have been made by the British in 1866 and 1872 to cultivate ipecac in India from root cuttings sent from Brazil but without commercial success. In 1886, it was found that ipecac flourished in the Straits Settlements. The *Johore,* or *Indian, Ipecac* is obtained there. Some success has recently been attained in growing the plant in the State of Selangor, near Singapore, from which considerable roots have been shipped to England.

Substitutes and Adulterants.—The chief adulterant of ipecac is the aerial stem of the same plant. The submerged portion of the stem from which roots emanate and which might be called the rhizome has been asserted by Viehoever and Ewing (*J. A. Ph. A.,* 1921, p. 766) to contain the ether-soluble alkaloids of ipecac in substantial amounts. The rhizome, which is now recognized in the official description must not be confused with an aerial continuation of it, the overground stems, which is comparatively inferior in alkaloidal content. The latter may be distinguished from the rhizome by its thinner bark, numerous chloroplasts, and by opposite leaf scars in its terminal portion.

Undulated Ipecac.—This is the root of *Richardsonia scabra* St. Hilaire (Fam. *Rubiaceæ*), indigenous to Brazil. It occurs in somewhat tortuous pieces which differ from ipecac in being less completely and regularly annulated and in possessing a porous wood and a bark that is often violet-colored within.

Greater Striated Ipecac.—The root of *Psychotria emetica* L. (Fam. *Rubiaceæ*) closely resembles the Cartagena Ipecac from which it can be distinguished by its violet-colored bark and total absence of starch, as viewed in transverse sections under a microscope.

Trinidad Ipecac.—The rhizomes and roots of *Asclepias curassavica* L. (Fam. *Asclepiadaceæ*) have been offered as a substitute in Europe. This spurious article is entirely devoid of ipecac alkaloids, has a yellowish-brown external color, a white interior and a bitter taste.

Lesser Striated Ipecac (Planchon). *Ipecac des Côtes d'Or* (Pelletier), *Black Ipecac. Black Striated Ipecac. Striated Brittle Ipecac* (Attfield). *False Ipecac* (Holmes).—This appears to be obtained from a species of *Richardsonia.* It occurs in very short fragments, 2 or 3 cm. long, and 2 or 3 mm. in thickness; some nearly cylindrical, others narrowly fusiform; others again formed of roundish or pyriform segments, somewhat thicker than the preceding, placed end to end. The color is generally of a gray-brown, darker than that of Greater Striated Ipecac. The longitudinal striæ are fine, and regular on the transverse section. The cortical portion starchy and often dark violet in color, and its consistence firmer than in the larger kind; the wood is yellowish, and porous.

White Ipecac is obtained from *Ionidium Ipecacuanha* St. Hil. (Fam. *Violaceæ*), indigenous to Brazil. The root is much branched, free from annulations and of a grayish-white or light brownish-yellow color. The bark is very thin and the wood is light-yellow and porous. It is distinguished by the presence of stone cells and freedom from starch. It contains inulin and no emetine. According to Pelletier, it has however, emetic properties.

In addition to the above the following adulterants have occasionally been found as admixtures of the drug: (1) The roots of *Heteropteris pauciflora* (Fam. *Malphigiaceæ*) which are devoid of starch and possess rosette aggregates of calcium oxalate and stone cells; (2) numerous other foreign roots. Kraemer (*Proc. A. Ph. A.*, 1900, p. 214) has published a note on a so-called ipecac which proved to be derived from *Polygala angulata* DC. The best work on the differentiation of ipecac is that of Hartwich. (*A. Pharm.*, 1904, p. 677; 1905, p. 647.) Tunmann (*Gehe and Co., Handelsbericht,* 1912, p. 165) has submitted this drug to pyroanalysis and obtained characteristic sublimate crystals. For elaborately illustrated articles upon the microscopy of ipecac and its adulterations, see Henry G. Greenish, *P. J.*, 1895, 685, and Albert Schneider, *Am. Drug.*, 1897. According to Greenish, the distinctive characteristics of the powder of either Brazilian or Cartagena ipecac are: (a) the form and size of the starch grains; (b) the absence of vessels, presence of perforated trachoides; (c) the acicular raphides; to these may be added (d) the emetine reaction with chlorine. The stem may in either case be distinguished from the root (in powder) by the presence (a) of sclerenchymatous cells; (b) of lignified cells of the pith; (c) of spiral vessels.

The root of a species of *Ionidium* growing in Quito has attracted some attention as a remedy in *elephantiasis,* under the South American name of *cuichunchulli.* The plant received from Bancroft the name of *I. Marcucci;* but Hooker found the specimen received from Bancroft to be the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *A. J. P.*, vii, 186.)

Description and Physical Properties.—"*Unground Rio Ipecac.*—Roots in cylindrical pieces, mostly curved and sharply flexuous, occasionally branched, from 3 to 15 cm. in lenth, from 1 to 4 mm. in thickness, reddish-brown to dark brown, either smooth or closely annulated, with thickened, incomplete rings and usually exhibiting transverse fissures with vertical sides; bark of smooth root thin, approximately one-ninth of the diameter of the root, that of the annulated root approximately two-thirds of the entire diameter; fracture of bark short, easily separable from the tough, fibrous wood; odor distinctive, the dust sternutatory; taste bitter, nauseous and acrid. Rhizomes cylindrical, attaining a length of 10 cm. and a thickness of 2 mm., finely longitudinally wrinkled, with a few elliptical scars and a distinct pith approximately one-sixth of the entire diameter.

"*Structure of Rio Ipecac.*—Outer layer dark brown, consisting of several layers of cork cells, some showing distinct granular masses covering the tangential walls; cortex grayish-white, consisting chiefly of parenchyma cells filled with starch grains, a few containing raphides of calcium oxalate; wood, light yellow, consisting of tracheids with bordered or slit-like pores, modified medullary rays of prosenchymatic cells containing starch grains, the latter up to 0.01 mm. in diameter and a few lignified fibers with oblique slit-like pores and more or less attenuated ends.

"*Unground Cartagena Ipecac.*—As compared with Rio Ipecac, from 4 to 6.5 mm. in thickness; externally grayish-brown, annulations less numerous; single starch grains, in the average, larger in the medullary rays of the wood.

"*Powdered Ipecac.*—Light brown. Elements of identification: the cork cells; the starch grains single and up to 5- to 7-compound, the single grains up to 0.015 mm. in diameter (Rio Ipecac) and up to 0.020 mm. in diameter (Cartagena Ipecac); raphides of calcium oxalate up to 0.050 mm. in length and fragments of the porous tracheids." *U. S.*

"In somewhat tortuous pieces seldom more than fifteen centimetres long or six millimetres thick; from dark brick-red to very dark brown;

closely annulated externally, the annulations not taking the form of narrow ridges partially encircling the root (distinction from Cartagena ipecacuanha). Fracture short, the fractured surface exhibiting a thick greyish bark and small dense wood. Bark consisting of thin-walled parenchymatous cells, some containing slender raphides, but most filled with simple or compound starch grains, the simple seldom exceeding fifteen microns in length; wood consisting chiefly of tracheids and containing no vessels or typical medullary rays. In the powdered Root, thin-walled parenchymatous tissue, abundant simple or compound starch grains, the single grains seldom exceeding 15 microns in diameter, acicular calcium oxalate crystals, fragments of brown cork, lignified tracheids and wood-parenchyma; but not more than a very occasional vessel or strongly thickened sclerenchymatous cell. Slight odor; taste bitter. Ash not more than 5 per cent. Yields not less than 2 per cent. of alkaloids when tested by the following process." *Br.*

Cartagena ipecac is usually to be distinguished from the Brazilian by its lighter color and the fact that many of its roots are scarcely at all annulated, and some are even smooth. On the other hand, in most specimens of Cartagena ipecac which we have examined, some of the roots could not be distinguished from those of the Brazilian variety. The cultivation of ipecac, which was introduced into India by the British Government, has especially succeeded in the neighborhood of Johore (Straits Settlement). On account of the great local demands in India, only a small amount of this ipecac comes into general commerce, and very little of it reaches the United States. *Johore* or *Indian Ipecac* is especially characterized by the excellent appearance, regularity and large size of the roots, which are deeply annulated, somewhat light in color, and having to a marked degree the general physical and microscopical characteristics of the Brazilian root. Beilee asserts that the Indian Ipecac is usually inferior to the Brazilian, yielding only 0.54 per cent. of emetine (*Bull. Soc. de Pharm. de Bordeaux,* xlvi, p. 171), but according to Ransom, Paul and Cownley, and to Umney and Swinton, it is very rich in alkaloids, and, like the Brazilian root, has for its dominant alkaloid, emetine. Many years ago there was imported from Carácas into the United States a large gray ipecac with badly marked rings. This variety disappeared for a time but is probably the *Colombian* or *Cartagena Ipecac* of modern commerce. It is quite common to find in commerce mixtures of Rio and Cartagena Ipecac. These are usually distinguished from each other by the larger size of the starch grains in the medullary-rays of the wood of the Cartagena variety. (See Schneider, *Jour. of Pharmacology* (*N. Y. C. P.*), 1897, p. 1; and Collin, *J. P. C.,* xx, p. 293.) Hartwich (*Ap. Ztg.,* xxvi, p. 57), however, points out that the size of the starch grains is not sufficient to differentiate these varieties and states that there is a greater difference in the cells of the woody portion of the root.

"**Assay.**—Proceed by Type Process A, taking 10 Gm. of Ipecac, using 100 cc. of ether and decanting an aliquot portion of 50 cc., representing 5 Gm. of Ipecac. Use ether for the final extraction and determine the alkaloids volumetrically. Each cc. of tenth-normal acid corresponds to 0.024 Gm. of the ether-soluble alkaloids of Ipecac (Proximate Assays)." *U. S.*

" Shake 7 grammes of the Root, in No. 60 powder, frequently during 5 minutes with 70 millilitres of a mixture of 1 volume of *chloroform* and 3 volumes of *ether;* add 5 millilitres of *solution of ammonia* and shake frequently during one hour; then add 5 millilitres of *water* or sufficient to make the powder agglomerate on violently shaking. Separate 50 millilitres of the clear liquid, and shake first with 10 millilitres of *N/10 solution of hydrochloric acid,* and then with three successive portions, each of 3 millilitres, of *water.* Mix the several aqueous solutions, make alkaline with *solution of ammonia,* and shake out first with 10 millilitres and then with three successive portions, each of 5 millilitres, of a mixture of 6 volumes of *ether* and 1 volume of *chloroform.* Mix the several ethereal solutions, evaporate, dry the residue at 80° C. and weigh. It weighs not less than 0.100 gramme. Powdered Ipecacuanha Root, when used for official purposes other than the production of standardised preparations, must be adjusted, if necessary, by the addition of powdered Milk Sugar to contain in 100 grammes when tested by the foregoing process 2 grammes of the alkaloids of Ipecacuanha Root. *Limit of error* 0.1 gramme in excess or defect." *Br.*

According to the researches of A. R. L. Dohme (*A. J. P.,* 1895), the stems adhering to the ipecac roots contain from fifteen to twenty per cent. less of the alkaloids than do the roots themselves. Moreover, it appears to be established that the portions of the stem distinct from the root contain much less of the alkaloids than does the base of the stem, so that the Pharmacopœia very properly directs that not more than 7 cm. of the stems shall be allowed. The bark of ipecac root should make eighty per cent. of the whole. When the bark in either variety of ipecac is opaque, with a dull amylaceous aspect, the root is less active. As the woody part is nearly inert, and much more difficult of pulverization than the cortical it often happens that, when the root is powdered, the portion last remaining in the mortar possesses scarcely any emetic power, and care should be taken to provide against any defect from this cause. The German Pharmacopœia provides for the rejection of the last fourth of the powder.

Constituents.—The alkaloid emetine found in ipecac by Pelletier, in 1817, was shown by Paul and Cownley (*A. J. P.,* 1895, p. 256, and 1901, p. 87) to consist of three alkaloids, *emetine, cephaeline,* and *psychotrine.* J. U. Lloyd reports the presence of another alkaloid which he called *kryptonine* but subsequently changed to *emetoidine*. More recently, Hesse (*P. J.*, 1914, xciii, p. 425) reported two new bases, *ipecamine* and *hydroipecamine*. These are of minor importance only as shown by the researches of Pyman, quoted later. Willigk discovered *ipecacuanhic acid*, which was shown by Reich (*A. Pharm.* (2), cxiii, p. 208) to be a glucoside and to have the formula $C_{14}H_{18}O_7$. Finnemore and Braithwaite (*Trans. Br. Ph. Con.*, 1912, p. 496) confirmed the glucosidal nature of this body and suggested the name *ipecacuanhin*.

There has been considerable dispute as to the composition of the ipecac alkaloids, especially of emetine. The United States Pharmacopœia gives $C_{30}H_{44}O_4N_2$, which is the formula of Paul and Cownley. Kunz-Krause later suggested $C_{30}H_{44}O_5N_2$. Still later Hesse proposed the formula $C_{30}H_{42}O_4N_2$, but subsequently he accepted the Kunz-Krause formula. Carr and Pyman (*Proc. Chem. Soc.*, 1913, xxix, 226), however, believe that the proper formula for emetine is $C_{29}H_{40}O_4N_2$. Carr and Pyman give for the formula of cephaeline, $C_{28}H_{38}O_4N_2$. According to Carr and Pyman, psychotrine has the formula $C_{28}H_{36}O_4N_2$. In 1917 Pyman isolated *o-methylpsychotrine*, $C_{29}H_{38}O_4N_2$, from the non-phenolic group of ipecac alkaloids (the emetine group), and also *emetamine*, $C_{29}H_{36}O_4N_2$. This latter alkaloid differs from *emetine* in containing two unsaturated linkages.

There is evidently a close inter-relationship between the various ipecac alkaloids. Pyman (*Tr. Chem. Soc.*, 1917, cxi, 438) has shown that psychotrine can be converted either into o-methylpsychotrine or into cephaeline, which in turn, upon methylation, yields emetine. A stereo-isomeride of emetine called *isoemetine* has been produced by Pyman from *methylpsychotrine* by reduction.

Browne (*J. A. Ph. A.*, 1917, vi, 1043) has made some further investigation of Lloyd's *kryptonine* (emetoidine). It is a colloidal base of a red color and very bitter. It is an emetic by local action and when injected intravenously it lowers the blood pressure similarly to emetine. It is less toxic to paramecia and to rabbits, than emetine.

Huerre (*J. P. C.*, 1920, xxi, 425) believes that the tannin-like body *ipecacuanhic acid* also plays a rôle in ipecac therapy. This acid which exists in the root to the extent of 3 or 4 per cent. is of a glucosidal character. According to Paul and Cownley, the melting point of emetine is 60° C., of cephaeline 102° C., and of psychotrine 138° C. Psychotrine and its salts are rapidly decomposed on exposure to light, in this respect differing from emetine and cephaeline, neither of which are affected by light. It crystallizes from ether, in prisms of lemon-yellow color.

The medicinal virtues of ipecac reside chiefly, if not solely, in the alkaloids emetine and cephaeline. Different samples of ipecac root vary not only in the total percentage of alkaloidal contents, but also in the proportion of the alkaloids, and the question whether Rio and Cartagena ipecac ought to be considered as interchangeable remedies has become one of importance. Paul and Cownley (*A. J. P.*, 1901, lxxiii, 57), as the result of an exhaustive study, found that the two ipecacs do not differ materially in the total amount of alkaloid contained, but that whereas in the Brazilian root emetine is the dominant alkaloid, in the Colombian root cephaeline predominates, and that therefore the two roots cannot be considered as therapeutically identical. This work of Paul and Cownley has been confirmed by Carl Lowin (*A. I. P. T.*, 1902), so that it would appear to be settled that in general terms Rio ipecac contains 1.5 per cent. of emetine and 0.5 of cephaeline; Cartagena contains 0.9 of emetine and 1.2 of cephaeline. The practical accuracy of these researches, however, has been challenged by the large dealers in the products of ipecac. In 1903, as the result of twenty assays of different lots of each drug, Cæser and Loretz, of Halle, report the results given in the following table:

	Total Alkaloids.	Emetine.	Cephaeline.	Ash.
Rio (Matto Grosso Root)	2.73	1.98	0.50	3.34
Rio (Bahia Root)	2.19	1.36	0.63	3.21
Indian from Johore	2.45	1.46	0.62	2.93
Cartagena	2.75	1.47	1.39	6.02

Formerly Brazilian ipecac commanded in the American market a higher price than did the Cartagena variety. At times the Cartagena ipecac has been from ten to fifteen cents a pound higher than the Brazilian, indicating that in some way it especially recommends itself to the manufacturing pharmacists.

W. G. Whiffen patented in Germany in 1898 a process for making emetine, basing it on the separation of emetine hydrobromide from extract of ipecac; cephaeline hydrobromide crystallizes with great difficulty, while emetine hydrobromide is easily crystallized and separated. (*C. D.*, 1898, 694.)

According to the researches of Tokuye Kimura (*A. J. P.*, 1903, 1), ipecacuanhic acid occurs as a brown, hygroscopic, amorphous mass, freely soluble in warm water and alcohol but very slightly soluble in cold water or ether, insoluble in chloroform, having the formula $C_{17}H_{26}O_{10}$ or a multiple of the same. As a glucoside it is allied to the saponin acids but has no hemolytic action and does not form soapy solutions. Its most characteristic reaction is that its solution strikes with ferric chloride a green alizarin tint, which, by the addition of ammonia or saturated baryta water, changes to violet or blackish, with the final separation of a blackish-brown precipitate. On the addition to the discolored solution of diluted hydrochloric acid the green color returns. According to the experiments of Kimura, ipecacuanhic acid is readily absorbed but is possessed of feeble physiological activity and is not germicidal, so that the value of ipecac in dysentery can scarcely depend upon its presence.

The double salts of bismuth iodide and ipecac alkaloids which are sparingly soluble in acids but hydrolyzed by weak alkalies, and which therefore pass through the stomach with little or no dissociation have been recommended for the therapeutic applications of this drug. For methods of preparing this compound, see *Ph. Wb.*, 1919, lvi, 786 and *Proc. A. Ph. A.*, 1919, 521.

Uses.—Ipecac was employed as an emetic by the natives of Brazil when that country was first settled by the Portuguese, but, though described in the work of Piso, it was not known in Europe until 1672, and did not come into use until some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecac into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was drawn to it, and the fortunate physician received from Louis XIV a large sum of money and public honors on the condition that he should make it public.

Ipecac is in large doses emetic, in smaller doses, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to cause vomiting, it produces nausea, and frequently acts on the bowels. As an emetic it is mild, but tolerably certain, and free from corrosive or narcotic properties.

The researches of Waters and Koch (*J. P. Ex. T.*, 1917, x, 73) have shown that psychotrine is practically non-toxic and probably plays no part in the action of ipecac. Cephaeline and emetine are similar in their effects although differing in degree. Emetine is a more active amebicide but less irritant and emetic, and also less toxic, than cephaeline. Eggleston and Hatcher (*J. P. Ex. T.*, 1915, vii, 225, and 1923, xxi, p. 1) have found that both of these alkaloids have a direct stimulant action upon the vomiting center in the medulla. They believe, however, that the emetic effect is due not only to this action but in part to their local irritant effect upon the gastric mucosa. Because of the promptness with which the emesis occurs it is scarcely possible for enough of the active principles to be absorbed from the stomach to produce direct systemic effects. When injected subcutaneously or intravenously in large dose, however, the alkaloids act as depressants to the motor side of the spinal cord and probably also to the respiratory center. It would seem that they have some special predilection for the lungs for after toxic doses alternating areas of pallor and intense hyperemia have been found in the pulmonary tissue.

Originally introduced into Europe as a remedy for *dysentery,* ipecac for centuries was alternately lauded as a specific and condemned as useless in this disease. In 1911 Vedder (*Bull. Manila Med. Soc.*, March, 1911; also *J. A. M. A.*, 1914, lxii, p. 501) showed that an infusion of ipecac representing one part of the drug in ten thousand destroyed the viability of the *Entamebæ,* and that the alkaloid emetine in a one to one-hundred thousand solution had the same effect. He also showed that the drug was possessed of no bactericidal virtues. Since this research, reasons for the diversions of opinion as to the usefulness of ipecac are apparent. There are two types of dysentery, one due to a specific ameba and the other caused by a bacillus. In the latter form of the disease the drug is useless but is probably the most efficacious remedy we possess in the amebic type of dysentery. The great difficulty in its employment has always been to obviate the emetic effect which sometimes made it almost impossible to get enough of the drug into the intestinal tract to have an effect. In 1912 Rodgers (*B. M. J.*, 1912, i, p. 1424, and ii, p. 405) introduced the hypodermic administration of the alkaloid emetine which has since then become the standard treatment of *amebic dysentery.* (See *Emetinæ Hydrochloridum.*) Simon (*J. A. M. A.*, 1918, lxxi, 2042) maintains that the whole drug administered by mouth gives better results than the subcutaneous injection of the alkaloid, especially in the chronic cases where the ameba has become encysted. Ipecac is also of value in the various sequelæ of dysentery, such as *abscess of the liver,* although it does not always produce complete cure. Following the announcement of Smith and Barrett (*J. A. M. A.*, 1914, lxiii, 1746) that *pyorrhea alveolaris* was due to a specific ameba, emetine was employed to a considerable extent in tooth pastes and mouth washes in this condition. The present evidence, however, indicates that the ameba found in the mouth in this disease is not the causative agent, and there is no convincing evidence of the curative value of emetine.

As an emetic ipecac is rarely used merely for the purpose of evacuating the stomach, but when an action upon the portal circulation is desirable, as in the so-called *biliousness* or *acute alcoholism,* it is often of service. Many clinicians believe that it has a direct influence upon hepatic secretion, but it is more probable that its effects upon the liver are due simply to its emetic action. By virtue of their nauseating effect small doses of ipecac tend to increase various secretions of the body, thus it is widely used as a diaphoretic, especially in combination with opium (see *Pulvis Ipecacuanhæ et Opii*) in the early stages of *acute coryza* and other mild infections. In the same way it acts as an expectorant, and in the early stages of *acute bronchitis* it is one of the most valuable remedies we possess. Many years ago Trousseau affirmed that ipecac possessed valuable hemostatic powers, especially useful in *hemoptysis,* but this use of it failed to receive general recognition. The treatment has been revived by Flandin (*Press. Med.,* 1913) and other French clinicians.

As an emetic ipecac may be given in substance in the dose of twenty to thirty grains (1.3–2.0 Gm.), repeated in fifteen to twenty minutes if necessary. As an expectorant the syrup is generally preferred. If ipecac itself is used in dysentery it should be given in doses of five grains every hour combined with opium to prevent vomiting. To obviate the nauseating effect of emetine when given by the mouth, Bass and Johns have used a combination with Lloyd's reagent.

Under the name of *riopan,* a preparation asserted to contain 50 per cent. of combined cephaeline and emetine has been introduced. This is marketed in the form of tablets each containing one-thirtieth of a grain (0.002 Gm.), which is stated to be equivalent to about a grain and a half of ipecac (0.096 Gm.).

Dose, emetic, twenty to thirty grains (1.3–2.0 Gm.); nauseating, two grains (0.13 Gm.); diaphoretic, one grain (0.065 Gm.); stomachic, one-fourth to one-half grain (0.016–0.032 Gm.).

IPOMŒA. U. S. (Br.)

IPOMEA Ipom. [Orizaba Jalap Root, Mexican Scammony Root]

"Ipomea is the dried root of *Ipomœa orizabensis* Ledenois (Fam. *Convolvulaceæ*). Ipomea yields not less than 15 per cent. of the total resins of Ipomea, and not more than 3 per cent. of acid-insoluble ash." *U. S.*

"Orizaba Jalap Root is the dried root of Ipomœa orizabensis, *Ledanois.*" *Br.*

Ipomœæ Radix, *Br.;* Orizaba Root, Male Jalap, Light, Woody, or Fusiform Jalap; Jalap stalks; Purgo Macho (*Mexican*).

The genus *Ipomœa* (Fam. *Convolvulaceæ*) comprises about 300 species of herbs and shrubs, some being erect, others prostrate, but very many climbing. They are remarkable for their showy flowers, as in *I. purpurea,* the common morning glory of the garden. Many of the species produce large tuberous roots which contain a drastic purgative resin and several of them have been used in medicine. Because of the growing scarcity of scammony, the B. P. 1914 permitted the employment of the resin of Orizaba jalap root to be used in formulas calling for scammony resin, and the U. S. P. X omitted scammony altogether, substituting the Orizaba jalap.

Ipomœa orizabensis is a climbing vine indigenous to Mexico. It produces a large, fusiform, more or less branching root attaining a length of 5 dm., yellow on its outer surface, milky-white within. The stem is cylindrical, slightly villous and climbing. The leaves are large, petiolate, cordate, acuminate and villous on the veins. The corolla is campanulate and reddish-purple. The capsule is 2-locular and one-seeded. The roots are gathered around Orizaba in the Mexican Andes, cut into transverse disks and rapidly dried in the sun. It is exported from Mexico City to the United States.

Power and Rogerson (*A. J. P.,* 1908, p. 255) have shown that the root of the *I. purpurea* or common morning glory, contains a purgative resin. Shimoyama has found in the *I. triloba* (*Pharbitis triloba*) of Japan a similar resin and according to Hyrano the seeds of this plant have long been used in Japan under the name of "kengashi." *Turpeth,* the root of the East Indian *I. Turpethum,* was at one time recognized by the French Codex under the name of *Turbith Végétal.*

Ipomea root becomes official in the U. S. P. X not because of any therapeutic superiority to Levant scammony root, but as the nearest available substitute for a valuable drug which has not been commercially obtainable for a number of years. Besides being yielded by a species of a different genus, it shows marked structural differences. Whereas Levant scammony root occurred in cylindrical, grayish- to reddish-brown, usually twisted segments, from 10 to 25 cm. in length, ipomea occurs in nearly flat, light- or dark-brown, transverse slices or in pieces of irregular shape, made by vertical or oblique sectioning of these slices, and whereas scammony was mottled internally by the apparently scattered appearance of its bundles in the parenchyma, that of ipomea is not mottled and shows a regular concentric arrangement of its bundles. Moreover, Levant scammony root contained calcium oxalate crystals only in monoclinic prisms and possessed a variety of stone cells, while Ipomœa contains calcium oxalate crystals chiefly of the rosette aggregate type, only an occasional rhombohedral crystal being found, and stone cells are absent.

Description and Physical Properties.—"*Unground Ipomea.*—Nearly flat transverse slices, from 2 to 12 cm. in diameter, and from 1 to 5.5 cm. in thickness; externally light to dark brown, very deeply wrinkled; fracture tough, fibrous, cut surface light brown, showing concentric rings from which coarse fibers protrude; odor distinct, somewhat aromatic; taste slightly sweet, becoming somewhat acrid.

"*Structure.*—A corky layer consisting of several rows of brownish, thin-walled, narrow tabular cells; outer cortex of several layers of colorless, thin-walled cells; a broad cortical layer made up of thick-walled, tangentially elongated cells, containing either starch grains or crystals of calcium oxalate and numerous large cells containing brown resinous latex; alternate rings or zones of collateral fibrovascular bundles separated by broad medullary rays; sieve in semicylindrical strands outside of the wood wedges; resin cells numerous and distributed throughout the parenchyma and medullary rays; the parenchyma cells both in and surrounding the bundles more or less collapsed and containing either starch or calcium oxalate crystals.

"*Powdered Ipomea.*—Light grayish-brown; starch grains from 0.003 to 0.035 mm. in diameter, mostly single, also 2- to 4-compound and usually with a central cleft; calcium oxalate crystals numerous, mostly in rosette aggregates, occasionally in the form of rhombohedra, from 0.010 to 0.045 mm. in length; fragments of yellowish-brown resin cells; tracheæ mostly with bordered pores and associated with numerous thick walled wood fibers with simple pores.

"**Assay.**—Proceed as directed under *Jalapa.*" *U. S.*

It is described in the Br. as follows: "In irregular, tough, or fibrous pieces of varying size and shape, but often in portions, three to five centimetres wide and two to four centimetres thick, of transverse slices of large roots. Externally greyish-black and wrinkled, internally greyish or brownish. From the transverse surface coarse fibres protrude in irregular concentric circles. Slight odor; taste faintly acrid. Yields to *alcohol* (90 per cent.) a resin which has the properties enumerated under 'Scammoniæ Resina.'" *Br.*

Constituents.—The purgative power of ipomea undoubtedly resides in its resin. Dean determined the amount of resin in a specimen and, in a separate paper, gives the method employed and the results, as follows: The drug was powdered, exhausted by percolation with alcohol (90 per cent.), the greater part of the alcohol distilled off, and the resulting strong tincture poured into three times its volume of water. The resin separated as a mass of honey-like consistence. It was well washed with boiling water until the washings were free from sugar and from color, and then dried on a water bath until the weight was constant. The yield of resin amounted to 18.5 Gm. from 100 Gm. of the powdered drug; this is the highest percentage yet recorded from this source. The dried resin was pale brown, and almost entirely soluble in ether, the insoluble portion from 18.5 Gm. weighing less than 0.25 Gm. It has the general characteristics of scammony resin. The powdered drug, dried at 100° C., yielded 9.89 per cent. of ash. (*P. J.*, March 5, 1904.) Power and Rogerson (*Tr. Chem. Soc.*, 1912, ci, 398) obtained approximately 15 per cent. of resin of which from 70 to 75 per cent. was soluble in ether. Taylor (*A. J. P.*, 1909, lxxxi, 105), however reported that from 96 to 99 per cent. of the resin of Mexican scammony was ether-soluble.

Speaking in a general manner ipomea resin has a higher specific rotatory power than the scammony resin and a lower ester and saponification value. These differences, however, are not great enough to make a trustworthy distinction (see *Resina Ipomœæ*).

Uses.—Although ipomea has been admitted as a substitute for scammony, the therapeutic identity of the resins from the two is open to serious question. According to Bourdier (*J. P. C.*, 1912, 252), the ipomea resin is more irritant and likely to provoke nausea than true scammony. It is stated (*J. P. C.*, xxiv, 166) that thirty to sixty grains (2–3.9 Gm.) of ipomea root is actively purgative. It is, however, rarely employed and is official only as a source of scammony resin.

Off. Prep.—Resina Ipomea, *U. S.*

ISPAGHULA. Br.

ISPAGHULA

"Ispaghula consists of the dried seeds of Plantago ovata, *Forsk.*" *Br.*

Ispaghue, Spogel Seeds.

Plantago ovata Forskal (*P. Ispaghula* Roxb.) is a herbaceous plant (Fam. *Plantaginaceæ*) growing in India and Persia and extending westward to Spain and the Canary Islands. It is either erect or decumbent and varies in height from 2.5 cm. to 1 dm. The leaves are ovate and either glabrous or shaggy hairy. The flower spikes are either cylindrical or reduced to a globular head. The seeds closely resemble those of other species of *Plantago.*

They are described as follows: "Seeds boat-shaped, somewhat acute at one end, from two to three millimetres long and from one to one and a half millimetres wide; pale greyish-brown, with a darker elongated spot on the convex side; on the concave side the hilum covered with the remains of a thin white membrane. In *water* the testa swells, producing a viscous mucilage. No odor or taste." *Br.*

The seeds of the *Plantago amplexicaulis* Cav. are also sold in the Indian bazaars as Ispaghula. They resemble the official seeds, but are of a darker color.

The seeds of *Plantago Psyllium* L., commonly known as flea seeds, are smaller than the official seeds; they are described in Part II.

Ispaghula seeds yield to water a viscid mucilage. They are used in India as a demulcent in *dysentery* and various intestinal irritations, and are also slightly laxative. On roasting they are said to become astringent, and as such are used for *diarrheas,* especially of children. By European practitioners they have been chiefly employed in *chronic diarrhea.* In India they are also used for their demulcent effect in catarrhal conditions, especially of the genito-urinary tract.

Dose, from one to two and a half drachms 3.9–9.8 Gm.).

Off. Prep.—Decoctum Ispaghulæ, *Br.*

IRIS. N. F.

ORRIS [Orris Root]

"Orris is the rhizome of *Iris florentina* Linné, *Iris germanica* Linné, or *Iris pallida* Lamarck (Fam. *Iridaceæ*), freed from the roots, peeled and dried. Orris contains not more than 1 per cent. of foreign organic matter." *N. F.*

Iridis Rhizoma; Rhizoma Iridis, *P. G.;* Radix Iridis Florentinæ, Radix Ireos, Iris de Florence, *Fr.;* Florentinische Violenwurzel, Veilchenwurzel, *G.;* Ireos, *It.;* Lirio de Florencia (Rizoma de), *Sp.*

In all the species belonging to this genus, so far examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, *Iris fœtidissima* L., *I. pseudacorus* L., and *I. tuberosa* L. have at various times been admitted into use, in addition to those here described.

The three species recognized, under the title "Iris," by the N. F. are valued rather for their pleasant odor than for their cathartic properties. The *Iris versicolor* is described in the succeeding article.

Iris Germanica, commonly known as *Fleur-de-Lys,* is a perennial herb with dark blue or purplish flowers, native to central and southern Europe, but extensively cultivated as an ornamental plant in the United States and has become sparingly naturalized in Virginia. It is cultivated on a commercial scale in Italy, especially in the neighborhood of Verona, and also in Morocco. *I. pallida,* Lam. which is a native of the eastern Mediterranean countries, has pale bluish flowers. The rhizomes of these two species constitute what is known as *Verona Orris.* The *Florentine orris* is from the *I. Florentina* L. It has large white flowers and is of about the same distribution as the *I. pallida.* Its rhizome is generally the most fragrant although it is less widely cultivated than the other two species.

The rhizomes of these three species resemble one another so closely that it is often impossible to distinguish between them. They are gathered usually in the late summer from plants two or three years old and dried in the sun. The fresh rhizomes are without odor and have an acrid taste, but during the process of drying they lose much of their acridity and develop the characteristic fragrance. The Florentine variety is usually lighter in color and more pronounced in odor than the Veronese and also more carefully peeled. The commercial supplies of orris root come to the U. S. A. from Leghorn, Italy, and to a lesser extent from Mogador, Morocco.

Description and Physical Properties.—"*Unground Orris.*—In pieces of various forms and sizes, usually jointed and branched, from 5 to 10 cm. long and from 1.5 to 3 cm. wide, rounded or flattened, with knotty enlargements; under surface with numerous root scars, the upper with leaf scars; externally yellowish white; internally light yellow; fracture hard, rough and at times mealy, showing a narrow cortex, a distinct endodermis and a large stele with numerous vascular bundles, especially near the endodermis. Odor fragrant, resembling that of violet flowers; taste slightly aromatic, bitterish, somewhat irritating.

"*Structure.*—Cortex composed mostly of starch-bearing parenchyma, the cells with thickened, porous walls and intercellular spaces within which occur large prisms of calcium oxalate which are also found in certain parenchyma cells with suberized walls; a distinct endodermis of collenchyma-like cells containing starch; a large central cylinder composed of starch-containing parenchyma with concentric vascular bundles irregularly placed throughout, the latter being most numerous near the endodermis.

"*Powdered Orris.*—Light yellow. Parenchyma cells of the cortex and central cylinder filled with characteristic starch grains, the latter oval, rounded at one end and flattened at the other, some curved or with irregular protuberances, mostly single, from 0.020 to 0.050 mm. in length and with an X-shaped cleft in the large rounded end of the grain, two of the fissures extending in the form of a horseshoe toward the small end of the grain; elements of vascular bundles, with tracheæ showing spiral, annular, scalariform or reticulate markings, the tracheæ from 0.010 to 0.025 mm. in width; calcium oxalate in prisms up to 0.500 mm. in length and 0.030 mm. in width." *N. F.*

Orris root contains much starch, a bitter and acrid fixed oil or soft resin and a crystallizable volatile oil. According to Landerer (*A. Pharm.,* lxv, p. 302), the acrid principle is volatile and separates in the form of a steareopten from water distilled from the root. By distillation with steam the root yields about 0.1 or 0.2 per cent. of a semi-solid aromatic substance known as *oil of orris* or powder of orris. Flückiger (*A. J. P.,* 1876, 411; 1885, p. 133) has shown that this consists chiefly of myristic acid containing a small amount of the true odorous principle. The myristic acid, however, seems not to pre-exist in the orris root, but is probably liberated from a fat by the influence of the steam. The fragrance of the root has been shown by Tiemann to be due to *irone* ($C_{13}H_{20}O$) which is a methyl ketone isomeric with ionone. In attempting its synthesis, Tiemann prepared an isomeric compound *pseudoionone* which however did not possess a pleasant odor but could be changed into *ionone* which has the violet-like odor. This complex ketone is now manufactured synthetically for use in perfumery. Ionone, of commerce, is a mixture of *alpha* and *beta* isomers which have been successfully separated. *Alpha ionone* has a sweet penetrating odor resembling orris while *beta ionone* is said to more closely resemble the violet odor.

Uses.—In large doses, orris root is cathartic and emetic and was formerly employed as a medicine. At present it is valued chiefly for its agreeable odor. It is occasionally chewed to conceal an offensive breath and enters into the composition of tooth powders.

Off. Prep.—Species Pectorales, *N. F.*

IRIS VERSICOLOR. N. F.

BLUE FLAG [Iris Vers.]

"Blue Flag is the dried rhizome of *Iris versicolor* Linné, or of *Iris caroliniana* Watson (Fam. *Iridaceæ*). Blue Flag contains not more than 5 per cent. of its roots and leaf bases or other foreign organic matter." *N. F.*

Blue Flag, Larger Blue Flag; Amerikanische Schwertel, *G.;* Iris Varié, *Fr.*

Iris versicolor L., or blue flag, is found in all parts of the United States, flourishing in low wet places in meadows.

The somewhat leafy stem is taller than the equitant basal leaves and often branched; the flowers are a violet blue variegated with green, yellow or white and purple-veined. They afford a blue infusion which has been used as a test for acids and alkalies. The fresh rhizome is almost odorless and has a nauseous, acrid taste; the acrimony and apparently also the medicinal activity is impaired by age. According to Andrews, however, if cut, when fresh, into slices, dried at the temperature of about 37.8° C., then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time. Commercial supplies of this drug have been recently obtained from Florida, Missouri, New Jersey, New York, Michigan and North Carolina.

Description and Physical Properties.—"*Unground Blue Flag.*—Rhizome frequently branched, up to 20 cm. in length and 3 cm. in thickness at the nodes, usually cut into longitudinal pieces; outer surface grayish brown to purplish brown, somewhat annulate, the upper surface with markings of leaf bases, the lower with numerous root scars and root remnants; fracture short, the broken surface yellowish white, pink or pale to dark purplish brown and exhibiting a central stele with whitish fibrovascular bundles distributed throughout, a distinct endodermis, and cortex. Odor slight, not distinctive; taste acrid, nauseous.

"*Structure.*—A more or less exfoliating epidermal layer of cells with brownish walls; a hypodermis of about two rows of cells with uniformly thickened, strongly lignified walls, some of which contain a reddish-brown amorphous substance; a narrow cortex of characteristic structure with ovoid or spheroidal parenchyma cells with large intercellular spaces, some of the parenchyma containing starch, others a reddish-brown amorphous substance; an endodermis of a single layer of cells with walls lignified and thickened on the inner and radial surfaces; a central cylinder made up of numerous nearly spherical parenchyma, between which are intercellular spaces not as large as those in the cortex; concentric vascular bundles occasional in the cortex, more numerous in the parenchyma of the central cylinder.

"*Powdered Blue Flag.*—Reddish-brown; numerous resin cells filled with a reddish-brown amorphous substance; starch grains few, or in some specimens abundant, simple or 2- to 4-compound, the simple grains being spherical or elliptical, up to 0.022 mm. in diameter; calcium oxalate in prisms up to 0.350 mm. in length; tracheæ with spiral or reticulate markings or bordered pores; fibers few, lignified and with oblique pores." *N. F.*

The active principle of blue flag is unknown. The name *iridin* is applied to the oleoresin obtained by precipitating the tincture of the root with water. *Irisin* is a somewhat similar preparation in which the oleoresin is stiffened by the addition of the powdered root. For chemical examination of the resin see Power and Salway (*A. J. P.*, 1911, lxxxiii, p. 14).

Uses.—Blue flag root is a cathartic and emetic said to have been used by the Indians of the Southern United States. By some it is supposed to have a special effect upon the liver and is used as a cathartic in *biliousness.* The eclectic physicians attribute to it also alterative powers and employ it in various *skin diseases, chronic rheumatism* and similar complaints.

Dose, ten to thirty grains (0.6–2 Gm.).

Off. Prep.—Fluidextractum Iridis Versicoloris, *N. F.;* Elixir Corydalis Compositum, *N. F.;* Fluidextractum Stillingiæ Compositum, *N. F.;* Syrupus Stillingiæ Compositus, *N. F.*

JALAPA. U. S., Br.

JALAP Jalap.

"Jalap is the dried tuberous root of *Exogonium Jalapa* (Nuttall et Coxe) Baillon (Fam. *Convolvulaceæ*). Jalap yields not less than 7 per cent. of the total resins of Jalap." *U. S.* "Jalap consists of the dried tubercules of Ipomœa Purga, *Hayne.*" *Br.*

Radix Jalapæ, Jalapæ Radicis Tubera; Jalap Tubéreux, *Fr. Cod.;* Tuber Jalapæ, *P. G.;* Jalape, Jalapenknollen, Jalapenwurzel, *G.;* Gialappa, Sciarappa, *It.;* Jalapa (Raiz de), *Sp.*

The botanical origin of jalap has long been a subject of much controversy among botanists. Linnæus, at first, is said to have placed the plant in the genus *Mirabilis.* In 1827, J. R. Coxe of Philadelphia grew jalap plants from tuberous roots he received from Mexico. These plants were studied by Nuttall who, in 1830, published a description of the species, naming it *Ipomœa Jalapa,* Nutt. and Coxe. During the same year

Scheide and Wenderoth published separate descriptions of the plant, the former naming it *Convolvulus jalapa* Scheide and the latter *Convolvulus Purga* Wenderorth. But Scheide and Wenderoth, apparently working with dried material, overlooked the true character of the stigma of the jalap flower which is simple and capitate, a character which distinguishes *Ipomœa* from *Convolvulus,* the latter genus having two linear or ovate stigmas. In 1833, Hayne published a monograph on the species, reinstated it in the genus *Ipomœa* and named it *Ipomœa Purga* (Wenderoth) Hayne (*Arzneigew.,* 1833), a name which has persisted in the British Pharmacopœia. Choisy, in 1833, divided the Ipomœas and placed those bracteate forms having exserted stamens and salverform corolla in his genus *Exogonium.* This group is recognized as a genus by Peter and Hallier but merely as a section of Ipomœa by Griesebach and Meissner. In 1840, Bentham described the species (*Pl. Hartw.,* 1840) first placing it in the genus *Exogonium* and naming it *Exogonium Purga* (Wenderoth) Bentham, a name which was later adopted by Engler in his *Syllabus der Pflanzenfamilien* and by the U. S. IX. In 1884, Baillon, recognizing the priority of the specific name *Jalapa* which had been established by Nuttall and Scheide, again revised the nomenclature and assigned to it the name of *Exogonium Jalapa* (Wenderoth) Baillon (*Bot. Med.,* 1884, xi, 1263). This name has been adopted in the U. S. X.

The root of *Exogonium Jalapa* (*Ipomœa Purga* Hayne) is a roundish, somewhat pear-shaped tuber, externally blackish, internally white, with long fibers proceeding from its lower part, as well as from the upper root-stalks. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighboring objects, about which it twines. The leaves are petiolate, heart-shaped, entire, smooth, pointed, deeply sinuated at the base and prominently veined on their under surface. The lower leaves are nearly hastate or with diverging angular points. The flowers, which are large and of a lilac-purple color, stand upon peduncles about as long as the petioles. Each peduncle supports two or, more rarely, three flowers. The calyx is without bracts, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate.

The jalap plant is a native of Mexico, where it is dug during the whole year, and usually dried over the hearths of the Indian huts. Because of this method of drying over fires, the drug usually possesses a smoky odor and taste. It derives its name from the city of Jalapa, in the state of Vera Cruz, in the neighborhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from Vera Cruz and Mexico City in bags containing usually between 100 and 200 pounds. It has also been cultivated in India, Jamaica, South America and Ceylon. For an account of the cultivation of jalap in Madras, see *Am. Drug.,* 1896, 127.

Description and Physical Properties.—"*Unground Jalap.*—Fusiform, irregularly ovoid or pyriform, the larger roots often incised or cut into pieces; from 4 to 15 cm. in length and from 1 to 10 cm. in diameter; externally dark brown, longitudinally wrinkled or furrowed and with numerous lenticels; hard, compact, not fibrous, internally light grayish-brown to dark brown, with a distinct brown cambium line; odor slight but distinctive and smoky; taste somewhat sweet and acrid.

"*Structure.*—Cork of several or many rows of small, thin-walled brownish cells; cortex narrow; fibro-vascular bundles small, numerous, arranged in several concentric zones, bicollateral, each bundle with several tracheæ, several small groups of sieve tissue and inconspicuous cambium except in the outermost zone where the cambium is conspicuous, with 6 to 10 rows of cells and forming a complete circle; parenchyma abundant, starch-bearing, with numerous large secretory cells scattered through it.

"*Powdered Jalap.*—Light brown; starch grains numerous, single or 2- to 3-compound, more or less swollen, ellipsoidal or ovoid with concentric or excentric lamellæ and radiating clefts, from 0.003 to 0.035 mm. in diameter; calcium oxalate in rosette aggregates from 0.010 to 0.035 mm. in diameter; tracheæ short, wide, with simple or bordered pores; secretory cells with yellowish brown, resinous contents." *U. S.*

Jalap is apt to be attacked by insect larvæ, which are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm-eaten drug is more powerfully purgative than that which is sound. Hence, worm-eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty by means of the microscope.

According to Herlant, even in powder it is easy to detect the presence of the root of *Mirabilis Jalapa,* which is sometimes used as an adulterant to jalap, by the presence of raphides of calcium oxalate.

Since about 1915 the root of *Piptostegia Pisonis* Mart. (Fam. *Convolvulaceæ*), commonly known as *Piptostegia Root* or *Brazilian Jalap,* has appeared in the American and European markets. It occurs in transverse, oval or circular sections up to .8 cm. in thickness. Its cut surface is pale yellowish-brown and shows many resin dots and several concentric rings. For structural details of this substitute see Farwell (*J. A. Ph. A.,* 1918, p. 854).

Jalap is usually kept by pharmacists in the state of powder, which is of a yellowish-gray color, and when inhaled irritates the nostrils and

UNIVERSITY OF ILLINOIS LIBRARY CHEMISTRY

throat, and provokes sneezing and coughing. Jalap yields its active properties partly to water, and completely to diluted alcohol.

"**Assay.**—Place 10 Gm. of Jalap in fine powder in a dry flask, add 50 cc. of alcohol and stopper the flask with a perforated cork holding a reflux condenser. (An open glass tube of not less than 0.6 M. in length will suffice.) Place the flask on a water bath, and digest for three hours with occasional shaking. Then transfer to a small percolator, allow to drain, and percolate with alcohol until the percolate measures 100 cc. Allow to cool to room temperature, and add alcohol to make exactly 100 cc. Mix well. Transfer 20 cc. of this tincture accurately measured, representing 2 Gm. of Jalap, to a separator, and add 10 cc. of chloroform and 20 cc. of a saturated solution of potassium citrate (20 Gm. of potassium citrate dissolved in 12 cc. of distilled water). Shake well during two minutes, then set aside for not less than ten hours or overnight. Draw off and discard the lower aqueous liquid, and filter the alcohol-chloroform solution through a small filter, wetted with alcohol-chloroform, into a tared flask or beaker. Rinse the separator with a mixture of 10 cc. of alcohol and 5 cc. of chloroform, and pass the rinsing through the filter. Mix the chloroformic liquids, evaporate on a water bath, dry at 100° C., and weigh." *U. S.*

Constituents.—The purgative powers of jalap undoubtedly reside in its resin. G. A. Kayser separated jalap resin into two parts, the first hard and insoluble in ether, the other soft and soluble in that menstruum. The ether insoluble portion he called *rhodeoretin* and showed it to be identical with the substance previously described by Buchner and Herberger under the name of *jalapin.* Mayer confirmed these observations. He gave the name of *convolvulin* to Kayser's rhodeoretin and by treating with alkalies obtained what he believed to be two glucosidal substances which he named *purgic* and *convolvulic acids.* Power and Rogerson (*J. Am. C. S.*, 1910, xxxii, p. 80) have found, however, that these substances are not chemical individuals. By successive extraction with various solvents they showed that the jalap resin was an extremely complex mixture. Approximately 10 per cent. of the total resin is soluble in ether. They found that the various fractions separated by successive treatment with ether chloroform and ethyl acetate were all about equally active as purgatives.

The terms *jalapin* and *scammonin* (or *convolvulin*) can no longer be regarded as names of definite substances. They are, however, often used to indicate different fractions of the Convolvulus resins, the term jalapin being applied to the ether soluble portion and convolvulin to the insoluble fraction.

The average percentage of resin in jalap has of late years distinctly lessened; indeed this fact has received official recognition. The U. S. P., 1890, required 12 per cent., and the French Codex, 1884, 16 to 18 per cent. The poor quality of commercial jalap appears to be due, not, as believed by Flückiger, to the extraction of the resin from the roots in Mexico, but to the fact that the wild tubers are collected indiscriminately from November to March; the cultivators of India are also very careless in their methods. The lowness of the U. S. P. standard (7 per cent.) is to be regretted, especially as the Br. Ph. requires 11 per cent., but it is probably necessary, practically, to meet the commercial conditions. From a compilation by M. I. Wilbert (*J. A. Ph. A.*, 1914, 1286) the range of 173 reported analyses of jalap was from 3.67 per cent. to 21.76 per cent. (For various analyses of commercial jalap, see *U. S. D.*, 18th ed., also *J. P.*, lxxii, p. 152.)

A comparison of various methods of assay was made by Dr. P. Seidler (*Ph. Ztg.*, 1912, No. 2, 15), who recommends the process of the P. G. V., which he says can be still further improved.

Tampico Jalap (*Purga de Sierra Gorda,* Mexican).—This drug closely resembles in appearance, odor, and taste the true jalap, but the tubers are somewhat smaller, more elongated and shrivelled. According to Ambrose Andouard, it is the *jalap digité majeur* of Guibourt. It grows along the Sierra Gorda, near San Luis de la Paz. In this place it is purchased from the Indians, and conveyed by mules to Tampico, where it enters into commerce. The plant differs from *Exogonium Jalapa* by its bell-shaped corolla and pendulous flower-buds. To it Hanbury gave the name *I. simulans.* (*A. J. P.*, July, 1870.) H. Spirgatis, of Königsberg, obtained a resin to which he gave the name of *tampicin.* Its physical properties are similar to those of the jalap resin. It is brittle, tasteless, inodorous, insoluble in water, soluble in ether and alcohol, and in solution has a feeble acid reaction. (See *N. R.*, 1871, p. 50.) The melting point of tampicin is 130° C.; its formula is $C_{34}H_{54}O_{14}$. The percentage of it yielded by the drug varies from a minimum of 10 per cent. (Hanbury) to a maximum of 15 per cent. (Umney). Andouard states that it is purgative.

Jalap should be rejected when it is light, of a whitish color internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said, when brought back, to have become consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Schacht and Wackenroder to a fungous growth. (*A. Pharm.*, xxxix, 239.)

Uses.—Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The aqueous extract obtained from jalap, previously exhausted by rectified spirit, is said to have no cathartic effect. Jalap was introduced into Europe in the latter part of the sixteenth or the beginning of the seventeenth century, and at one time ranked among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of *dropsy.* It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with potassium bitartrate.

The combination of jalap with calomel has long been popular, in the United States, in *bilious fever* and other complaints attended with *congestion of the liver* or portal circle.

In overdoses jalap may produce dangerous hypercatharsis. It is said to purge when applied to a wound. Jalapin when taken internally is probably absorbed, but as yet its presence has never been detected in the urine, and it remains uncertain whether it is eliminated or destroyed. Müller (*In. Dis.,* Dorpat, 1885) found traces of it in the blood, and even in the heart, lungs, and spleen of cats poisoned with it.

The *dose* of jalap, in powder, is from ten to thirty grains (0.65–2.0 Gm.).

"Juglans is the dried inner bark of the root of *Jugulans cinerea* Linné (Fam. *Juglandaceæ*) Juglans contains not more than 2 per cent. of adhering wood or other foreign organic matter." *N. F.*

Oil Nut; White Walnut; Ecorce de Noyer gris, *Fr.;* Graue Wallnussrinde, *G.*

J. cinerea is a tree extending in rich woods from New Brunswick to the mountains of Georgia and west to the Dakotas, East Kansas and Arkansas. It possesses rough gray bark and alternate imparipinnate leaves with 7 to 17 ovate-lanceolate leaflets having serrate margins and pubescent beneath. The fruit is an elongated ovate drupe containing a sweet edible oily kernel. The immature fruit is sometimes pickled for food purposes, and, when ripe, affords in its kernel a grateful article of food. The bark is used for dyeing wool a dark-brown color, though inferior for this purpose to that of the black walnut. It is said to be rubefacient when applied to the skin. The inner bark is the medicinal portion, that of the root being considered most efficient. It should be collected in autumn. The crude drug comes chiefly from North Carolina, Virginia and Michigan.

On the living tree, the inner bark, when first uncovered, is of a pure white, which immediately on exposure becomes a fine lemon color, and ultimately changes to deep brown. It has a fibrous texture.

Description and Physical Properties.—"*Unground Juglans.*—In quills, curved strips, or in chips, from 3 to 10 mm. in thickness; of a deep brown color on both surfaces and throughout, except for the faint, intersecting, whitish, radial, and tangential lines shown in the transverse section; outer surface smooth, somewhat warty; inner surface smooth and striate, bearing fragments of thin stringy fibers; fracture short, rather weak, somewhat fibrous. Odor faintly aromatic; taste bitter, astringent, somewhat acrid.

"*Structure.*—Outer bark, if present, exhibiting several layers of well developed cork cells containing starch or tannin or rosette crystals of calcium oxalate, and groups of stone cells; inner bark with numerous interrupted zones of bast fibers, a few crystal fibers and sieve tissue, alternating with layers of parenchyma cells containing starch or calcium oxalate or tannin, and traversed by somewhat wavy medullary rays, the latter mostly 1–4 cells wide.

"*Powdered Juglans.*—Dark brown; numerous rosette crystals of calcium oxalate, up to 0.055 mm. in diameter; simple rounded or occasionally 2- to 4-compound starch grains, the individual grains up to 0.015 mm. in diameter, sometimes with a cleft through the center; stone cells, some with thick walls, with simple or branching pores, up to 0.125 mm. long and 0.070 mm. wide, sometimes with reddish contents; long thick-walled fibers up to 0.032 mm. in width, occasionally associated with crystal fibers, the latter containing prisms of calcium oxalate from 0.010 to 0.050 mm. in length; parenchyma cells containing starch, calcium oxalate, tannin or oily drops; fragments of tissue composed of polygonal cells having yellowish brown walls, some with reddish-brown contents." *N. F.*

E. D. Truman (*A. J. P.,* 1893, 426) made proximate analyses of the root bark and the trunk bark for comparison. In the trunk bark, instead of the crystallizable juglandic acid, he found an uncrystallizable acid and a crystalline resin. Tanret and Villers isolated from the leaves a carbohydrate, *nucite,* which has since been shown to be identical with *inosite.* Tanret (*Jahresb. f. Pharm.,* 1876, 198) believed he had obtained an alkaloid from walnut leaves, which he proposed to call *juglandine.*

Extractum Juglandis. U. S. 1890. *Extract of Juglans.* "Juglans, in No. 30 powder, *one thousand grammes;* Diluted Alcohol, *a sufficient quantity.* Moisten the powder with *four hundred cc.* of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until *three thousand cc.* of tincture are obtained, or the Juglans is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*, 1890.

Several products of *Juglans regia* L., or common European *walnut,* are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in *syphilis* and for old *ulcers.* The expressed oil of the fruit has been deemed efficacious against the *tapeworm,* and is also used as a laxative injection. The leaves, long occasionally employed for various purposes in both regular and domestic practice, are astringent and bitter. For an exhaustive chemical examination of black walnut leaves by Miss L. J. Martin, see *A. J. P.,* 1886, p. 468. The leaves of *J. nigra* L. (*black walnut*), and those of *J. cinerea,* probably possess the same properties.

In 1872 Thiebaud found in the bark of the walnut tree a volatilizable acid—which he called *juglandic acid*—forming bright orange yellow crystals and apparently related to chrysophanic acid. According to Maisch this is identical with *nucin* (or *juglon*) which is found in pericarp of the European walnut (*A. J. P.,* 1874, p. 167).

It is generally believed that nucin of Vogel and *regianin* of Phipson are identical with juglon. *Juglon,* $C_{10}H_6O_3$, the characteristic constituent of the bark of *Juglans regia,* has been prepared synthetically by Bernthsen and Semper, and is now recognized as *a-oxynaphthoquinone,* $C_{10}H_5(OH)O_2$, as it can be made from dioxynaphthalene by the action of chromic acid mixture. It is in brownish-red, crystalline needles having a faint odor of walnut hulls, and is sternutatory. (*B. Chem. G.,* 1887, 934.)

Uses.—Juglans is a mild cathartic resembling rhubarb in its action, but less certain. It was much used during our Revolutionary war as an habitual laxative, and was especially esteemed by Rush in the treatment of *dysentery* and *hepatic congestions.*

Dose, from thirty to sixty grains (2–4 Gm.).

Off. Prep.—Fluidextractum Juglandis, *N. F.;* Elixir Cascaræ Sagradæ Compositum, *N. F.*

JUNIPERUS. N. F.

JUNIPER BERRY Junip.

"Juniper Berry is the carefully dried ripe fruit of *Juniperus communis* Linné (Fam. *Pinaceæ*). Juniper Berry contains not more than 10 per cent. of immature or discolored berries and not more than 3 per cent. of foreign organic matter." *N. F.*

Juniperi Fructus, *P. G.;* Baccæ Juniperi; Genevrier, *Fr. Cod.;* Genièvre, Baies de Genièvre, *Fr.;* Gemeiner Wachholder, Wachholderbeeren, *G.;* Ginepro, *It.;* Enebro, Bayas de Enebro, *Sp.*

Juniperus communis L. is an evergreen shrub, usually small, but sometimes twelve to fifteen feet high, with numerous very close branches, and thin, acerose leaves—occurring in 3's—from 12 to 21 mm. long and grayish on lower surface. The fruit is a subglobular galbulus containing three bony seeds.

The common juniper is a native of Europe and the northern regions of Asia and North America. *J. communis* var. *depressa* Pursh, the variety which thrives northward, is a trailing shrub, seldom more than 2 to 4 dm. high, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. Its leaves are up to 13 mm. long, green above, sharp-pointed, with a white stripe on their under surface. The common juniper flowers in May, but does not ripen its fruit until late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavor. The wood has a slight aromatic odor, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with the gum known commercially as *sandarach.*

The berries, as the fruit is commonly called, were formerly occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the south of Europe, particularly from Leghorn, Italy.

Description and Physical Properties.—"*Unground Juniper Berry.*—Nearly globular, about 8 mm. in diameter; externally smooth, shining black-brown to purplish black with a blue-gray bloom, at the apex a three-rayed furrow marks the cohesion of the three fleshy bracts forming the outer tissue; internally loosely fleshy, greenish brown, containing numerous large schizogenous cavities; seeds usually three, triangular ovate, hard, brown, with large uneven oil glands on the surface. Odor aromatic; taste sweet, pleasant, terebinthinate, slightly bitter.

"*Structure.*—Pericarp consisting of an epidermis of a row of rounded polygonal cells which contain a brownish granular substance and which become at the sutures of the bracts, blunt papillæ; a hypodermis of two or three rows of brownish red, collenchymatous cells; a fleshy portion composed of irregular loose parenchyma with large oval canals and traversed by fibro-vascular bundles with areolated fibers; inner layer of the pericarp of small thick walled cells many containing crystals of calcium oxalate; seed coat with a ring of stone cells of 2 to 10 rows, with very thick pitted walls, many enclosing prismatic crystals of calcium oxalate;

endosperm and embryo of the seed rich in fixed oil and aleurone grains.

"*Powdered Juniper Berry.*—Dark brown; fragments composed of stone cells, the latter up to 0.145 mm. in length; monoclinic prisms of calcium oxalate occurring either singly or within parenchyma or stone cells, from 0.005 to 0.030 mm. in length occasionally larger; numerous fragments made up of polygonal cells of the epicarp; endosperm tissue of cells containing aleurone grains and oil globules; fragments of oil glands and resin masses." *N. F.*

Juniper berries owe their medicinal virtues to a volatile oil. (See *Oleum Juniperi.*) The proportion of volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter Trommsdorff found 1 per cent. of the oil. In those perfectly ripe it has been partly changed into resin, and in those quite black, completely so. They are very largely consumed in the preparation of gin.

The tops of juniper were formerly directed by the Edinburgh and Dublin Colleges. Their odor is balsamic, their taste resinous and bitterish, and they possess similar virtues with the berries.

Uses.—The therapeutic properties of juniper berries are those of the volatile oil (see *Oleum Juniperi*). They are chiefly used as an adjuvant to the so-called alterative diuretics in the treatment of *cystitis* and similar complaints. For most purposes the oil is to be preferred. An infusion made by macerating an ounce of the bruised berries in a pint of boiling water is sometimes employed.

Dose, one drachm (4 Gm.).

Off. Prep.—Fluidextractum Juniperi, *N. F.;* Fluidextractum Buchu Compositum, *N. F.;* Elixir Buchu Compositum, *N. F.;* Elixir Buchu, Juniperi et Potassii Acetatis, *N. F.*

KALADANA. Br.

KALADANA [Semen Pharbitidis, Pharbitis Seeds]

"Kaladana consists of the dried seeds of Ipomœa hederacea, *Jacq.*" *Br.*

Closely allied to *Ipomœa hederacea* is *I. muricata,* the seeds of which are largely imported into Bombay, from Persia, under the name of *tukm-i-nil.* The juice of this plant is employed to destroy bedbugs, and the seeds are said to be identical in their medicinal properties with those of the official plant.

Ipomœa hederacea Jacq. (*I. cœrulea* Kon.; *Pharbitis Nil,* Choisy) is a twining annual plant belonging to the *Convolvulaceæ.* It has large blue flowers whence the specific name *Nil* which signifies, in Hindustani, blue. The leaves are three-lobed and the plant, while common throughout India, is found throughout the tropical regions of both hemispheres. Flückiger found it to contain 8.2 per cent. of resin which corresponded in its various properties to the resin of jalap.

Kaladana seeds are in the form of the segment of a sphere, black, somewhat hairy, weighing from one-half drachm to nearly one drachm. They are described by the British Pharm., 1914, as follows: "Seeds in the form of a segment of a sphere; usually about five millimetres long, but sometimes much smaller; nearly black. In transverse section, minute dark resin-cells in the plaited cotyledons. Slight odor; taste acrid." *Br.*

According to Kassner (*In. Dis.,* London, 1924) the term "Kaladana" signifies black seed in Hindustani and is applied in India to a number of unrelated seeds including, besides that official, those of the *Peganum Harmala* L. (*Rutaceæ*), the *Ocimum Basilicum* L. (see Part II) as well as other species of *Ipomœa.*

He has made an elaborate study of the histology of the seeds of *Ipomœa hederacea* and of the *I. muricata* Jacq. which are often substituted for the official. The most important diagnostic feature is the epidermis; the official seeds may be distinguished from all the others by the characteristic shape of the wavy walls and the dimensions of the epidermal cells in surface section and by the presence of sparsely scattered diagnostic trichomes of a restricted size.

Kassner found these seeds to contain about 15.7 per cent. of crude resin and about 12.4 per cent. of fixed oil. He found also indications of a saponin and of glucosidal matter. The true resin of kaladana he believes is non-glucosidal. He found that in doses of four grains (0.25 Gm.) this resin produced copious purgation, but that the glucosidal material even in double this dose had no effect. The resin as prepared by the official process is a mixture of the active and inert resinous material. What he calls the true resin was obtained by extracting with alcohol seeds which had been previously exhausted with acetone. The material so obtained he states is not convolvulin.

For literature on the subject of kaladana see Kassner's paper.

Uses.—Kaladana seeds were used by the Arabian physicians, under the name of *Habbun-nil,* and have been recommended as a safe and active cathartic by various English physicians resident in India. Their action is probably similar to that of jalap.

Dose, thirty to forty-five grains (2–3 Gm.).

Off. Prep.—Kaladanæ Resina, *Br.;* Pulvis Kaladanæ Compositus, *Br.;* Tinctura Kaladanæ, *Br.*

KALADANÆ RESINA. Br.

KALADANA RESIN [Pharbitisin]

"Kaladana Resin is a mixture of resins obtained from Kaladana." *Br.*

The resin is prepared from Kaladana by a process similar to that employed in isolating the resin from jalap. It is as follows: "Exhaust coarsely powdered Kaladana with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash with Distilled Water, and dry at a gentle heat." *Br.*

It is officially described as "in brownish, opaque fragments, translucent at the edges; brittle, breaking with a resinous fracture; readily reduced to a grey powder. Somewhat disagreeable odor, especially when warmed; taste sweetish, acrid. Readily soluble in *alcohol* (90 per cent.); almost insoluble in *benzene, ether, chloroform,* or *carbon disulphide.* When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide,* boiled for a few moments and cooled, when acidified with *hydrochloric acid,* may become opalescent but not immediately turbid (absence of certain other resins)." *Br.*

For further information about this resin see under *Kaladana.* It is used as cathartic.

Dose, two to eight grains (0.12–0.5 Gm.).

KAOLINUM. N. F., Br.

KAOLIN

"A native hydrated aluminum silicate, powdered, and freed from gritty particles by elutriation." *N. F.*

"Kaolin is a native aluminium silicate, powdered, and freed from gritty particles by elutriation." *Br.*

Terra porcellanea; Porcelain Clay, Bolus Alba; Terre à porcelaine, *Fr.;* Porcellanerde, Porcellanthon, *G.*

The term "clay" is applied rather loosely to various forms of earth which with water form more or less tenacious and plastic masses. The clays, which appear to owe their origin to the decomposition of rocks, are to be sharply distinguished from diatomaceous earth which is composed of the mineral constituents of microscopic algæ (see *Terra Silicea Purificata*); they differ not only in their physical properties, but also in their chemical composition. The clays proper have for their basis aluminum silicate and contain various quantities of sand, alkaline earths and other ingredients. Various forms of clay have been used in the arts and in medicine and are denominated by adjectives derived from the purpose for which they are employed. Kaolin or *china clay* is a hydrated aluminous silicate; *pipeclay* is a very white substance containing a somewhat larger percentage of silica; brick clay contains sand and some ferruginous material to which it owes its color. *Fuller's earth* is a non-plastic form of clay, so-called because of its use in fulling cloth. *Shale* is a clay rock which tends to split into thin lamina; *marl* is a clay which contains a large amount of calcareous matter with some potassium and phosphate. *Terra Sigillata* was a form of clay from Asia Minor once so highly esteemed that its production was only permitted under governmental authority and it was sent to the market in masses each bearing the imprint of the seal of the authorities; hence the name.

Nearly all of the clays will absorb a considerable amount of water, but some of them in addition have the power of *ad*sorbing solid constituents; that is they will remove dissolved substances from solution. By virtue of this adsorbtive power they may act as decolorizing agents and will also remove many alkaloids and apparently even bacterial toxins from aqueous solutions. To what this adsorbing power is due is, at present, somewhat obscure although it appears to be in part dependent upon the colloidal nature of the earth. *Lloyd's reagent* is a form of clay which has an extraordinarily high adsorptive property. On account of this adsorptive power for active principles and vegetable colors, clays should never be used as filtering or clarifying mediums without some preliminary experiments to determine the effect upon the finished preparation which is likely to be rendered inert.

Because of its property of absorbing large amounts of liquid, fuller's earth is used for many pharmaceutical purposes, especially in the preparation of pills. Fantus (*J. A. M. A.,* 1915, lxiv, p. 1838) has shown that there is considerable difference in the adsorbing power of various substances sold under the name of fuller's earth. (See also Jensen, *P. J.,* 1920, cv, 97.)

Kaolin, $Al_2(SiO_3)_3 + Al_2O(OH)_4$, occurs in abundant deposits as a decomposition product of felspar; the latter is a double silicate of aluminium and alkali, and in its weathering, the alkali is gradually eliminated. A pure kaolin contains approximately 47 per cent. of silica, 40 per cent. of alumina, and 13 per cent. of water.

Thomas J. Keenan, in an interesting article in the *Am. Drug.,* 1914, p. 55, gives a history of kaolin and its uses and points out the uncertainty of the product, due to the loose application of the name and proposes that the name be restricted to a compound having the composition $H_2Al_2Si_2O_8 + H_2O$.

Pure kaolin is almost infusible, but the presence of impurities, notably undecomposed felspar, increases its fusibility greatly. On the other hand, fire clays which are infusible are kaolins containing a considerable amount of free silica.

Large deposits of kaolin have been recently opened in Florida. It is now used extensively for clarifying oils, such as lard and cotton seed oils and mineral lubricating oils.

Description and Physical Properties.—"Kaolin occurs as a soft, white or yellowish white powder, or in lumps, insoluble in water, and in cold dilute acids and solutions of the alkali hydroxides. It has an earthy or clay-like taste. When moistened with water, Kaolin assumes a darker color and develops a marked clay-like odor.

"Mix 1 Gm. of Kaolin with 10 cc. of distilled water and 5 cc. of sulphuric acid in a porcelain dish; no effervescence occurs. Evaporate the mixture until the excess of water is removed, and further heat the residue until dense white fumes of sulphuric anhydride appear, then add 20 cc. of distilled water, boil for a few minutes and filter; there remains on the filter a gray residue of impure silica. To one-half of the filtrate just obtained add ammonia water; a gelatinous precipitate of aluminum hydroxide is obtained which is insoluble in an excess of the reagent. To a remaining half of the filtrate add sodium hydroxide T.S.; a gelatinous precipitate is produced which is completely or almost completely soluble in an excess of the reagent. Rub 2 Gm. of Kaolin in a mortar with 10 cc. of distilled water; the mixture does not acquire more than a slight reddish tint on the addition of 0.5 Gm. of sodium salicylate (*iron*). Ignite Kaolin at a red heat; not less than 85 per cent. of a non-volatile residue remains." *N. F.*

The British Pharmacopœia describes it as "a soft whitish powder, insoluble in *water,* or in diluted acids. When the product of its fusion with alkalies is digested with *water,* the filtered solution acidified with *hydrochloric acid,* evaporated to dryness, and the residue digested with *diluted hydrochloric acid,* a deposit of silica is obtained, and the supernatant acid solution yields the *reactions* characteristic of aluminium." *Br.*

Uses.—Various forms of clay have been used in medicine from time immemorial either as external or internal remedies. The value of these appears to reside in their absorbing properties, although there are some who attribute to them direct antiseptic action. There is no convincing proof of this assertion and the almost complete insolubility of clay renders it highly improbable. It is of service in various local infections, but its value in these conditions is generally explicable on mechanical grounds. It has been used with apparently good results in *suppurating wounds, tuberculous ulcers, weeping eczema, ozena, leucorrhea,* and similar conditions where its absorbent powers make it valuable. The claim is made that in many of these conditions because of its very fine pulverization it penetrates into the infected area and carries with it various antiseptics which may have been added. Rappaport (*J. A. M. A.,* 1916, lxvi, 943) reports that the application of thoroughly dried and finely powdered kaolin is useful for the removal of *diphtheria* bacilli and other bacteria from the throat and nose. It has been used internally in *Asiatic cholera* (see Walker, *L. L.,* Aug. 6, 1921), *gastro-enteritis,* and *dysentery.* Its effects in the latter conditions are probably those of a protective to the mucous membrane. Its virtues in these conditions appear to be due in part to the adsorption of the irritant secretions, and in part to its protective influence upon the mucous membrane. According to Hess (*J. A. M. A.,* 1916, lxvi, p. 106), fuller's earth surpasses either bismuth or chalk in lessening diarrhea. Probably by the formation of colloidal compounds it delays the absorption of toxic alkaloids from the alimentary tract, and Fantus has shown that it is an effective chemical antidote in the treatment of *strychnine poisoning.* While the adsorption of some alkaloids is delayed more than others, it probably has a wide field of usefulness in poisoning. (See also Clowes and Walters, *J. A. M. A.,* 1920, lxxv, 655.)

Kaolin is also widely used in the form of the cataplasm (see *Cataplasma Kaolini*) as a carrier of heat and moisture in various local inflammations instead of poultices. It is also recommended because of its mechanical properties as an aid in cleansing the hands of the surgeon. Kaolin is not easily affected by most chemical reagents, and it forms a good diluent or excipient for silver nitrate, potassium permanganate, or other salts which are decomposed by organic substances.

Dose, one-half to two ounces (15.5–60 Gm.) several times a day.

Off. Prep.—Cataplasma Kaolini, *N. F.*

KAVA. N. F. (Br.)

KAVA [Methysticum, Kava Kava]

"Kava consists of the dried rhizome and roots of *Piper methysticum* Forster (Fam. *Piperaceæ*). Kava contains not more than 1 per cent. of foreign organic matter." *N. F.*

"Kava Rhizome is the peeled, dried, and divided rhizome of Piper methysticum, *Forst. fil.*" *Br.*

Kavæ Rhizoma, *Br.;* Kava Rhizome.

The genus *Piper* includes a large number of sub-tropical plants, which are mostly shrubs, and rarely herbs or trees. A number of the species are of great economic importance. *Piper methysticum* is a shrub, several feet high, indigenous to many of the South Sea Islands. The plant has cordate, acuminate leaves and very short axillary spikes of flowers. The natives prepare a fermented liquor from the upper portion of the rhizome and the base of the stems.

Description and Physical Properties.—"*Unground Kava.*—Consisting of a large, irregular knotty crown, often 12 cm. or more in diameter, from which proceed numerous, long, cylindrical, tough, nearly simple roots, which tend to fray out into bare, separated fibrovascular bundles; sometimes cut into irregular angular pieces; the crown soft, light, spongy, and granular and very starchy; externally dark brown or blackish, the crown frequently partly scraped and light brown to light gray; internally white. Odor faint but characteristic; taste aromatic and pungent, slightly bitter, more or less local anæsthesia resulting.

"*Powdered Kava.*—Whitish; exhibits numerous, simple, or 2- to 3-compound starch grains, the individual grains being up to 0.045 mm. in diameter, many with radial clefts or triangular fissures at the center; yellow resin and oil cells; narrow sclerenchymatous fibers with thin, strongly lignified walls; tracheæ with scalariform or reticulate markings, up to 0.150 mm. in width;

few nearly isodiametric wood parenchyma cells from the remains of the stem." *N. F.*

The Br. describes it as "in whitish or light brownish-grey irregularly cuboid or roughly wedge-shaped fragments from which the periderm has been sliced off; from one to five centimetres thick. In transverse section, usually exhibiting a central dense pith, surrounded by a distinct ring of narrow, radiating, vascular bundles separated by relatively broad, paler, medullary rays. Fracture starchy. Slight agreeable odor; taste pungent and bitter." *Br.*

The pharmacognosy of this drug has been written up by Semenow in *Ap. Ztg.*, 1890. Hoffstadt has made an extensive study of the stem anatomy of *Piper methysticum.* She finds that it contains peripheral and pith bundle systems, the latter in two rows, differing from *P. umbellata,* a Mexican species which possesses but one row of pith bundles and mucilage canals extending through the center of the stem (*A. J. P.*, 1916, p. 485). Powdered Kava consists of numerous starch grains which are either single or 2- to 3-compound, the individual grains having central radial clefts with triangular fissures varying from 0.006 to 0.035 mm. in diameter. The sclerenchymatous fibers have thin walls which are strongly lignified. The tracheæ have scalariform or reticulate markings. The oil cells frequently contain a yellowish resin. The drug should not yield more than 8 per cent. of ash. (See also True, *Ph. Rev.*, xiv.)

Constituents.—Gobley isolated from kava root a crystalline principle, *methysticin,* or *kavahin,* $C_{15}H_{14}O_5$, which is without odor and taste, and is probably inert. It is the methyl ester of p-piperonyl acetic acid, and when purified forms silky, lustrous needles melting at 138° to 139° C. Kavahin differs from piperin and cubebin in being colored red by hydrochloric acid, the red color fading on exposure to air into a bright yellow, and in being colored by strong sulphuric acid a purplish violet, which passes into green. In 1844 Morson discovered a greenish-yellow, strongly aromatic and acrid resin which he called *kawine.* Lewin (*A. J. P.*, 1886) separated it into two resins, of which the β-resin is greasy and of a reddish-brown color, appearing in mass almost black. This is less active than the α-resin, which is yellowish-brown, has the characteristic odor of the drug, is freely soluble in alcohol, and placed upon the tongue produces a burning sensation followed by local anesthesia. Borsche and Gerhardt (*Riedels Archives,* 1914, 50) report the presence of a glucoside, *yangonin.* Lavialle (*L'Union Pharm.*, Jan., 1889) claims to have obtained an alkaloid, *kavaine.* (See also *Proc. A. Ph. A.*, 1897, 564.)

Murayama and Mayeda have taken up the investigation of *kava acid* previously reported by Murakami, and find it to contain a methoxyl group and to have the formula $C_{15}H_{16}O_2$. Upon hydrolysis with alcoholic solution of potassium hydroxide it yields benzaldehyde and a substance having the composition $C_{14}H_{16}O_3$. From the mother liquor of *kava acid* they obtained a crystalline compound, $C_{14}H_{18}O_4$, melting at 102°, which they termed *beta kava acid.* Borsche and Roth (*B. Chem. G.*, 1921, liv, 2229) report kava acid as having the composition $C_{13}H_{12}O_3$, melting at 164° C. and believe it to be an isomer of *cinnamylodeneaceto-acetic acid.*

Uses.—Under the names of *Ava* or *Kava* the natives of the Sandwich Islands have used as an intoxicant a beverage prepared from kava rhizome. The intoxication is wholly unlike that caused by alcohol, being of a silent and drowsy character, accompanied by incoherent dreams, with great loss of muscular power, which is probably due to the action of kava resin upon the spinal cord.

The physiological action of kava and its resin has been investigated by L. Lewin (*Piper Methysticum,* Berlin, 1886), and David Cerna (*T. G.*, 1891). The phenomena which follow the hypodermic injection of the fluidextract of kava or of a solution of its resin are, anesthesia at the point of injection, followed, after absorption, by general paralysis, due to a direct action on the motor side of the spinal cord; the motor nerves and the muscles remain intact. The local anesthesia is due to a paralysis of the sensory nerve filaments and when the resin is brought in contact with the mucous membranes there is a burning pain, followed in time by a complete loss of sensibility, which is remarkably permanent, since Lewin found that from six to seven minims of a solution of kava injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass away for eight days. (*D. M. Ztg.*, Feb., 1886.) The action of the drug upon the circulation is subordinate to its nervous influence, but according to the experiments of Cerna it does stimulate the heart, although it decreases the number of pulsations by stimulating the inhibitory nerve centers. The same investigator found that at first it stimulates, afterwards depresses, and finally paralyzes the respiratory center. The insolubility and irritant action of kava resin has lessened its use as a practical local anesthetic.

As long ago as 1857 kava root was employed in the treatment of *gonorrhea,* and there is much testimony to its value both in the acute and the chronic form of the disease, as well as in *cystitis, vaginitis, leucorrhea, nocturnal incontinence,* and similar conditions of the genito-urinary tract. It is rather too stimulating to be suitable for acute conditions.

Under the name of *gonosan* a twenty per cent. solution of kava resin in oil of sandalwood is used internally in the treatment of *gonorrhea.* The preparation is marketed in capsules containing 0.3 Gm. of which two to four may be given several times a day. (For the methods of determining kava resins in this and similar preparations, see *Ph. Ztg.*, 1914, 284.)

Dose, of kava rhizome, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Extractum Kavæ Liquidum, *Br.;* Fluidextractum Kavæ, *N. F.*

KINO. U. S., Br.

KINO

"Kino is the dried juice obtained from the trunk of *Pterocarpus Marsupium* Roxburgh (Fam. *Leguminosæ*). Kino yields not less than 45 per cent. of alcohol-soluble extractive and not less than 80 per cent. of water-soluble extractive." *U. S.* "Kino is the juice obtained from incisions in the trunk of Pterocarpus Marsupium, *Roxb.*, heated to boiling and evaporated to dryness. Known in commerce as East Indian, Malabar, Madras, or Cochin kino." *Br.*

Gummi (s. Resina) Kino; Indian Kino, Malabar Kino; Kino de l'Inde, *Fr. Cod.;* Kino, *G.;* Goma quino, *Sp.*

The term kino or "kano" was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name, and some confusion and uncertainty still exist, in relation to the botanical and commercial history of the drug. We shall first consider the general properties of official kino, then the several varieties.

The official variety is that known commercially as *East India, Malabar, Madras,* or *Cochin* kino. It is the product of *Pterocarpus Marsupium,* a lofty tree growing upon the mountains of the Malabar coast of Hindostan and in Ceylon. It possesses alternate, imparipinnate leaves with 5- to 7-notched leaflets, pale yellow flowers and orbicular legumes, each containing one seed. The red juice of the kino tree occurs in rows of short cells, axially arranged in the inner bark. Vertical incisions with oblique ones running into them are made in the bark and the juice, upon flowing out, is collected in cups or other receptacles. It is evaporated in the sun to the consistency of a hard dark mass and broken into small fragments, in which condition it is packed in wooden boxes for exportation. The drug comes to the United States either direct from Bombay or through London.

From a communication by F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Farther India, and has been exported from Maulmain to Europe. It is produced by a tree called *Pa-douck,* which Christison recognized from a description furnished to him by Begbie, of Maulmain, as *Pterocarpus Marsupium,* so that this kino has the same origin as that from Malabar. *Pterocarpus indicus,* of the Mauritius Islands, where it is known as *sang-dragon,* also yields a red kino to commerce.

Description and Physical Properties.—"*Unground Kino.*—Small, brittle, angular fragments, usually less than 10 mm. in diameter, varying in color from dark reddish-brown to reddish-black; inodorous; taste very astringent; upon mastication coloring the saliva pink.

"*Powdered Kino.*—Dark red; in angular fragments, with a glass-like, conchoidal surface, the thinner pieces translucent, yellowish-red or brownish-red; upon mounting in water, the fragments become rounded and gradually disintegrate, leaving colorless, granular particles among which are rod-shaped bacteria and a very few cellular fragments; in an alcohol mount, the red color of the fragments deepens, the translucency increases, and the sharp angular outlines are preserved while solution takes place. An aqueous solution of Kino has a faint acid reaction, gives a dark green precipitate with ferric chloride T.S. and a reddish-violet color with an aqueous solution of an alkali.

"**Assay.**—Proceed as directed under alcohol-soluble extractive, and water-soluble extractive." *U. S.*

"In small, angular, glistening, opaque, reddish-black, brittle fragments; transparent and ruby-red in thin laminæ. Inodorous; taste very astringent. Almost entirely soluble in *alcohol* (90 per cent.), slowly and incompletely soluble in cold *water,* not less than 75 per cent. soluble in boiling *water,* the solutions being deep red in color. Almost entirely insoluble in *ether.* An aqueous solution (1 in 20) yields a voluminous reddish precipitate with dilute mineral acids, and, when largely diluted with *water,* a greenish-black precipitate with *T. Sol. of ferric chloride.* Ash not more than 2.5 per cent. In India and the Eastern Divisions of the Empire, Butea Gum (Buteæ Gummi) may be employed in making the official preparations for which Kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used." *Br.*

If in large masses, it may be reduced without difficulty into minute fragments. It is without odor, and has a bitter, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep red color to water and alcohol, but is nearly insoluble in ether. Cold water forms with it a clear infusion. Boiling water dissolves it more largely, and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept, it often gelatinizes, and loses its astringency. (See *Tinctura Kino.*) Edmund White made an investigation into the cause of the gelatinization of tincture of kino (*P. J.,* May, 1903), from which it appears that this phenomenon was due to the presence in the kino of an enzyme belonging to the oxydases, and that this enzyme may be destroyed by boiling, a belief which seems to be shared by the editors of the Br. P. which provides that the juice shall be heated to the boiling temperature before evaporation.

Constituents.—The therapeutic value of kino is due to the presence of *kino-tannic acid,* a non-glucosidal tannin that gives a green coloration with ferric salts. The proportion of this principle in a good quality of drug is between 70 and 85 per cent., although much lower figures have been reported.

Kino-red is a phlobaphene which results from the oxidation of kino-tannic acid. Apparently there is a ferment present in kino which produces this change, so that kino loses its astringent properties when kept, both its aqueous and alcoholic solutions becoming gelatinous and non-astringent. It is stated that if these solutions are previously heated to the boiling point, which would destroy any enzyme present, this change will not take place. There is present also a small amount of a colorless non-astringent principle called *kinoin* discovered by Etti, with the formula $C_{28}H_{24}O_{12}$. The subtraction of H_2O from this formula gives $C_{28}H_{22}O_{11}$ which is the kino-red and subtraction of another H_2O gives $C_{28}H_{20}O_{10}$, which is known as *dianhydride.* All of these substances are found in small quantities in the natural juice. (See Allen's *Commercial Organic Analysis;* also White, *P. J.,* 1903; and Gathercoal, *J. A. Ph. A.,* 1924, xiii, 103.) Small amounts of pyrocatechin and of protocatechuic acid have also been found in kino.

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Genuine kino is sometimes substituted by the extract of krameria. The latter is more brittle and dissolves more quickly in water.

Unofficial Kinos.—A number of astringent extracts, some from sources not related to the official kino, have from time to time been used in medicine. The more important of these are noted below.

African Kino.—The original kino employed by Fothergill is now known to be the product of a tree growing in Senegal, the *Pterocarpus erinaceus* of Lamarck and Poiret. A particular account of *P. erinaceus* and its concrete juice, with a figure, by W. F. Daniell, is contained in the *P. J.,* 1854. The importation of African kino has long ceased. In 1896, however, a consignment of African kino reached London. It was examined by E. M. Holmes (*C. D.,* 1896, 226). It is said to be still used by the Portuguese of Angola, under the name of *Sangue de Drago.* As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambinense,* was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black, but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep red astringent infusion.

West India or *Jamaica Kino.*—This is believed to be the product of the *Coccoloba uvifera* L. (Fam. *Polygonaceæ*), or *sea-side grape.* It grows in the West Indies and neighboring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent.

Although it has been many years since any large quantity appeared in our markets, it may occasionally be met. It is contained in large gourds, into which it was evidently poured while in a liquid or semi-liquid state, and then allowed to harden. When taken from the gourd it breaks into fragments of various sizes, upon an average about as large as a hazelnut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their color a dark reddish-brown approaching to black. They are, however, neither so glistening nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments, are easily pulverized, and yield a dull-reddish powder, considerably lighter colored than that of the East Indian variety. The West India kino is without odor, and has a very astringent, bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, although rather less than the East Indian variety, and colors the saliva red. According to Kremel (*A. J. P.,* 1883) it contains pyrocatechuic acid but no kinoin. Robert Bridges found that cold water dissolved 89 per cent., and alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature, as it appeared to be viscid, and very much impeded the filtration of the aqueous solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice.

South American or *Caraccas kino,* in appearance, taste, odor and other sensible properties closely resembles the West India variety. It is probable that they are derived from the same plant, as the *Coccoloba uvifera* grows as well upon the continent as in the islands. South American kino was found by Bridges to yield 93.5 per cent. to cold water, and 93 per cent. to alcohol; the want of a minute proportion of resinous matter in the South American kino is the only apparent difference between the two drugs.

Macaranga kino is obtained from *Macaranga Roxburghii* Wright, of the Deccan peninsula. It occurs in the form of odorless, tasteless tears or irregular masses. The tears have fibrous fractures and when immersed in water yield unravelling fibers giving the appearance of a sea anemone. According to Hopper, this kino yields from 6 to 15 per cent. of a peculiar tannin and is closely allied to Butea kino, from which it is distinguished by fibrous tears and the fact that it contains so much gum which swells without dissolving in water. (*P. J.*, lxvi, 616.)

Myristica Kino.—There has been produced in Southern India a kino consisting of smaller or larger angular pieces, of deep garnet color, in thin fragments, and having the general characteristics of Malabar kino; according to E. Schaer, it is a product of *Myristica malabarica,* of *M. fragrans,* and probably of other species of the genus. In all important respects these kinos are said to correspond with Malabar kino, but to be distinguishable by containing crystals of calcium tartrate. Myristica Kino is probably a distinctive product from the so-called *Syndai varnish,* a rich red fluid obtained from the *Myristica gibbosa* Hook. f., and employed in Assam as a varnish. This varnish is highly astringent and after exposure becomes perfectly impervious, the changes being due to the presence of a ferment or enzyme. As has been shown by D. Hooper (*P. J.,* June 20, 1903), Syndai varnish, if kept in corked bottles, gelatinizes in a few weeks.

Botany or *Blue Mountain kino* is obtained from *Angophora lanceolata* Cav. (Fam. *Myrtaceæ*) of Australia. *Colombo kino* is obtained from a number of species of *Angophora.* Hooper (*P. J.,* 1908, xxvii, 161) reports the occurrence of three new astringent plant juices or kinos. They are derived from *Jatropha Curcas,* from South Salem; *Xylia dolabriformis,* from Burma; and *Parkia insignis* ("*Myauk-tanyet*"), also from Burma.

Incompatibilities.—The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, mercuric chloride, and sulphuric, nitric, and hydrochloric acids. The precipitate with iron is of an olive or greenish-black color. The alkalies favor the solubility of kino in water, but essentially change its nature and destroy its astringency.

Uses.—Kino is powerfully astringent. In this country it is used chiefly in the treatment of *diarrhea,* not attended with febrile excitement or inflammation. It is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to chalk mixture. It is occasionally employed as a local application in *leucorrhea* and in *passive hemorrhages.* The infusion may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool; aromatics may be added, if deemed advisable. The dose of this infusion is a fluidounce (30 cc.). The proportion of alcohol in the tincture renders it frequently an unsuitable preparation.

Dose, eight to thirty grains (0.5–2.0 Gm.).

Off. Prep.—Pulvis Catechu Compositus, *Br.;* Pulvis Kino Compositus, *Br.;* Tinctura Kino, *U. S., Br.*

KOLA. N. F.

KOLA [Cola]

"Kola is the dried Cotyledon of *Cola nitida* (Ventenat) Schott and Endlicher, or of other species of *Cola* (Fam. *Sterculiaceæ*). Kola yields not less than 1 per cent. of caffeine, and contains not more than 1 per cent. of foreign organic matter." *N. F.*

Kola Nuts; Semen (Nuces) Colæ; Cola, *Fr. Cod.;* Noix de Gourou, Café du Soudan, *Fr.;* Kolanuss, *G.;* Gooroo Nuts; Bichy Nuts; Bissy Nuts.

The *Cola acuminata* Schott and Endlicher (*Sterculia acuminata* Beauv.) is a large tree, indigenous to Guinea in western tropical Africa. It is largely cultivated in the West Indies and South America for the sake of its seeds, the present commercial supply of these coming chiefly from the Western Hemisphere. The fruit consists of 5 woody follicles, each of which contain 1 to 3 large white or crimson seeds, the kernels of which deprived of their seed-coats have long been used by the natives of Africa as a caffeinic stimulant under the name of *guru nuts.* It is stated that the negroes of Brazil use the seeds of the *Sterculia chica* A. St. Hil. and of the *S. striata* A. St. Hil. for similar purposes. Considerable of the kola nut of commerce is obtained from *Sterculia nitida* Vent., a West Indian tree.

Other species which are employed by the natives of Africa include the *Cola astrophora* Warburg whose seeds are red, the *C. alba,* whose seeds are whitish, and the *C. vera* Schumann, which is perhaps a hybrid of the two latter, its seeds being sometimes red and sometimes white.

Three varieties of *kola nuts* are said to be the product of *Cola acuminata.* The most valuable, the kola of Sakhala, is the largest, and is of a white color. The kola of Kassi, of Siarra, and of Touté, is of medium size, red or white. The kola of Maninian is small and red. Of the white kola there are two varieties, one whitish, resembling the kola of Sakhala but smaller; the other more or less rose-colored and larger.

Description and Physical Properties.—"*Unground Kola.*—Irregularly plano-convex, broadly oval, or approaching circular in outline, from 2.5 to 5 cm. in length, heavy, hard and tough; brown with the outer surfaces slightly wrinkled, the inner surfaces lighter and smoother; edges slightly incurved and sharp. Odorless; taste slightly astringent.

"*Powdered Kola.*—Reddish brown; numerous starch grains, some of which show alteration, the normal grains up to 0.045 mm. in diameter, the smaller ellipsoidal or spherical, the larger ellipsoidal or irregularly oblong and occasionally with a protuberance on one side; many of the larger grains show lamellæ and a circular hilum or a fissure through the center; parenchyma cells numerous, about 0.065 mm. in diameter, with reddish brown walls.

"**Assay.**—Place 6 Gm. of Kola, in fine powder, in a suitable flask or bottle, add 120 cc. of chloroform and shake. Allow to stand five minutes, then add 6 cc. of ammonia water and shake the mixture continuously during one hour, or intermittently (see Proximate Assays, Type Process A) during two hours. Allow the mixture to stand over night, again shake intermittently during one-half hour, then allow the drug to settle. Decant, or filter off through a pledget of purified cotton, 100 cc. of the chloroformic liquid, representing 5 Gm. of Kola and evaporate it to dryness. Treat the residue with 10 cc. of weak (about 1 per cent.) sulphuric acid with the aid of a gentle heat, allow to cool, filter through a small filter into a separator, and wash the dish and filter with successive small portions of distilled water until no test for alkaloid is obtained by acidulating a few drops of the filtrate strongly with sulphuric acid and adding iodine T.S. Now add ammonia water until the liquid is distinctly alkaline to litmus, and completely extract the caffeine with successive portions of chloroform, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions, and dry the residue at 80° C. to constant weight. The weight is the amount of caffeine from 5 Gm. of Kola." *N. F.*

The so-called *male kola* is essentially distinct from kola, being said to be the fruit of a small tree, *Garcinia Kola* (Fam. *Guttiferæ* Heck.), and containing no caffeine. The fruit is oblong, about one and a half to three inches long and from three-quarters to one inch broad; it is trigonal in section with a readily removable thin testa of a reddish-yellow to dark brown color, covered by markings which resemble those on the seed coat of the nutmeg. It is bitter and astringent. In the section the microscope reveals a number of resinous masses surrounded by cells rich in starch.

The seeds of *Lucuma mammosa* Griesebach (Fam. *Sapotaceæ*), sometimes mixed with kola nuts, are recognized at once by their strong odor of prussic acid. Heckel and Schlagdenhauffen have observed the seeds of *Heritiera litoralis* Dryand (Fam. *Sterculiaceæ*) mixed with kola nuts. These *false kola nuts* contain no caffeine, and are nearly orbicular and flattened in shape, one of the fleshy, purplish-brown cotyledons being only half the size of the other. (*A. J. P.*, 1887, 446.)

Constituents.—The composition of kola has been frequently and thoroughly investigated, and conflicting reports have appeared in the literature concerning the principles which are present. The investigation by Heckel and Schlagdenhauffen (*P. J.*, 1883, xiv) reported caffeine 2.34 per cent., theobromine traces, protein 6.76 per cent., cellulose 29.83 per cent., ash 3.32 per cent., and undetermined amounts of fat, tannin, kola dextrose, gum, and coloring matter. These results were practically confirmed about ten years later by Uffelmann and Bomer, but in 1897 Knox and Prescott (*J. Am. C. S.*, xix, p. 63) made an investigation in which they showed that the caffeine existed partly in the free state and partly in combination as a tannate. The free caffeine they found to be present to the extent of 1.85 per cent. and the combined caffeine 1.78 per cent., and the total caffeine therefore was 3.64 per cent. They claimed that *kolanin* was a mixture of the tannates of caffeine and theobromine. Other authorities, working on the subject more recently, have suggested that *kolanin* is a mixture of *kola-red* and caffeine, and Tschirch states that kola-red is produced by a ferment existing in the fresh seeds and that this ferment is destroyed by heating to 80° C. for thirty minutes. Goris and Chevalier (*P. J.*, 1908, xxvi, p. 31) isolated a phenolic principle from fresh kola, which they named *kolatin*, C_8H_8O. This is present to the extent of less than 1 per cent. and yields kola-red on oxidation. Knebel (*A. J. P.*, 1892) finds kolatin to be a glucoside, which upon hydrolysis splits up into caffeine, glucose, and kola-red. It seems probable that the enzyme reported by Tschirch accomplishes this hydrolysis. Goris (*P. J.*, 1906, lxxvi) further asserts that the kolatin is physiologically active and that it disappears from the nuts on drying, which would explain the difference in the effects of kola upon the natives as reported by travellers and the results of European investigators.

Uses.—The effects of kola nuts as they appear in European commerce, is indistinguishable from that of the other caffeinic drugs. The experiments of Mosso (*A. I. B.*, xix) seem to demonstrate conclusively the inertness of kola-red.

Kola is about equivalent to guarana, tea, coffee, etc., and may be substituted for them. In *dose* of one hundred and fifty grains (9.8 Gm.) a day, A. Hudson (*T. G.*, ii) has found the nuts to act decisively in cardiac weakness.

Dose, one drachm (4 Gm.).

Off. Prep.—Fluidextractum Kolæ, *N. F.*

KRAMERIÆ. U. S. (Br.)

KRAMERIA [Rhatany]

"Krameria is the dried root of *Krameria triandra* Ruiz et Pavon, known in commerce as Peruvian Rhatany, or of *Krameria argentea* Martius, known in commerce as Para or Brazilian Rhatany (Fam. *Leguminosæ*)." *U. S.*

"Krameria Root is the dried root of Krameria triandra, *Ruiz and Pav.* (Peruvian Rhatany), and also of another species of Krameria, probably Krameria argentea, *Mart.* (Pará Rhatany)." *Br.*

Krameria Radix, *Br.*; Rhatany Root, Radix Ratanhæ; Krameria Triandra, *Fr. Cod.*; Radix Ratanhiæ, *P. G.*; Ratanhiawurzel, *G.*; Ratania, *It.*, *Sp.*

This drug, dismissed from the U. S. at the ninth revision, has been re-admitted at the tenth.

The genus *Krameria* was named in honor of J. G. H. Kramer, a physician and botanist of Temesvar, Hungary. The name *rhatany* is said to express in the tongue of the Peruvian Indians the creeping character of the plant yielding the root.

Krameria triandra is a shrub, having a long, much-branched, spreading root, of a blackish-red color; with a round, procumbent, very dark colored stem, divided into numerous branches of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness of the young branches. The flowers are bright scarlet, and stand singly on short peduncles at the axils of the upper leaves. The stamens are three. The nectary is of four leaflets, the two upper spatulate, the lower roundish and shorter. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and having one or two seeds. It is a native of the Peruvian Andes, growing in dry argillaceous and sandy places. It flowers at all seasons, but is at the height of its bloom in October and November. The root is dug up after the rains, and, according to Tschudi, it is especially obtained in the southern provinces of Peru. Closely allied to it is *K. Ixina* L., which yields *Savanilla Rhatany.* It is, however, distinguished by having four stamens, and occurs in Guiana and northern Brazil. This variety was formerly recognized but was omitted from the U. S. X because it is not commercially obtainable.

Para or *Brazilian Rhatany* was described by Berg in 1865, and is believed to be the root of the *K. argentea* Martius. It closely resembles the Savanilla variety. Two forms of rhatany which Cotton has described as *Black* and *Brown Antilles rhatany*—because produced in these islands—have been pronounced by Flückiger (*P. J.,* July, 1870) to be identical with the Para Rhatany. According to the studies of Dunwoody (*A. J. P.,* 1890), this rhatany contains the same active principles as the root of *K. triandra,* but in slightly less quantity.

Peruvian Krameria is shipped to the U. S. A. from Peru; Brazilian or Para Krameria from Para and Rio de Janeiro, Brazil. During 1924, 1500 pounds of Krameria were imported into this country from Hamburg, Germany.

Description and Physical Properties.—"*Unground Peruvian Rhatany.*—Crown knotty, several- to many-headed, with numerous branching roots; the latter up to 50 cm. in length and usually less than 1 cm. in thickness, cylindrical or somewhat tapering, flexuous or wavy, externally light reddish-brown or brownish-red, more or less marked with darker scaly cork especially in the upper portion, somewhat longitudinally wrinkled but devoid of transverse fissures; fracture of bark slightly fibrous, of wood tough and splintery; the bark pinkish-brown internally and less than one-third of the radius, the wood yellowish or pinkish-white and finely radiate; inodorous; bark astringent, wood nearly tasteless.

"*Unground Para Rhatany.*—Roots usually separate from the crown, less flexuous, tapering, tough and internally darker in color than those of Peruvian Rhatany, and usually not exceeding 12 mm. in thickness; externally purplish-brown or chocolate-brown and marked with numerous fissures; the bark about two-fifths or more of the radius.

"*Powdered Krameria.*—Reddish-brown; starch grains single or 2- to 4-compound, the individual grains spherical, ellipsoidal, or plano-convex, sometimes with a central, radial, or star-like cleft, and from 0.003 to 0.035 mm. in diameter; bast-fibers more or less wavy in outline with very much attenuated ends and with non-lignified walls; tracheæ with simple or bordered pores associated with numerous wood-fibers which are narrow, spindle-shaped and with thick, porous, slightly lignified walls; numerous cellular fragments with yellowish- or reddish-brown walls; calcium oxalate in monoclinic prisms, from 0.010 to 0.100 mm. in length, and occasionally in spherical microcrystals." *U. S.*

The British Pharmacopœia recognizes two varieties of rhatany, which are described as follows: "Peruvian Rhatany is nearly cylindrical, slightly flexuous, reddish-brown; length variable; thickness not exceeding fifteen millimetres. Cork scaly; fracture splintery; wood yellow. In transverse section, bark bright reddish-brown and occupying about one-third of the radius of the section. Pará Rhatany is cylindrical, nearly straight, dark purplish-brown or almost black, and marked with deep transverse cracks. Fracture short; wood pale reddish-brown. In transverse section, bark dark reddish-brown and occupying about one-half of the radius of the section. Both varieties inodorous; taste of the bark astringent, of the wood scarcely perceptible. Ash not more than 4 per cent." *Br.*

Spurious rhatanys of unknown botanical origin have been reported by Holmes (*P. J.,* 1903, lxxvi, 878) and by P. H. Marsden, *P. J.,* 1901, 618.

According to an analysis made in the University of Wisconsin, the *Krameria lanceolata* Torrey, of North America, yields 34.5 per cent. of extract and 17 per cent. of tannin, and is therefore richer than the official drug. When treated with iron it strikes a deep-purple color, and is thus easily distinguished from Para rhatany, which gives a dirty brown color, and from Savanilla rhatany, which gives a violet color.

Payta krameria, which comes from Chile, is said to be the product of *K. cistoides.*

Constituents.—Krameria contains tannic acid, lignin, and minute quantities of gum, starch, saccharine matter, and an acid named *krameric* (or *rhatanic*) *acid.* The tannic acid of rhatany (*kramerio-tannic* or *ratanhia-tannic acid*), of which the root contains about 8 or 9 per cent., gives a dark-green precipitate with ferric chloride, a flesh-colored one with gelatin, and none with tartar emetic. In the presence of potassium hydroxide, it is transformed into protocatechuic acid and phloroglucin, and with diluted acids gives glucose and a red phlobaphene called *rhatany-red,* $C_{26}H_{22}O_{11}$.

In examining a specimen of extract of rhatany from America, Wittstein discovered an alkaloid *rhatanine* which he thought to be identical with tyrosine. Goldschmidt has shown (*D.

C., 1914, 17) that it is *N-methyltyrosine*, $C_{10}H_{13}O_3N$, and is identical with *angeline, geoffrayine* and *andirine* which have been described in various plants. He obtained it in crystalline needles, melting at 280° C.

Cold water extracts all the astringency of rhatany, forming a clear deep red infusion, which upon careful evaporation yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration, but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water, but this is owing to the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Krameriæ.*)

A very delicate test for the presence of rhatany is given by Glücksmann (*Ph. Post,* 1912, 65), who states that if an extract containing it be diluted with water until almost colorless, the addition of 0.5 Gm. of sodium bicarbonate to 10 cc. of the liquid will produce a rose red color.

Uses.—Rhatany is an active astringent, and may be advantageously given in *chronic diarrhea.* It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the *Peruvian Flora,* first made it known in Europe. In the form of infusion, tincture, or extract, rhatany has been used locally in *fissure of the anus, prolapsus ani,* and *leucorrhea.*

Dose, of the powder, fifteen to thirty grains (1–2 Gm.).

S.;* Trochiscus Krameriæ (from Extract), *Br.;* Trochiscus Krameriæ et Cocainæ (from Extract), *Br.;* Fluidextractum Krameriæ, *N. F.;* Fluidglyceratum Krameriæ, *N. F.*

LACTOSUM. U. S.

LACTOSE Lactos. [Saccharum Lactis, U. S. P. IX, Milk Sugar]

"A sugar [$C_{12}H_{22}O_{11}.H_2O$] obtained from cow's milk." *U. S.*

"Milk Sugar is a crystallized sugar, $C_{12}H_{22}O_{11},H_2O$, obtained from the whey of milk." *Br.*

Saccharum Lactis, *Br.;* Sugar of Milk; Lactin; Sucre de Lait, *Fr.;* Milchzucker, *G.;* Lattioso, Zucchero di latte, *It.:* Azucar de leche, Lactosa, *Sp.*

Preparation.—Sugar of milk is found in milk of which it forms about 5 per cent. (Boussingault). It is manufactured largely in Switzerland and the Bavarian Alps, especially from the whey left over in cheese making. Within recent years the numerous "creameries" in the United States have produced milk sugar in such large quantities as a by-product that its importation from Switzerland has almost ceased. The American method of manufacturing sugar of milk is described by LaWall (*Alumni Report Philadelphia Coll. Pharmacy,* April, 1902): The whey left after the first curding of the milk (by the separator system) is run into vats, and treated with about 1 per cent. of hydrochloric acid to remove coagulable protein, the liquid being heated to the boiling point, and exactly neutralized with calcium hydroxide. The whey is then generally filtered through a filter press and evaporated *in vacuo* to a thick syrup, run into pans, and allowed to stand for two days, when granular crusts form. These are then centrifuged and washed with cold water to remove calcium chloride and soluble impurities, and the washings are reserved for future operations. The crude milk sugar is of a very light yellow color, and has little taste or odor. It is redissolved in water and the solution filtered through bone black. The colorless syrupy percolate is concentrated *in vacuo* to a pasty mass, which is washed with cold water in a centrifugal machine. The mass is then dried on strainers in a drying chamber at 60° C., powdered in a ball mill, and bolted. The casein obtained by acidulation of the skim milk, and subsidence, is washed and heated with water containing a small amount of sulphuric acid, to remove impurities. The moist pulpy mass left after the removal of the water is then shredded by means of cutting knives run by a high-speed engine, the flakes being transferred to wire gauze frames and rapidly dried with a current of air at 140° F. It is then powdered with high-speed disintegrators. The soluble albumin, not coagulated by the acid treatment but subsequently coagulated by heat, has thus far not found any market although it could be produced in large amount if there were any demand for it, as its collection and purification would be a comparatively simple matter. See paper by England on American Milk Product Industry (*Proc. A. Ph. A.,* 1902, 354).

Description and Physical Properties.—"White, hard, crystalline masses, or a white powder, producing a gritty sensation on the tongue. It is odorless, and has a faintly sweet taste. It is stable in the air, but readily absorbs odors. One Gm. of Lactose is soluble in 4.9 cc. of water at 25° C., also in 2.6 cc. of boiling water. It is very slightly soluble in alcohol; insoluble in chloroform and in ether.

"The specific rotation $[\alpha]_D$ of Lactose determined at 25° C. in an aqueous solution containing in each 100 cc. 10 Gm. of Lactose, previously dried to constant weight at 80° C., and using a 200 mm. tube, is not less than +52.2° and not more than +52.5°, page 447. The solution must be allowed to stand overnight before observing the rotation. Add an equal volume of sodium hydroxide T.S. to 5 cc. of a hot, saturated, aqueous solution of Lactose, and gently warm the mixture: the liquid turns yellow and finally brownish-red. On the subsequent addition of a few drops of cupric sulphate T.S., a precipitate of cuprous oxide forms.

"An aqueous solution of Lactose (1 in 20) is neutral to litmus paper. Ash: not more than 0.1 per cent. A solution of 3 Gm. of Lactose in 10 cc. of boiling distilled water is clear, colorless, and odorless. Add 20 cc. of 70 per cent. (by volume) alcohol to 2 Gm. of finely powdered Lactose, shake the mixture frequently during half an hour at 15° C., and filter; a 10 cc. portion of the filtrate remains clear after mixing with an equal volume of dehydrated alcohol (*dextrin*), and this liquid upon evaporation on a water bath leaves not more than 0.03 Gm. of residue (*sucrose or glucose*). An aqueous solution of Lactose (1 in 20) meets the requirements of the test for *heavy metals.* Boil 1 Gm. of powdered Lactose with 50 cc. of distilled water, cool, and add a drop of iodine T.S.; no blue color is produced (*starch*).

"Preserve in tightly-closed containers." *U. S.*

"A white powder, or in crystalline masses; no odor, taste slightly sweet. Soluble in 7 parts of cold *water* and in about 1 part of boiling *water.* 5 grammes dissolved in *water* require for neutralisation not more than 1.5 millilitres of *N/10 solution of sodium hydroxide* (limit of acidity). When 5 grammes are well shaken with 20 millilitres of *alcohol* (90 per cent.) and filtered, the filtrate leaves no appreciable residue on evaporation (absence of sucrose). Ash not more than 0.25 per cent." *Br.*

In commerce sugar of milk frequently occurs in cylindrical masses, the axis of which is a wooden stick, around which the crystals have been deposited. Experiments have shown that much of the milk sugar of commerce contains micro-organisms which have resulted from the decomposition of animal constituents in milk, and the tests of the Pharmacopœias do not exclude such impurities. (*D. C.*, 1893, 250; *Bull. Pharm.*, 1893, v, 5; *P. J.*, 1894, 853.) Its specific gravity is 1.54. It is not susceptible of the vinous fermentation by the direct influence of yeast; but after hydrolysis by dilute acids, it is capable of furnishing a spirituous liquor by subsequent fermentation. It is well known that both mares' and cows' milk, after becoming sour, are capable of forming an intoxicating drink, by fermentation. By the action of nitric acid, lactose is converted into mucic acid. When anhydrous it consists of $C_{12}H_{22}O_{11}$; when crystallized, of $C_{12}H_{22}O_{11} + H_2O$. (Staedeler and Krause.) It is, therefore, isomeric with sucrose. Lactose, when treated with weak sulphuric acid, is inverted or changed into a mixture of *galactose,* and dextrose, both of the formula $C_6H_{12}O_6$. The galactose crystallizes in fine needles, fusing at 163° C.

J. W. England (*Proc. Penna. Pharm. Assn.*, 1915, p. 240) reported upon 17 lots of milk sugar, aggregating one-half million pounds, which showed a minimum purity of 99.73 per cent. by the polariscope with negligible traces of nitrogen, ash, and fat.

It is sometimes difficult to obtain lactose free from mechanical impurities introduced during handling. The special test for complete solubility is intended to guard against such impurities.

Uses.—Sugar of milk differs physically from cane sugar in the fact that it is less sweet. Because of its relative tastelessness it is sometimes preferred as an article of diet, especially in the feeding of infants, especially also, because it does not readily undergo the alcoholic fermentation. Its relation to metabolism is precisely the same as that of cane sugar except that the inversion into galactose takes place after its absorption and is probably accomplished by the epithelial cells of the intestines. Like other crystalloids when ingested in large quantities by modifying the osmotic relations of the blood it acts as a diuretic and has been practically used for this purpose by Germain Sée and others with advantage in the treatment of *cardiac dropsies.* If the kidneys be sound the lactose is said not to appear in the urine. It is used in doses of from 6 drachms to 6 ounces (23.5–186 grammes). It is used as a diluent in various official preparations.

LAC VACCINUM. N. F.

COWS' MILK

"The fresh, unpasteurized milk of the domestic cow, *Bos taurus* Linné (Fam. *Bovidæ*), without modification, and complying with the legal standards of the State or community in which it is sold." *N. F.*

Milk; Lait, *Fr.;* Milch, *G.;* Latte, *It.*

Milk, which is the secretion of the mammary gland of the mammalia provided for the nourishment of the young, is a natural emulsion containing proper proportions of nutritive constituents adapted for the particular species secreting it. Cows' milk is that most commonly used as food by man in civilized countries and is what is legally understood when the word "milk" is used unqualifiedly, but the milk of other animals is sometimes used. Among these may be mentioned the goat, sheep, llama, mare and reindeer.

The preference for cows' milk is a matter of custom determined largely by the fact that the hides and flesh of these animals are necessary to man, and by the naturally large volume of milk yielded which has been further augmented by selective breeding and scientific feeding.

Milk consists principally of water, casein and other proteins, fat, milk sugar, and mineral salts. Minute amounts of lecithin and nuclein, of enzymes and vitamines are also present and probably are of great value as nutritional factors. The proportion of the various ingredients in milk varies considerably, not only with the species of animal, but also, to a considerable extent, at different periods of lactation. Speaking in general terms, cows' milk contains a larger percentage of solid matters than human milk, although the latter is relatively richer in carbohydrate. The following table compiled from various authorities gives the approximate composition of human and bovine milk. One hundred parts contain:

	Water	Protein	Fat	Sugar	Ash
Human........	87-90	1.7-3.7	3.0-5.0	4.5-6.2	0.2-0.3
Cow........	84-87	3.7-4.5	3.5-6.0	4.3-5.0	0.6-0.7

Milk contains several proteins. *Casein,* the principal member of this group, is a phosphoprotein; albumin and a globulin-like protein are also present to a lesser extent and recently the presence of an alcohol-soluble protein has been announced. These four proteins have been shown to be immunologically distinct.

Tryptophane has also been shown to be present both in cows' milk and human milk.

The vitamines present in milk are the fat-soluble A and the antiscorbutic vitamine C. The latter is destroyed by heating and dried milk is deficient in this factor although not impaired in its growth-promoting vitamine.

The physical properties and composition of cows' milk are subject to a certain amount of variation due to the species of cattle, character and amount of food, time of milking, etc. The reaction of cows' milk, when fresh, is amphoteric, that is, alkaline to red litmus paper and acid to blue litmus paper. The specific gravity averages about 1.0315, but varies with the percentage of butter fat which, being a more concentrated emulsion, rises to the surface of the milk as cream, leaving below it a liquid containing very little fat but almost all of the casein, sugar and salts, and known as skim milk. Gravity cream, or cream which separates on standing, has been largely replaced by separator cream in which centrifugal force is applied to a stream of milk entering the device known as a separator, which continuously separates it into cream and skim milk, the relative richness of the cream and freedom of the skim milk from butter fat being regulated by the speed of the centrifugal motion. During recent years there has come into use an apparatus known as a homogenizer, in which the milk is subjected to the influence of great pressure and is at the same time forced through diaphragms containing minute perforations. The normal size of the fat globules, which is from 0.0025–0.0035 millilitres, is much reduced and the physical properties of the cream or milk are modified to such an extent that the subsequent separation of cream takes place much more slowly and the supernatant cream layer is bulkier and less rich in butter fat. The milk therefore appears richer to the eye judging from the apparent amount of cream which separates. The use of the homogenizer gives to cream which is to be used for ice cream manufacturing, properties which make for smoothness and higher quality of the resulting product. The homogenizer can also be used to combine butter with skim milk to make products simulating either cream or milk, depending upon the proportions of the ingredients. Fats normally foreign to milk, such as vegetable or animal oils, may be incorporated with skim milk by the use of this apparatus, and the resulting product used as a substitute for cream or milk. Such products are on the market usually under coined names, as they are frequently offered and sold in place of evaporated or condensed milk; their sale has been prohibited in some states, unless the label contains specific and plainly printed warnings that it is not to be used in infant feeding.

The normal decomposition of milk upon standing is accompanied by the development of lactic acid (the acid of sour milk) which is formed by bacterial action from the lactose (see *Lactic Acid*). Under some circumstances milk undergoes the butyric fermentation with the development of butyric acid from the fats of the milk. The alcoholic fermentation of milk is discussed under *Kefir* (which see).

Condensed or *evaporated* milk is milk which has had part of its water removed by evaporation in a vacuum apparatus. The concentration is usually two-fold, but in some instances is higher. Sweetened condensed milk is milk which has been concentrated by evaporation and to which has been added either cane sugar or invert sugar. So-called *"evaporated cream"* is frequently evaporated milk which has been concentrated to a higher degree than usual. There is a real evaporated cream on the market which contains nearly 70 per cent. butter fat. Milk may also be evaporated to the condition of a dry powder by the use of special forms of apparatus in which the effect of a vacuum is supplemented by distributing the milk in a very thin layer on a large metal cylinder or allowing it to escape into a very high vacuum or hot chamber in a very fine jet. *Powdered milk* may either be whole milk or skim milk. Both of these articles are now produced upon a very large scale for use in manufacturing confectionery, such as milk chocolate, and for combining in concentrated food products. Separated *milk fat,* free from the salt, curd and moisture which are present in butter, is also a commercial article, offered for special food manufacturing purposes.

Malted milk "is the product made by combining whole milk with the liquid separated from a mash of ground barley malt and wheat flour, with or without the addition of sodium chloride, sodium bicarbonate and potassium bicarbonate in such a manner as to secure the full enzymic action of the malt extract and by removing water. The resulting product contains not less than 7.5 per cent. of butter fat and not more than 3.5 per cent. of moisture."

Malted milk not only contains a higher percentage of carbohydrate, derived from the grain, but according to Ballard (*J. A. Ph. A.*, 1918, vii, 326), chemical change has taken place both in the carbohydrates and proteins through the action of the enzymes of the malt.

The U. S. minimum standards for these various forms of milk are as follows: Milk, 3.5 per cent. fat, 8.5 per cent. solids not fat; Cream, 18 per cent. fat; Evaporated milk, 34.3 per cent. milk solids and 7.8 per cent. fat (sweetened or unsweetened); Skim milk, 9.25 per cent. milk solids.

Some of the individual States have slightly different standards from the above U. S. standards, which apply only to milk shipped into interstate commerce.

The watering of milk is usually detected by the chemical analysis, a proportion of non-fatty solids less than 8.5 per cent., rendering the sample open to suspicion in this respect. The presence of added water is usually confirmed by taking the specific gravity of the milk serum or whey or by observing its refractive index by the use of an immersion refractometer. The freezing of the whey is another important factor in recognizing watered milk.

The use of preservatives in milk is universally prohibited and instances of such adulteration are now rarely met with. Among the preservatives, which were in more or less widespread use at one time, were formaldehyde, borax, salicylic or benzoic acid, fluorides and hydrogen dioxide. The latter preservative disappears within 48 hours by reduction to H_2O. Its use may be inferred, however, by the disappearance of the characteristic enzymes of milk, which may be readily determined by appropriate tests. It is the presence of these enzymes together with the vitamines, which are undoubtedly responsible for much of the value of milk as a food, apart from the fat, protein and carbohydrates present. It is of interest to note that in modern methods of milk concentration these enzymes are usually unaffected and remain in the finished product. Artificial coloring, such as annatto or coal tar colors are sometimes used in milk to give a false appearance of richness. They are prohibited by law and are easily detected by appropriate tests. Such crude methods of milk adulteration as the addition of starch or chalk or similar thickeners, have entirely disappeared. One method of increasing the viscosity or apparent richness of milk, the homogenizer or viscolizer as the machine is sometimes called, has already been referred to. Another method is by the addition of calcium sucrate which may readily be detected by specific reactions for sugar and excess of calcium in the ash.

Modern methods of milk control are concerned with the production of clean milk as well as pure milk. The bacterial count therefore plays an important part in judging of its quality. Standards vary in different localities, but the following is an example. In Chicago the milk, as it arrives in the city, it is limited to 1,000,000 bacteria per cc. from May 1 to September 1, and 500,000 per cc. during the remainder of the year. Municipal requirements for pasteurization usually reduce this figure to 50,000 per cc. when delivered to the consumer. *Certified milk* is required to be free from *B. tuberculosis* and to contain less than 10,000 bacteria per cc. (Class A), and 100,000 bacteria per cc. (Class B), without pasteurization.

As boiling milk is generally believed to lessen its digestibility as well as destroy its enzymes, the process known as *pasteurization* is employed to produce partial sterilization. For this purpose the milk is heated to a temperature of about 68° C. for from twenty to thirty minutes. This will destroy practically all the pathogenic bacteria likely to occur in milk without causing serious changes in its chemical composition.

Uses.—Any discussion of the value of milk as a food would trespass into fields foreign to the purpose of this work. Milk is of importance for more strictly medicinal purposes in two ways; as a vehicle it lessens the irritating effect of such drugs as iodides or salicylates upon the stomach. Recently it has been used hypodermically as a means of provoking the so-called protein reaction (see *Protein Therapy*, Part II). It is recognized in the National Formulary for the preparation of fermented milk. (See Part III; also *Kephir*, Part II.)

Off. Prep.—Lac Fermentatum, *N. F.*

LAMELLÆ.

DISCS

Gelatina Medicata in Lamellis; Medicated Gelatin Disks; Disques de Gélatine, *Fr.;* Gelatinlamellen, Gelatinplättchen, *G.*

Under this head are included in the British Pharmacopœia minute *gelatin discs* which contain traces of alkaloids, and which are designed to be inserted by oculists under the eyelid, in order to produce, through solution in the tears such effects as desired. A hot solution of gelatin containing the alkaloid in proper proportion is poured on a slightly greased or waxed glass or porcelain plate, cooled and dried, and then cut into discs, which, by previous calculation, will be found to contain the requisite quantity of medicament. A little glycerin is added to keep them from getting too hard and dry.

In Appendix X, British Pharmacopœia, a general formula is inserted as follows:

"*Process for Preparation of Discs* (*Lamellæ*), *Br.*—Discs are prepared by the following process:—Gelatin, 18 *grammes;* Glycerin, 2 *grammes;* Distilled Water, 88 *grammes.* Mix the Glycerin with the Distilled Water, allow the Gelatin to soak in the mixture till soft, and then dissolve by a gentle heat; cool the basis so produced. Take the prescribed quantity of the above basis, melt it by a gentle heat, add the prescribed quantity of medicament, dissolve and mix. Pour the melted and medicated basis upon a sheet of plate glass 10 centimetres square, previously thinly coated with White Beeswax, in such a manner that the solution is evenly distributed. Dry at a temperature not exceeding 36° C., and from the film thus obtained cut discs 3 millimetres (nearly ⅛ inch) in diameter."

LAMELLÆ ATROPINÆ. Br.

DISCS OF ATROPINE

Disques d'Atropine, *Fr.;* Atropinplättchen, *G.*

"Discs of Atropine are discs of Gelatin with Glycerin, each weighing about 1.3 milligrams (1/50 grain) and containing 0.013 milligram (1/5000 grain) of Atropine Sulphate. Prepare as directed in Appendix X, employing 0.016 gramme of Atropine Sulphate and 8.8 grammes of *basis.*" *Br.*

LAMELLÆ COCAINÆ. Br.

DISCS OF COCAINE

Disques de Cocaine, *Fr.;* Cocainplättchen, *G.*

"Discs of Cocaine are discs of Gelatin with Glycerin, each weighing about 3.5 milligrams (1/20 grain) and containing 1.3 milligrams (1/50 grain) of Cocaine Hydrochloride. Prepare as directed in Appendix X, employing 1.65 grammes of Cocaine Hydrochloride and 15 grammes of *basis.*" *Br.*

LAMELLÆ HOMATROPINÆ. Br.

DISCS OF HOMATROPINE

Disques d'Homatropine, *Fr.;* Homatropinplättchen, *G.*

"Discs of Homatropine are discs of Gelatin with Glycerin, each weighing about 2.1 milligrams (1/32 grain) and containing 0.65 milligram (1/100 grain) of Homatropine Hydrobromide. Prepare as directed in Appendix X, employing 0.82 gramme of Homatropine Hydrobromide and 10.1 grammes of *basis.*" *Br.*

Lucas (*C. D.*, 1899, 959) furnishes an improved formula for these discs; it is as follows: Gelatin, 30 gr.; Glycerin, 3 gr.; Distilled Water, 150 gr.; Homatropine hydrobromide, 10 gr. Dissolve and pour on to a waxed plate, so as to produce a film exactly 4 inches square. When dry, but still supple, punch out discs 1-7 inch diameter.

The product is about 784 discs, the remainder of the film being wasted. Each disc will weigh rather less than 1-20 gr. No inconvenience has been found in using discs weighing 1-15 gr., as, owing to their extreme tenuity, they soften as soon as they are inserted beneath the eyelid.

LAMELLÆ PHYSOSTIGMINÆ. Br.

DISCS OF PHYSOSTIGMINE [Discs of Eserine]

Disques d'Esérine, *Fr.;* Physostigminplättchen, *G.*

"Discs of Physostigmine are discs of Gelatin with Glycerin, each weighing about 1.3 milligrams (1/50 grain) and containing 0.065 milligram (1/1000 grain) of Physostigmine Sulphate. Prepare as directed in Appendix X, employing 0.082 gramme of Physostigmine Sulphate and 8.45 grammes of *basis.*" *Br.*

LAPPA. N. F.

LAPPA Lap. [Burdock Root]

"Lappa is the dried first year root of *Arctium Lappa* Linné, or of *Arctium minus* Bernhardi (Fam. *Compositæ*). Lappa contains not more than 5 per cent. of its leaf bases or more than 2 per cent. of other foreign organic matter." *N. F.*

Burdock Root; Radix Bardanæ; Bazzies; Beggars' Buttons; Cuckoo Button; Harebur; Bardane, Glouteron, *Fr.;* Klettenwurzel, *G.;* Bardana, *It.*

Although a native of Europe, burdock is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. There are three recognized species of *Arctium* in North America—viz., *A. tomentosum* (Lam.) Schk. (*Woolly* or *Cottony Burdock*); *A. Lappa* L. (*Burdock* or *Great Bur*); and *A. minus* Schk. (*Common Burdock*).

The stem of the burdock is succulent, pubescent, branching, and three or four feet in height, bearing very large, cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long petioles. The flowers are purple, with heads globose, and in terminal panicles. The involucre consists of imbricated scales, with hooked extremities, by which they adhere to the clothing of man and the coats of animals. The achenes are oblong, somewhat compressed and three-angled, ribbed, truncate.

Burnier (*Presse. Med.*, 1918) says that the drug must be gathered in the spring, that collected in the fall being inert.

Description and Physical Properties.—"*Unground Lappa.*—Nearly simple, fusiform, of variable length, from 5 to 20 mm. in diameter near the crown; frequently split or in broken pieces; externally grayish brown, longitudinally wrinkled, the crown somewhat annulate, sometimes surmounted by a wooly tuft of leaf remains; fracture somewhat horny; a dark cambium separating the thick brownish bark from the yellowish porous and radiate wood, centrally hollow or containing a white, pith-like tissue. Odor slight, becoming pyroligneous on milling; taste mucilaginous, sweetish, and slightly bitter.

"*Powdered Lappa.*—Light brown; exhibits parenchyma cells of the cortex, medullary ray cells and wood parenchyma containing amorphous masses or sphero-crystals of inulin; yellow resin cells from the cortical parenchyma of young roots; wood fibers few; starch and calcium oxalate absent." *N. F.*

The commercial supplies of Burdock root are obtained chiefly from Belgium and France. They are shipped in bags containing either the whole or cut root from Brussels, Antwerp and Marseilles to the United States.

Henderschott (*Proceedings of Mich. Pharm. Assoc.*, 1887) and also Trimble (*Ph. Era*, 1888, p. 133) have reported in the root a bitter, crystalline glucoside. Thos. Donaldson (*A. J. P.*, 1890, p. 123) found 8.6 per cent. of yellow fixed oil and about 1 per cent. of white waxy matter. A small quantity of volatile oil (0.065 per cent.) has been found in burdock root according to *Haensel's Report*, Oct., 1902. It also contains considerable amounts of inulin.

An interesting account of burdock and its use as an edible vegetable in Japan, by Inazo Nitobe, may be found in *A. J. P.*, 1897, 416.

Uses.—Burdock root has been employed as a diuretic and diaphoretic alterative, especially in the *gouty, scorbutic,* and *syphilitic* and *scrofulous diatheses;* also in various chronic skin diseases, especially in *psoriasis, prurigo* and *acne.* The fresh leaves have been employed both externally and internally in cutaneous eruptions and ulcerations. There is no sufficient reason, however, to believe it has any medicinal virtue.

Dose, thirty to ninety grains (2.0–5.8 Gm.).

Off. Prep.—Fluidextractum Lappæ, *N. F.*

LAUROCERASI FOLIA. Br.

CHERRY-LAUREL LEAVES

"Cherry-Laurel Leaves are the fresh leaves of Prunus Laurocerasus, *Linn.*" *Br.*

English Laurel, Cherry Bay; Laurier-cerise, *Fr.;* Kirschlorbeer, *G.;* Lauroceraso, *It.;* Laurel-cerezo (Hoja de), *Sp.*

Prunus Laurocerasus (Fam. *Rosaceæ*) is a small evergreen bush or tree indigenous to Southeastern Europe and Southwestern Asia but cultivated in temperate regions. It attains a height of 10 feet. It possesses long, spreading branches, which, with the trunk, are covered with a smooth, blackish bark. The leaves are oval-oblong, lanceolate, or oblanceolate, petiolate, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with two to four yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple, axillary or terminal racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry.

The leaves are packed in bales and shipped to the United States from Leghorn, Italy and Marseilles, France.

In their recent and entire state cherry-laurel leaves are devoid of odor; but, when bruised, they emit the characteristic odor of hydrocyanic acid and bitter almond oil. Their taste is somewhat astringent and strongly bitter, with the flavor of the peach kernel. They are officially described as "thick, coriaceous, on short, strong petioles, oblong or somewhat obovate, from twelve to eighteen centimetres long, tapering towards each end, recurved at the apex, distantly but sharply serrate and slightly revolute at the margins; dark green, smooth and shining above, much paler beneath; midrib prominent, with one or two glandular depressions on the under surface near its base. Inodorous, but emitting when bruised an odor resembling that of prussic acid." *Br.*

Cherry-laurel leaves are sometimes substituted by the leaves of other species of *Prunus.* These are readily distinguished in that they do not possess the characteristic glandular hairs which occur on the basal portion of the leaves and petioles of *P. Laurocerasus.* (*B. P. G.,* 1907, p. 325.)

Cherry-laurel leaves contain a glucoside formerly called *laurocerasin* but now known as *prulaurasin* which is isomeric with mandelonitrile glucoside, found in wild cherry bark, and related to amygdalin. They contain also a ferment, known as *prunase,* similar to, if not identical with, emulsin, which causes the decomposition of the glucoside and the formation of hydrocyanic acid and benzaldehyde. As the emulsin is stored in the veins and the prulaurasin found in the parenchyma of the leaf, the production of hydrocyanic acid takes place only after the leaves are broken. One pound, avoirdupois, of the fresh leaves yields 40.5 grains of a volatile oil which resembles that of bitter almonds.

Uses.—Cherry-laurel leaves are used chiefly as a flavoring agent similar to bitter almond especially in the form of the water. As Broker (*B. F. M. R.,* 1868) found that the proportion of hydrocyanic acid from the leaves varies with the season, age of the plant and the character of the soil and weather, they are inferior for this purpose to the oil of bitter almond. Several cases of prussic acid poisoning have been reported from their use. It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of so variable a remedy as the distilled water. (See *Aqua Laurocerasi.*)

Off. Prep.—Aqua Laurocerasi, *Br.*

LEPTANDRA. N. F.

LEPTANDRA Leptand. [Culver's Root]

"Leptandra consists of the dried rhizome and roots of *Veronica virginica* Linné (Fam. *Scrophulariaceæ*). Leptandra contains not more than 5 per cent. of its stem bases or other foreign organic matter and yields not more than 6 per cent. of acid-insoluble ash." *N. F.*

Culver's Root; Culver's Physic; Bowman's Root; Tall Speedwell; Tall Veronica; Black Root; Racine de Leptandra, ou de Véronique de Virginie, *Fr.;* Leptandra-Wurzel, *G.*

Veronica virginica is an herbaceous perennial, with a simple, erect stem, three or four feet high, smooth or downy, furnished with leaves in whorls, and terminating in a long spike of white flowers. The leaves, of which there are from four to seven in each whorl, are short-petiolate, lanceolate, pointed, and minutely serrate. A variety was seen by Pursh with purple flowers, which was described and figured as a distinct species by Rafinesque, under the name of *L. purpurea.* The plant flowers in July and August. It grows throughout the United States east of the Mississippi, affecting mountain meadows in the South and rich woods in the North, and is not unfrequently cultivated.

The rhizomes and roots are collected from plants of the second year's growth. The commercial supplies are largely obtained from North Carolina and southern Virginia.

Description and Physical Properties.—"*Unground Leptandra.*—Rhizome usually of horizontal growth, nearly cylindrical, somewhat branched; branches readily separable from the main rhizome, from 4 to 10 cm. in length and from 4 to 13 mm. in diameter; externally grayish-brown to dark reddish-brown; annulate from circular scars of bud-scales, upper surface with short stem remnants, occasionally with buds, and numerous circular stem-scars; from the under and lateral portions arise numerous coarse roots; fracture very tough and woody; internally, bark rather thin, dark brown and resinous, wood about the same thickness as the bark, light brown and porous, pith large, more or less hollow, the color being similar to that of the bark. Roots from 1 to 10 cm. in length and from 0.5 to 2 mm. in diameter; externally dark brown to purplish brown, smooth and faintly longitudinally wrinkled; fracture short; internally with a thick brownish black cortex and small light brown central cylinder. Odor characteristic; taste very bitter and acrid.

"*Powdered Leptandra.*—Brown to yellowish brown; consisting of numerous irregular fragments, many of them being colored pink or violet upon the addition of hydrated chloral T.S.; starch grains numerous, mostly in the parenchyma cells, the individual grains nearly spherical or more or less polygonal, up to 0.009 mm. in diameter; tracheæ with spiral thickenings or with simple or bordered pores; wood fibers with thick lignified walls, with simple pores or with bordered pores resembling tracheids; fragments of parenchyma containing a light brown or brownish-black resin, the latter frequently closely coherent with the starch grains in the cells thus preventing the separation of the individual starch grains; mounted in chloral hydrate T.S., occasional elongated cells with a lemon-yellow oily substance are observed." *N. F.*

For a microscopical description of leptandra, by A. P. Breithaupt, see *A. J. P.*, 1897, 235.

The active principle of leptandra is unknown. In 1856 E. S. Wayne reported the presence of a crystalline bitter substance which F. F. Mayer (*A. J. P.*, 1863) classed as a glucoside. Steinmann (*A. J. P.*, 1887) obtained a bitter principle which was neither glucosidal nor alkaloidal. On the other hand Power and Rogerson (*Tr. Chem. Soc.*, 1910, xcvii, p. 1944) were unable to obtain any substance corresponding to the earlier reports. They found in the plant about 6 per cent. of a brown resin from which they obtained a peculiar phytosterol, for which they proposed the name *verosterol;* dimethoxycinnamic and p-methoxycinnamic acids, and a brown amorphous substance, with an intensely bitter taste, amounting to about 1.6 per cent. of the drug. They believe that the crystals reported by Steinmann were probably dimethoxycinnamic acid contaminated with some of the bitter amorphous substance.

The substance sold under the name of "leptandrin" is an indefinite mixture made by adding water to a strong alcoholic tincture.

Uses.—Leptandra is a cathartic, in the fresh state acting rather violently, but when dried much milder. It is by some believed to have a special effect upon the liver and is used either as a substitute for or in conjunction with the mercurials.

Dose, fifteen to sixty grains (1–3.9 Gm.); of the impure resin, two to four grains (0.13–0.26 Gm.).

Off. Prep.—Extractum Leptandræ, *N. F.;* Fluidextractum Leptandræ, *N. F.;* Pilulæ Catharticæ Vegetabiles, *N. F.*

LIMONIS CORTEX. U. S., Br.

LEMON PEEL Limon Cort.

"The outer yellow rind of the fresh ripe fruit of *Citrus medica* var. *Limonum* (Risso) Hooker filius (Fam. *Rutaceæ*)." *U. S.* "Lemon Peel is the fresh outer part of the pericarp of the fruit of Citrus medica, *Linn.*, var. β Limonum, *Hook f.*" *Br.*

[*] Limonis Pericarpium; Ecorce (Zeste) de Citron, de Limon, *Fr. Cod.;* Cortex Citri Fructus, *P. G.;* Citronenschale, Limonenschale *G.;* Scorza di Limone, *It.*

For general remarks on the genus *Citrus,* see *Aurantii Cortex.*

Citrus medica, or lemon tree, closely resembles *Citrus Aurantium,* before described. Like the orange-tree it is a native of Asia. It is now known to grow wild in northern India, and was introduced into Europe from Persia or Media. It was first cultivated in Greece, afterwards in Italy, as early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air. The leaves, however, are larger, slightly indented at the edges, and their petioles are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is different in appearance from the orange. There are several varieties of *Citrus medica,* which some botanists consider as distinct species, but which scarcely differ except in the character of their fruits. Those particularly deserving of notice are the citron, lemon, and lime. 1. In the *citron, C. medica genuina,* the fruit is very large, sometimes six inches in length, ovoid, with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick and spongy. It is divided in the interior into nine or ten loculi, filled with small oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves to which it is adapted by its thickness. The fruit is called *cédrat* by the French. 2. The *lemon, C. medica* var. *Limonum* (*Citrus Limonum* of Risso), is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. (See *Succus Limonis.*) 3. The *lime* is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow color, and abounding in a very acid juice. It is the product of *C. medica acida.*

Description and Physical Properties.—"The outer lemon-yellow or dark-yellow layer, recently separated by grating or paring; consisting of the epidermis and numerous parenchyma cells containing yellow chromoplastids and large oil reservoirs with globules of the volatile oil; odor fragrant, distinctive; taste aromatic." *U. S.*

"Outer surface pale yellow and more or less rough; with only a small amount of the white spongy part of the pericarp on the inner surface; in transverse section numerous large oil-glands below the epidermis. Strong, characteristic and fragrant odor; taste aromatic and bitter." *Br.*

It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavor. Both this and the rind itself are recognized in the Pharmacopœias. (See *Oleum Limonis.*) When the white, spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited of a substance called *hesperidin.* This is a glucoside, and has the formula $C_{50}H_{60}O_{27}$, and is decomposed by diluted acids into *hesperetin,* $C_{16}H_{14}O_6$, and rhamnose. It turns dingy black when gently warmed with alcoholic solution of ferric chloride. It is bitter, but as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. E. G. Clayton has called attention to the distinction between lemon peel and orange peel when moistened by strong hydrochloric acid. Orange peel under these circumstances changes in color from a yellow to a rich dark green color, while lemon peel retains its hue or assumes a dingy yellowish-brown tint.

Uses.—The rind of the lemon is used to qualify the taste and increase the power of stomachic infusions and tinctures.

Off. Prep.—Tinctura Limonis, *U. S.* (*Br.*); Infusum Aurantii Compositum, *Br.;* Syrupus Limonis, *Br.*

LINIMENTA

LINIMENTS

Embrocations; Liniments, Embrocations, *Fr.;* Linimenta, Linimente, Einreibungen, *G.*

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand.

LINIMENTUM ACONITI. Br.

LINIMENT OF ACONITE

"Liniment of Aconite contains in 100 millilitres 0.2 gramme of the ether-soluble alkaloids of Aconite Root." *Br.*

Liniment d'Aconit, *Fr.;* Akonitliniment, *G.*

"Aconite Root, in No. 40 powder, 500 *grammes;* Camphor, Alcohol (90 per cent.), of each, *a sufficient quantity.* Moisten the Aconite Root with part of the Alcohol, pack in a percolator, and percolate with more of the Alcohol until the Root is exhausted. Reserve the first seven hundred and fifty *millilitres* of the percolate; evaporate the remainder to a syrup and add it to the reserved portion. Determine the weight of ether-soluble alkaloids in fifteen *millilitres* of the tincture thus obtained by the process described under 'Aconiti Radix.' Add to the remainder of the tincture sufficient of the Camphor and of the Alcohol to produce a Liniment of Aconite containing in 100 millilitres 0.2 gramme of the ether-soluble alkaloids of Aconite Root and 3 grammes of Camphor. Examined by the foregoing process Liniment of Aconite is found to contain in 100 *millilitres* 0.2 gramme of the ether-soluble alkaloids of Aconite Root. *Limit of error* 0.01 gramme in excess or defect." *Br.*

This preparation of the British Pharm., 1914, is now made of a definite strength through the introduction of an assay process. It is a very strong tincture of aconite root with camphor; that of the U. S. P., 1870, was almost equivalent to a fluidextract of aconite.

Uses.—Aconite liniment is counter-irritant and locally anesthetic. It may be applied alone by means of a camel's-hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. It must be used with caution lest sufficient aconite be absorbed through the skin to cause poisoning.

LINIMENTUM AMMONIÆ. Br.

AMMONIA LINIMENT Lin. Ammon.
[Volatile Liniment, Hartshorn Liniment]

Liniment of Ammonia, Linimentum volatile, Linimentum ammoniacale, *Fr. Cod.;* Savon ammoniacal, *Fr.;* Linimentum Ammoniatum, *P. G.;* Flüchtiges Liniment, Flüchtige Salbe, *G.;* Linimento ammoniacale, *It.;* Linimento amoniacal, *Sp.*

"Solution of Ammonia, 250 *millilitres;* Almond Oil, 250 *millilitres;* Olive Oil, 500 *millilitres.* Shake together." *Br.*

This useful liniment has been—unfortunately, according to our opinion—omitted from the U. S. X. It is recognized by the N. F. (see Part III).

The Br. preparation is made with almond oil and olive oil with the proviso that "In India, and in the Eastern, African, Australasian, and North American Divisions of the Empire, Arachis Oil or Sesame Oil, but no other oil or fat, may be employed in making the official Liniments, Plasters, Ointments, and Soaps for which Olive Oil is directed to be used." *Br.*

In this process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, with the added advantage of being relatively inexpensive, in *inflammatory joint affections* and in *rheumatic pains* and the like. It is applied by rubbing it, or placing a piece of flannel saturated with it, over the affected part. Should it occasion too much inflammation, it must be diluted with oil.

LINIMENTUM BELLADONNÆ. Br.

BELLADONNA LINIMENT Lin. Bellad.

Liniment of Belladonna; Liniment de Belladone, *Fr.;* Belladonnaliniment, *G.*

"Liquid Extract of Belladonna, 500 *millilitres;* Camphor, 50 *grammes;* Distilled Water, 100 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor in three hundred *millilitres* of the Alcohol; add the Liquid Extract of Belladonna, the Distilled Water, and sufficient of the Alcohol to produce the required volume. Set aside for twenty-four hours; filter." *Br.*

Belladonna liniment is an irrational preparation. It is highly improbable that applied in the manner of a liniment the belladonna penetrates the skin in sufficient quantities to have any effect, and it is difficult to understand what beneficial action could result if it did penetrate the skin. A solution of camphor and alcohol would be therapeutically equivalent to this liniment.

LINIMENTUM CALCIS. U. S., Br.

LIME LINIMENT Lin. Calc. [Carron Oil]

Liniment of Lime; Liniment calcaire, Savon calcaire, *Fr.;* Kalkliniment, *G.;* Linimento de calce, *It.;* Linimento Oleo-calcareo, *Sp.*

"Solution of Calcium Hydroxide, 500 cc.; Linseed Oil, 500 cc.; to make 1000 cc. Mix them by agitation." *U. S.*

"Solution of Lime, 500 *millilitres;* Olive Oil, 500 *millilitres.* Shake together." *Br.*

The lime forms a soap with part of the oil, the remainder of the oil then being easily emulsified by shaking, so that a thick creamy mixture results. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, which was originally used, but it possesses no other advantage than that of having a less unpleasant odor and of being somewhat less expensive.

This is an emulsion of the water in oil type, in which a calcium soap is the emulsifying agent.

The name of Carron oil was given to this emulsion from the fact that it was first employed at the Carron Iron Works in Scotland. For many years it has enjoyed a great popularity as an application in *burns* and *scalds.* The values claimed for it are that it relieves pain by excluding the air and tends to restore alkalinity to the burnt area. Many modern surgeons, however, object to this method of treatment on the ground that it makes it almost impossible to keep the injured area sterile.

LINIMENTUM CAMPHORÆ. U. S., Br.

CAMPHOR LINIMENT Lin. Camph. [Camphorated Oil]

"Camphor Liniment yields not less than 19 per cent. and not more than 21 per cent. of camphor. *Caution—This preparation is not intended for hypodermic use.*" *U. S.*

Liniment of Camphor, Linimentum Camphoratum; Huile camphrée, Liniment camphré, *Fr.;* Kampherliniment, Kampheröl, *G.;* Oleum Camphoratum, *P. G.*

"Camphor, in coarse powder, 200 Gm.; Cottonseed Oil, 800 Gm; to make 1000 Gm. Pour the cottonseed oil into a suitable dry flask or bottle, heat it on a water bath, introduce the camphor, and stopper the container securely. Dissolve the camphor by agitation without the further application of heat." *U. S.*

"Camphor, in flowers, 200 *grammes;* Olive Oil, 800 *grammes.* Dissolve the Camphor in the Olive Oil in a closed vessel." *Br.*

"**Assay.**—Place 5 cc. of Camphor Liniment in a tared, porcelain dish, having a diameter of about 75 mm., weigh accurately, heat at about 110° C. for ninety minutes, or until the odor of camphor is no longer discernible, cool, and weigh; the loss in weight is not less than 19 per cent. and not more than 21 per cent." *U. S.*

S. D. Wetterstroem prefers cold solution to the official method, thus avoiding any loss of camphor. (*West. Drug.,* 1897, 68.) For methods of assaying camphor liniment, see *C. D.,* 1900, 338; *P. J.,* 1898, 545; *P. J.,* 1902, 106; *Am. Drug.,* 1905, 345.

Uses.—This liniment is a very popular counter-irritant embrocation in *sprains, bruises, rheumatism, acute bronchitis,* and various other inflammatory states. Camphor liniment should not be confounded with camphorated oil of the German Pharmacopœia which is much weaker (1 in 10).

For fatal case of poisoning from swallowing this liniment, see Barker, *B. M. J.,* 1910, ii, p. 921. (See also under *Camphora.*)

The term "camphorated oil" is sometimes applied to a solution of camphor in olive oil intended for hypodermic use; the liniment of camphor must not be used for this purpose.

Off. Prep.—Linimentum Chloroformi, *Br.;* Linimentum Hydrargyri, *Br.;* Linimentum Terebinthinæ Aceticum, *Br.;* Ceratum Camphoræ, *N. F.*

LINIMENTUM CAMPHORÆ AMMONIATUM. Br.

AMMONIATED LINIMENT OF CAMPHOR

Compound Liniment of Camphor, *Br.;* Liniment ammoniacal camphré, *Fr.;* Linimentum Ammoniacale Camphoratum, *Fr. Cod.;* Linimentum ammoniato-camphoratum, *P. G.;* Flüchtiges Kampherliniment, Ammoniak- und Kampher-Liniment, *G.;* Linimento ammoniacale canforato, *It.;* Linimento amoniacal alcanforado, *Sp.*

"Camphor, 125 *grammes;* Oil of Lavender, 5 *millilitres;* Strong Solution of Ammonia, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor and Oil of Lavender in six hundred *millilitres* of the Alcohol; add the Strong Solution of Ammonia gradually, shaking frequently; finally add sufficient of the Alcohol to produce the required volume." *Br.*

This is inferior to the camphor liniment because the absence of a lubricant makes rubbing difficult.

LINIMENTUM CHLOROFORMI. U. S., Br.

CHLOROFORM LINIMENT Lin. Chlorof.

Liniment of Chloroform; Liniment au Chloroforme, *Fr. Cod.;* Chloroformliniment, *G.*

"Chloroform, 300 cc.; Soap Liniment, 700 cc.; to make 1000 cc. Mix them by agitation." *U. S.*

"Chloroform, 500 *millilitres;* Liniment of Camphor, 500 *millilitres.* Mix." *Br.*

A very great improvement was made in this preparation by the Committee of Revision of 1880, in the substitution of soap liniment for the olive oil. This change had been proposed in a previous edition of the Dispensatory, and it was desirable on account of the greasy residue which was left on the skin by the old preparation. The British Pharmacopœia has retained the oily vehicle. An accurate and expeditious method of assaying this liniment for its chloroform content is suggested by Jos. L. Mayer (*Proc. N. Y. S. P. Assn.*, 1912, p. 295), which consists in distilling the chloroform and collecting it in a graduated cylinder containing distilled water. The chloroform is measured when it ceases to come over and the calculation readily made. This is an excellent local application in painful affections. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full counter-irritant effect, to guard against this by using waxed paper, or some other impermeable covering.

LINIMENTUM CROTONIS. Br.

LINIMENT OF CROTON OIL

Linimentum Tiglii, *N. F. IV;* Liniment crotoné, *Fr.;* Krotonölliniment, *G.*

"Croton Oil, 120 *millilitres;* Oil of Cajuput, 440 *millilitres;* Alcohol (90 per cent.), 440 *millilitres.* Mix." *Br.*

This is a pustulating preparation, the irritant influence of which has been increased by the substitution of the oil of cajuput and alcohol for the olive oil of the original formula. From ten to thirty minims (0.6–1.8 cc.) may be rubbed upon a limited surface, and repeated twice a day or oftener until an eruption is produced.

LINIMENTUM HYDRARGYRI. Br.

LINIMENT OF MERCURY

Linimentum Mercuriale; Liniment mercuriel, *Fr.;* Quecksilberliniment, *G.*

"Ointment of Mercury, 50 *grammes;* Solution of Ammonia, 40 *millilitres;* Liniment of Camphor, 80 *millilitres.* Shake the Solution of Ammonia with the Liniment of Camphor, and triturate the Ointment of Mercury with the mixture. This Liniment contains approximately three-fifths of the proportion of Mercury contained in the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This is a stimulating liniment, employed for both its local and constitutional effects in *syphilitic pains,* in *glandular enlargements, swellings of the joints,* and to promote the absorption of fluid. It is said to be more likely to salivate than is mercurial ointment. One fluidrachm (3.75 cc.) may be rubbed upon the affected part night and morning. It should be thoroughly agitated before being applied.

LINIMENTUM OPII. Br.

LINIMENT OF OPIUM

Anodyne Liniment; Liniment opiacé, *Fr.;* Opiumliniment, *G.*

"Tincture of Opium, 500 *millilitres;* Liniment of Soap, 500 *millilitres.* Mix; set aside for a few days; filter." *Br.*

The use of this class of preparations is founded on error, as opium is not efficient as a local remedy.

LINIMENTUM POTASSII IODIDI CUM SAPONE. Br.

LINIMENT OF POTASSIUM IODIDE WITH SOAP

Liniment savonneux ioduré, *Fr.;* Jodkalium-Seifenliniment, *G.*

"Curd Soap, recently prepared and in shavings, 40 *grammes;* Potassium Iodide, 30 *grammes;* Glycerin, 20 *millilitres;* Oil of Lemon, 2 *millilitres;* Distilled Water, 200 *millilitres.* Mix the Curd Soap with the Distilled Water and Glycerin in a tared porcelain dish on a water-bath; when the Soap is dissolved make up to the original weight with Distilled Water; pour the liquid into a mortar containing the Potassium Iodide, previously powdered; mix briskly by trituration; continue the trituration until the mixture is cold, set aside for an hour; then add the Oil of Lemon, and again triturate the gelatinous product." *Br.*

This preparation is apparently intended, by application to the surface, which may be attended with a gentle friction, to produce the absorption of the iodide, an occurrence which in light of our present knowledge seems very improbable. The soap and glycerin act as demulcents, and thus obviate in some measure the local irritation of the salt.

LINIMENTUM SAPONIS. U. S., Br.

SOAP LINIMENT Lin. Sapon.

Tinctura Saponis Camphorata, *U. S.* 1850; Spiritus Nervinus Camphoratus; Camphorated Tincture of Soap; Liquid Opodeldoc; Liniment savonneux camphré, *Fr.;* Linimentum saponato camphoratum, *P. G.;* Flüssiger Opodeldok, *G.;* Linimento di sapone con canfora, *It.*

"Soap, dried and granulated, or powdered, 60 Gm.; Camphor, in small pieces, 45 Gm.; Oil of Rosemary, 10 cc.; Alcohol, 700 cc.; Water, a sufficient quantity; to make 1000 cc. Dissolve the camphor and the oil of rosemary in the alcohol, add the soap, and then sufficient water to make the product measure 1000 cc. Agitate the mixture until the soap is dissolved, set it aside in a cool place for twenty-four hours, and filter." *U. S.*

"Soft Soap, 80 *grammes;* Camphor, 40 *grammes;* Oil of Rosemary, 15 *millilitres;* Distilled Water, 170 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Soap, Camphor, and Oil of Rosemary in six hundred *millilitres* of the Alcohol; add the Distilled Water and sufficient of the Alcohol to produce the required volume; set aside for a week; filter." *Br.*

This process is intended to furnish a saturated solution of Castile soap. The improvement was made in the eighth revision of the U. S. P. of making a gelatinous mass of the soap by adding it to sufficient boiling water and heating it until dissolved; the soft mass easily dissolves in the alcoholic solution of the oils, but in the U. S. P. X retains the process of the ninth revision in which process the granulated or powdered soap is added to the alcohol and when the water is introduced solution occurs almost at once. The liquid should be cold before filtration to avoid precipitation in cold weather. The British preparation is now made with soft (potash) soap; this method was recommended by J. T. Hornblower. (*C. D.,* 1894, 571.) The liniment is said to be made more quickly and precipitation is avoided. Various other soaps have been recommended. (See *U. S. D.,* 20th ed., p. 621.)

Any pharmaceutical difficulty encountered in making a satisfactory preparation by the official formula can usually be attributed to the use of soap which is not in compliance with the official requirements.

The N. F. recognizes under the title *Linimentum Saponis Camphoratum* a semi-solid preparation which had a wide popularity under the name *opodeldoc.* (See Part III.)

Soap liniment is much used as a gently rubefacient embrocation, in *sprains, bruises,* and *rheumatic* or *gouty pains,* but is too feeble to exercise any pronounced effect. It is largely used as a vehicle for more active counter-irritants.

Off. Prep.—Linimentum Chloroformi, *U. S.;* Linimentum Opii, *Br.;* Linimentum Aconiti et Chloroformi, *N. F.*

LINIMENTUM SAPONIS MOLLIS. U. S.

LINIMENT OF SOFT SOAP Lin. Sapon. Moll.
[Tincture of Green Soap]

Tinctura Saponis Virdis, *U. S. P.* 1880; Spiritus Saponis Kalini Hebra; Teinture de Savon vert, *Fr.;* Hebra's Seifenspiritus, *G.*

"Soft Soap, 650 Gm.; Oil of Lavender, 20 cc.; Alcohol, a sufficient quantity, to make 1000 cc. Mix the oil of lavender with 300 cc. of alcohol, dissolve in this the soft soap by stirring or by agitation, and set the solution aside for twenty-four hours. Then filter it through paper, adding sufficient alcohol to make the product measure 1000 cc." *U. S.*

C. E. Smith suggested the preparation of this liniment from the fixed oil directly, which has the advantage of convenience as well as of greater uniformity of strength. (See *U. S. D.,* 19th ed., p. 698.) If a green color is desirable in this preparation, it may be obtained by using hemp seed oil or Malaga olive oil. (See *Proc. A. Ph. A.,* 1903, 420.)

LINIMENTUM SINAPIS. Br.

LINIMENT OF MUSTARD

Linimentum Sinapis Compositus, *N. F.;* Liniment Sinapisé composé, *Fr.;* Zusammengesetztes Senfliniment, Senfliniment, *G.*

"Volatile Oil of Mustard, 35 *millilitres;* Camphor, 55 *grammes;* Castor Oil, 125 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Dissolve the Camphor and the Oils in the Alcohol." *Br.*

The N. F. preparation differs from the Br. in containing fluidextract of mezereum in addition to the mustard oil and camphor (see Part III). It affords a convenient method of applying the volatile oil of mustard, and may often be appropriately used as a substitute for sinapisms. The castor oil seems to be added in order to increase somewhat the consistence of the liniment, and was probably chosen from among oleaginous substances in consequence of its solubility in alcohol. The effect is increased if the liniment be applied on flannel, and volatilization guarded against by covering it with oiled silk.

LINIMENTUM TEREBINTHINÆ. Br.

TURPENTINE LINIMENT

Linimentum Terebinthinatum; Liniment of Turpentine; Liniment térébenthiné, *Fr.;* Terpentinliniment, *G.*

"Soft Soap, 75 *grammes;* Camphor, 50 *grammes;* Rectified Oil of Turpentine, 650 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Mix the Soft Soap with one hundred *millilitres* of the Distilled Water; dissolve the Camphor in the Oil of Turpentine; gradually add the latter solution to the former, triturating until the mixture becomes a thick creamy emulsion; add sufficient Distilled Water to produce the required volume." *Br.*

More than a century ago a Doctor Kentish proposed for the treatment of *burns* a mixture of resin cerate and oil of turpentine; this was long known as *Kentish's ointment.* This was official in the first edition of the U. S. P. and remained practically unchanged through the ninth revision but was dropped from the tenth. The original formula, for some inexplicable reason, was changed in the 1867 revision of the Br. by the substitution of soft soap for the cerate and an increase in the proportion of the oil of turpentine. This change produced a preparation of entirely different therapeutic properties, more fitted for a counter-irritant liniment than for the treatment of inflammatory conditions of the skin. The present British preparation, so far as regards its rubefacient operation, may be looked upon as almost undiluted oil of turpentine, the soft soap having little other effect than to give consistence to the liniment, and the camphor acting as an anodyne, and both being too small in bulk to dilute the oil materially.

LINIMENTUM TEREBINTHINÆ ACETICUM. Br.

LINIMENT OF TURPENTINE AND ACETIC ACID

Linimentum Album; Acetic Turpentine Liniment, Stokes' Liniment; Liniment térébenthiné acétique, *Fr.;* Terpentin- und Essig-liniment, *G.*

"Glacial Acetic Acid, 110 *millilitres;* Liniment of Camphor, 445 *millilitres;* Rectified Oil of Turpentine sufficient to produce 1000 *millilitres.* Mix." *Br.*

Under this name the National Formulary (see Part III) contains a formula for *St. John Long's Liniment,* which unfortunately is not identical with the process of the British Pharm., 1914.

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment. Glacial acetic acid was substituted for acetic acid in the 1885 revision in equivalent proportion; the change is an improvement pharmaceutically, as it now affords a clear solution.

LINUM. U. S. (Br.)

LINSEED [Flaxseed]

"Linseed is the dried ripe seed of *Linum usitatissimum* Linné (Fam. *Linaceæ*). Linseed contains not more than 2 per cent. of other seeds or foreign organic matter, and yields not less than 30 per cent. of non-volatile ether-soluble extractive, at least 98 per cent. of which is saponifiable." *U. S.* "Linseed consists of the dried ripe seeds of Linum usitatissimum, *Linn.*" *Br.*

Lini Semina, *Br.;* Semence de Lin, *Fr. Cod.;* Grains de Lin, *Fr.;* Semen Lini, *P. G.;* Leinsamen, Flachssamen, *G.;* Lino, Semi di Lino, *It.;* Lino (Semilla de), Linaza, *Sp.*

Off. Prep.—Lini Semina Contusa, *Br.;* Species Emollientes, *N. F.*

LINI SEMINA CONTUSA. Br.

CRUSHED LINSEED

"Crushed Linseed is Linseed reduced to a coarse powder. It should be recently prepared." *Br.*

Linum Contusum, *Br.* 1898; Crushed Flaxseed.

Common *flax* is an annual plant, with an erect, slender, smooth stem, about two feet in height, branching at top, and bearing alternate, linear-lanceolate, sessile leaves. The flowers are terminal, and of a delicate-blue color. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells. This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of Central Asia. Its original home is unknown. It flowers in June and July, and ripens its seeds in August.

The flax plant was cultivated for its fiber by the American colonists soon after the landing of Columbus. Soon thereafter it was grown for its seed and already in 1792 the United States exported nearly 300,000 bushels of flaxseed. Very early the linseed oil industry was developed in the United States and in 1810 there were nearly 300 linseed oil mills in the 14 states, more than half of them being in Pennsylvania. It is estimated that at the present time 12,000,000 bushels of seed are crushed annually for the oil. The annual crop of flaxseed in the United States exceeds 30,000,000 bushels of which nearly one-half is produced in North Dakota. A large quantity of seed is annually exported as well as oil-cake, the latter being extensively used as a cattle food.

Description and Physical Properties.—"*Unground Linseed.*—Ovate or oblong-lanceolate, flattened, obliquely pointed at one end, from 4 to 6 mm. in length; externally brown, smooth and shiny; raphe a distinct yellow ridge along one edge, the hilum and micropyle in a slight depression just below the pointed end; internally light yellow or brownish, oily; odor slight; taste mucilaginous and oily.

"*Structure.*—Epidermis with a mucilaginous outer wall covered by a very thin, more or less broken sheath of cutin; two layers of parenchyma overlying a continuous layer of stone cells; a pigment layer, the cells having reddish-brown contents; endosperm of from 6 to 10 rows of cells, surrounding two large, plano-convex cotyledons, cells of cotyledons and endosperm containing a fixed oil and aleurone grains.

"*Powdered Linseed.*—Yellowish-brown; consisting chiefly of large, oil globules and irregular fragments of endosperm and seed-coat; seed-coat characterized by tabular pigment cells filled with reddish-brown insoluble contents and by the somewhat radially elongated stone cells with yellowish, porous walls and rather large lumina;

aleurone grains from 0.003 to 0.020 mm. in diameter.

"*Linseed Meal.*—Yellow with numerous brown fragments; the fragments of both seed-coat and kernel mostly very coarse and with the same cellular tissues as those of the powder.

"Boil 1 Gm. of fat-free Linseed Powder or Meal with 50 cc. of water, cool, and filter: the filtrate shows, upon the addition of iodine T.S., not more than a faint blue color (*starch or starch-bearing seeds*).

"**Assay.**—Proceed as directed under non-volatile, ether-soluble extractive, page 466, using 4 Gm. of ground or powdered Linseed. Treat the anhydrous extractive as directed under saponification value." *U. S.*

"Seeds small, brown, glossy, nearly flat; from about four to six millimetres long; ovate, somewhat obliquely pointed; surface glabrous and minutely pitted. Internally yellowish-white, with a narrow oily endosperm and two large oily cotyledons. Epidermal cells filled with mucilage which swells and dissolves in *water*. No odor; taste mucilaginous, oily." *Br.*

The linseeds in commerce have been divided by E. M. Holmes into two groups. The first group, characterized by the seeds being of sufficient size for six or seven to weigh a grain, contains Bombay, Bold Calcutta, Sicilian, and Ionian seed; in the group of small seeds (10 to 12 to the grain) are English, Dutch, Russian, and ordinary Calcutta varieties. An important practical point noticed by Holmes is that much of the drug of commerce is adulterated with weed seeds, which are nearly always smaller than the linseeds, and can therefore be separated by the sieve. When linseed meal is to be made for medicinal use, this separation should always be insisted upon, as many of the weed seeds are from Cruciferæ, and are irritating. For detailed information as to varieties of linseed, weed seeds, etc., the reader is referred to Holmes's paper. (*P. J.*, July, 1881; also *N. R.*, 1881.)

The ground seeds are found in commerce under the name of *flaxseed meal*. This is of a brownish gray color, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by practical chemists.

Crushed flaxseed is "a coarse, brownish-yellow powder, with readily visible fragments of the brown seed-coats. Bland, not pungent or rancid, odor when mixed with warm *water*. Yields not less than 30 per cent. of oil when exhausted by *carbon disulphide;* the oil thus obtained responds to the tests described under 'Oleum Lini'; the residual powder exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent." *Br.*

Much of the linseed meal of commerce is simply cake meal, which was, indeed, official in the former Br. Ph., but such meal is unfit for medicinal use, not only because it contains very little oil, but also because the oil which is in it has, through rupture of the cells and partial expression, been so exposed to the air as to become rancid. The residue after expression of the oil is used as a cattle-food. Linseed meal is sometimes adulterated with corn meal, or other meals containing starch, whose presence is at once revealed by the iodine test. It has been found in the market adulterated with petroleum or other mineral oil, doubtless made by powerfully pressing the pure linseed meal and substituting for the linseed oil the less expensive product, petroleum. (*A. J. P.*, 1902, 31.)

The absolute value of a sample of crushed linseed can be determined by analysis. It should contain from 25 to 35 per cent. of oil, not more than 8 or 8.5 per cent. of husk, and less than 8 per cent. of ash. The following *test* is said to be sufficient for practical purposes: "Put half an ounce of the meal into a glass vessel, pour six ounces of boiling water over it, stir well, and allow it to stand for twelve hours. If first-class, it should absorb all the water, and show a thin scum of white glutinous liquid on the top, which will adhere closely to a glass rod or a wooden pencil dipped into it. If the meal does not absorb nearly all the water, it is of inferior quality. The amount of inferiority must be judged by the amount of water not absorbed, and by the character of the fluid on the top of the solution. If it is thin and nonglutinous, the meal is of inferior quality."

Linseed contains from 30 to 40 per cent. of a characteristic fixed oil (see *Oleum Lini*) besides wax, resin, tannin, gum and protein. For some years there has been a discussion as to the presence of starch. Certain tissues of the seed coat beneath the mucilaginous epidermis may give a starch reaction and it is stated that even the cells may contain starch (*Proc. A. Ph. A.*, 1907, lv, p. 326). The present indications are that starch grains are not usually present in the ripe seed although they may occur in appreciable quantities in the immature seeds (*Ph. Ztg.*, li, p. 658). The investing coat of the seed abounds in a peculiar gummy matter or mucilage amounting to about 6 per cent. of the seeds. This is readily soluble in hot water forming a thick viscid mucilage which deposits white flakes upon the addition of alcohol and affords a copious dense precipitate with lead subacetate. Albuminous matter is present to the extent of about 20 per cent. and sugars to the extent of about 18 per cent.

The ash of flaxseed amounts to from 2 to 6 per cent. of the weight of the seed.

The gum of linseed contains in the dry state more than 10 per cent. of mineral substances; when freed from these and dried at 110° C., it has, like althæa mucilage, the formula $C_{12}H_{20}O_{10}$. The seeds by exhaustion with cold or warm water afford about 15 per cent. of this mucilage. By boiling with nitric acid, it yields crystals of mucic acid; by diluted mineral acids, it is broken up into dextrogyrate gum, sugar, and cellulose. (Kirchner and Tollens, *Ann. Ch.*

Ph., clxxv, 215.) For further information on the histology and pharmacognosy of the flaxseed, see Winton and Moeller, "The Microscopy of Vegetable Foods;" Kate B. Winton, *Bot. Gaz.*, lviii, p. 2445; Collin, *J. P. C.*, 1909, xxix, p. 369.

Jorissen and Hairs (*Drogues Simples*, t. ii, 685) obtained from the young plant a glucoside, to which they gave the name of *linamarin*, which crystallizes in colorless needles, melting at 134° C., without odor, but possesses a fresh and bitter taste. It differs from amygdalin in not being decomposed by emulsin, but diluted acids decompose it into sugar, hydrocyanic acid, and a third product which is volatile and possesses certain of the characters of the acetones. No benzaldehyde is formed.

Uses.—Because of the mucilage and oil it contains, flaxseed is both demulcent and emollient. The meal mixed with hot water forms an excellent emollient poultice which is of much value in the treatment of local inflammations such as *furunculosis*. Its peculiar usefulness is due partially to the oil which softens the skin and partially to the fact that the flaxseed poultice retains heat much better than most substitutes. There is a popular notion that the mucilaginous substances can be absorbed and exercise an internal demulcent action, and an infusion made by treating the whole seeds with boiling water is widely employed in catarrhs of the respiratory or urinary tracts. But as the gums, like other carbohydrates, are affected by digestive juices, much benefit is not to be expected from such a use of the drug. The whole seed is occasionally given in tablespoonful doses as a laxative.

LIQUOR ACIDI ARSENOSI. U. S. (Br.)

SOLUTION OF ARSENOUS ACID Liq. Acid. Arsen. [Hydrochloric Solution of Arsenic, Solution of Arsenic Chloride]

"Solution of Arsenous Acid contains, in each 100 cc., the equivalent of not less than 0.975 Gm. and not more than 1.025 Gm. of As_2O_3." *U. S.*

Liquor Arsenici Hydrochloricus, *Br.;* Liquor Arsenici Chloridi, *U. S. P.* 1870; Liqueur de Boudin, Liqueur arsénicale hydrochlorique, *Fr.;* Chlorarsenik-Lösung, *G.*

"Arsenic Trioxide, 10 Gm.; Diluted Hydrochloric Acid, 50 cc.; Distilled Water, a sufficient quantity to make 1000 cc. Mix the diluted hydrochloric acid with 250 cc. of distilled water in a flask, add the arsenic trioxide, and boil the liquid until the arsenic trioxide is completely dissolved. Allow the solution to cool, transfer it to a 1000 cc. graduated flask or cylinder, rinse the vessel in which the solution was boiled, with several portions of distilled water, and add the rinsings and enough distilled water to make the product measure 1000 cc. Filter if necessary." *U. S.*

"Arsenious Anhydride, in powder, 10 *grammes;* Hydrochloric Acid, 12 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres*. Dissolve the Arsenious Anhydride and the Hydrochloric Acid in five hundred *millilitres* of Distilled Water by the aid of heat; cool; add sufficient Distilled Water to produce the required volume." *Br.*

This solution is stronger than the *Liquor Arsenici Chloridi* of the U. S. P., 1870. The name has also been changed, as the former title was a misnomer. The hydrochloric acid does not enter into combination with the arsenic trioxide; it merely aids in its solution. True arsenic chloride, As_2Cl_6, cannot exist in aqueous solution but is immediately hydrolized into arsenous and hydrochloric acids. The British title is, in our opinion, to be preferred, because the U. S. name does not indicate the presence of the hydrochloric acid.

Description and Physical Properties.—"A clear, colorless liquid without odor. Solution of Arsenous Acid is acid to litmus paper. Hydrogen sulphide T.S. added to Solution of Arsenous Acid produces a lemon-yellow precipitate of arsenic trisulphide, which is completely soluble in ammonium carbonate T.S.

"**Assay.**—Measure exactly 20 cc. of Solution of Arsenous Acid and dilute with about 50 cc. of distilled water, dissolve enough sodium bicarbonate in this solution to make it distinctly alkaline (usually about 2 Gm.), and titrate with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3." *U. S.*

According to the British Pharmacopœia, it is "a colorless liquid; acid to *litmus*. 25 millilitres diluted with *water* discharge the color of 50.4 millilitres of *N/10 solution of iodine*, the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. This Solution contains 1 gramme of Arsenious Anhydride in 100 millilitres; 110 minims contain 1 grain." *Br.*

Uses.—The medicinal properties of this solution are the same as those of Fowler's solution, with which it corresponds in strength.

Dose, from two to eight minims (0.12–0.5 cc.).

Off. Prep.—Elixir Chloridorum, *N. F.*

LIQUOR ACIDI CHROMICI. Br.

SOLUTION OF CHROMIC ACID

Soluté d'Acide Chromique, *Fr. Cod.;* Chromsaurelösung, *G.*

"Chromic Anhydride, 25 *grammes;* Distilled Water sufficient to produce 100 *millilitres*. Dissolve." *Br.*

This was officially described in the British Pharm., 1898, as "an orange-red, inodorous, caustic, strongly acid liquid. Specific gravity, 1.185. It should respond to the tests described under 'Acidum Chromicum.'"

It is simply a definite solution of chromic anhydride (25 per cent.), which unites with the water to form chromic acid, H_2CrO_4, and will probably be found convenient as a caustic application. (See *Chromii Trioxidum.*) It is not used internally.

LIQUOR AMMONII ACETATIS.
U. S., Br.

SOLUTION OF AMMONIUM ACETATE Liq. Ammon. Acet. [Spirit of Mindererus]

“Solution of Ammonium Acetate contains, in each 100 cc., not less than 6.5 Gm. and not more than 7.5 Gm. of $NH_4C_2H_3O_2$, with small amounts of acetic and carbonic acids. *Caution—Only a recently prepared Solution of Ammonium Acetate should be dispensed.*” *U. S.*

Spiritus Mindereri; Liquor Ammoniæ Acetatis; Acétate d'Ammoniaque liquide, Esprit de Mindérérus, *Fr.;* Liquor Ammonii Acetici, *P. G.;* Ammoniumacetatlösung, Essigsaure Ammoniumlösung, *G.*

“Ammonium Carbonate, in hard, translucent pieces, 5 Gm.; Diluted Acetic Acid, 100 cc. Dissolve the ammonium carbonate in the diluted acetic acid without strong agitation.

“Solution of Ammonium Acetate may also be prepared as follows: *Solution No. 1.* Ammonium Carbonate, in hard, translucent pieces, 50 Gm.; Distilled Water, a sufficient quantity to make 500 cc. *Solution No. 2.* Acetic Acid, 160 cc.; Distilled Water, a sufficient quantity to make 500 cc. Cautiously mix the two solutions in equal volumes in a capacious vessel, in quantities sufficient to produce the amount of Solution of Ammonium Acetate needed.” *U. S.*

“Acetic Acid, 162.5 *millilitres;* Ammonium Carbonate, 50.0 *grammes,* or a sufficient quantity; Distilled Water sufficient to produce 1000.0 *millilitres.* Mix the Acetic Acid with five hundred *millilitres* of the Distilled Water; neutralise with Ammonium Carbonate; add sufficient Distilled Water to produce the required volume.” *Br.*

This preparation is an aqueous solution of ammonium acetate. The process by which it is formed involves the decomposition of ammonium carbonate by diluted acetic acid. In order to prepare this solution of official quality and the proper reaction the ammonium carbonate must be in translucent pieces as directed, and must not be effloresced.

Description and Physical Properties.—“A clear, colorless liquid, free from empyreumatic odor. It has a mildly saline, acidulous taste, and an acid reaction. Solution of Ammonium Acetate responds to the reactions for ammonium, and for acetates. Not more than 0.003 Gm. of ash remains on evaporating 20 cc. of the Solution and igniting the residue.

“**Assay.**—Transfer 25 cc. of Solution of Ammonium Acetate to a distilling flask, dilute with 100 cc. of distilled water, add 25 cc. of 10 per cent. sodium hydroxide solution, and distil the liquid until all of the ammonia has been driven over (about 100 cc. of distillate), receiving the distillate under the surface of 50 cc. of normal sulphuric acid contained in a flask. Titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.07707 Gm. of $NH_4C_2H_3O_2$.” *U. S.*

“Specific gravity 1.016. Mixed with an equal volume of a saturated aqueous solution of *hydrogen sulphide* not more than the slightest darkening in color results (limit of heavy metals). Solution of Ammonium Acetate should be preserved in a vessel free from lead.” *Br.*

Uses.—Solution of ammonium acetate is used as a saline diaphoretic and diuretic, especially in febrile conditions.

Dose, from half a fluidounce to a fluidounce and a half (15–45 cc.) every three or four hours, mixed with water and sweetened with sugar.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, *U. S.*

LIQUOR AMMONII CITRATIS. Br.

SOLUTION OF AMMONIUM CITRATE

Citrate d'Ammoniaque liquide, *Fr.;* Ammoniumcitratlösung, Citronensaure Ammoniak-Flüssigkeit, *G.*

“Citric Acid, 125.0 *grammes;* Ammonium Carbonate, 87.5 *grammes,* or a sufficient quantity; Distilled Water sufficient to produce 1000.0 *millilitres.* Dissolve the Citric Acid in five times its weight of Distilled Water; neutralise with Ammonium Carbonate; add sufficient Distilled Water to produce the required volume. Specific gravity, 1.057. Mixed with an equal volume of a saturated aqueous solution of *hydrogen sulphide* not more than the slightest darkening in color results (limit of heavy metals). Solution of Ammonium Citrate should be preserved in a vessel free from lead.” *Br.*

This solution is also official in the N. F. (See Part III.)

This solution may be used for the same purposes as *Solution of Ammonium Acetate.*

Dose, from two to six fluidrachms (7.5–22.5 cc.).

LIQUOR ARSENI ET HYDRARGYRI IODIDI.
U. S. (Br.)

SOLUTION OF ARSENOUS AND MERCURIC IODIDES Liq. Arsen. et Hydrarg. Iod. [Donovan's Solution]

“Solution of Arsenous and Mercuric Iodide is an aqueous solution containing, in each 100 cc., not less than 0.95 Gm. and not more than 1.05 Gm. of AsI_3, and not less than 0.95 Gm. and not more than 1.05 Gm. of HgI_2.” *U. S.*

Liquor Arsenii et Hydrargyri Iodidi, *Br.;* Solution of Arsenious and Mercuric Iodides; Liquor Arsenici et Hydrargyri Iodidi, *Br.* 1867, *U. S.* 1870; Solution of Hydriodate of Arsenic and Mercury; Solutio Donovani; Soluté d'Iodo-arsénite de Mercure, Liqueur de Donovan, *Fr.;* Jodquecksilber Arseniklösung, Donovansche Tropfen, *G.*

“Arsenous Iodide, 10 Gm.; Red Mercuric Iodide, 10 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Triturate the arsenous iodide and red mercuric iodide in a mortar, add 150 cc. of distilled water, and continue the trituration until solution is effected. Filter the solution, and pass sufficient distilled water through the filter to make the product measure 1000 cc. Mix thoroughly. It must not be dispensed if darker than pale yellow.” *U. S.*

“Arsenious Iodide, 10 *grammes;* Red Mercuric Iodide, 10 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Triturate the Arsenious Iodide and Red Mercuric Iodide with two hundred and fifty *millilitres* of the Distilled Water until dissolved; filter; pass through the filter sufficient Distilled Water to produce the required volume. This Solution contains the equivalent of 1 gramme of Arsenious Iodide and 1 gramme of Red Mercuric Iodide in 100 millilitres; 110 minims contain the equivalent of 1 grain of each salt." *Br.*

This solution was introduced to the notice of the medical profession in 1839 by Donovan, of Dublin, as a therapeutic agent combining the medicinal virtues of its three ingredients, and was adopted as an official preparation in the U. S. and Dublin Pharmacopœias of 1850. The formula is the simplified one of Procter, which consists essentially in dissolving equal weights of arsenic triiodide and mercuric iodide (red iodide) in a measured quantity of distilled water.

Description and Physical Properties.—"A clear, colorless or pale yellowish liquid. Lead acetate T.S. produces in Solution of Arsenous and Mercuric Iodide, diluted with 10 volumes of distilled water, a bright yellow precipitate. Add 5 drops of Solution of Arsenous and Mercuric Iodide to a mixture of about 0.5 Gm. of zinc and 5 cc. of diluted hydrochloric acid in a test tube, and cover the mouth of the test tube with mercuric bromide test paper: a yellow stain appears upon the inner surface of the test paper within one minute. Solution of Arsenous and Mercuric Iodide responds to the tests for mercury, page 443.

"**Assay for Arsenous Iodide.**—Measure accurately 25 cc. of Solution of Arsenous and Mercuric Iodide into a flask, dilute with 25 cc. of distilled water, then dissolve 2 Gm. of sodium bicarbonate in this solution, and titrate with tenth-normal iodine, using starch T.S. as indicator. Each cc. of tenth-normal iodine corresponds to 0.02279 Gm. of AsI_3.

"**Assay for Mercuric Iodide.**—Measure accurately 25 cc. of Solution of Arsenous and Mercuric Iodide into a flask, add 5 cc. of potassium hydroxide T.S. and 5 cc. of formaldehyde T.S., and warm the mixture on a water bath until the mercuric salt has been completely reduced to metallic mercury. Carefully decant the clear, supernatant liquid from the residue of metallic mercury, and wash the mercury carefully by decantation with two successive portions of 25 cc. each of distilled water. Dissolve the residue of metallic mercury in 5 cc. of nitric acid by the application of gentle heat, dilute the solution with 50 cc. of distilled water, add 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.02272 Gm. of HgI_2.

"Preserve in well-filled, amber-colored bottles." *U. S.*

Uses.—This preparation has been found decidedly useful as an alterative in various chronic diseases of the skin, such as in the later stages of *syphilis,* especially with "night pains;" in certain cases of *lymphadenitis* and in some forms of chronic joint disease.

Dose, from one to five minims (0.06–0.3 cc.), three times a day, given preferably in distilled water.

LIQUOR ATROPINÆ SULPHATIS. Br.

SOLUTION OF ATROPINE SULPHATE

Soluté de Sulfate d'Atropine, *Fr.;* Schwefelsaure Atropinlösung, *G.*

"Atropine Sulphate, 1 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Dissolve. This Solution should be freshly prepared. It contains 1 gramme of Atropine Sulphate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This solution contains 1 per cent. of atropine sulphate. Camphor water was substituted for distilled water on account of its antiseptic properties at the 1885 revision. Salicylic acid and distilled water were used (1898) with the same object in view, but the British Pharm., 1914, discarded preservatives. The solution readily develops a mould and loses strength. Therefore it should be freshly prepared as ordered.

Dose, one-half to one minim (0.03–0.06 cc.).

LIQUOR BISMUTHI ET AMMONII CITRATIS. Br.

SOLUTION OF BISMUTH AND AMMONIUM CITRATE

Liquor Bismuthi; Solution of Bismuth, Liquid Bismuth; Soluté de Citrate de Bismuth ammoniacal, *Fr.;* Citronensaure Wismuth-Ammoniak-Lösung, Wismuth-Ammoniakcitratlösung, *G.*

"Bismuth Oxynitrate, 70 *grammes;* Citric Acid, 52 *grammes;* Solution of Ammonia, Distilled Water, of each, *a sufficient quantity.* Powder the Citric Acid and mix it in a mortar with the Bismuth Oxynitrate and twenty *millilitres of Distilled Water.* Allow the mixture to stand, with occasional stirring, for half an hour, or until a small portion is completely soluble in Solution of Ammonia. Transfer to a beaker, using four hundred *millilitres* of Distilled Water to rinse the mortar. Allow the precipitate to settle, remove the clear liquid by decantation, and wash the precipitate with three successive quantities, each of four hundred *millilitres,* of Distilled Water. Add to the washed precipitate, while moist, just sufficient Solution of Ammonia to dissolve it, and then add sufficient Distilled Water to produce one thousand *millilitres* of the Solution." *Br.*

Various formulas for a similar solution have been suggested (see *U. S. D.,* 17th ed., 794, and 19th ed., 706), but that official is probably as good as any.

The British Pharmacopœia describes this preparation as "a colorless liquid, freely miscible with *water;* taste somewhat metallic; slightly alkaline to *litmus.* Evolves ammonia when heated with *solution of sodium hydroxide.* 10 millilitres, evaporated to dryness and the residue ignited, yield not less than 0.5 gramme of bismuth oxide." *Br.*

Uses.—See under *Bismuthi et Ammonii Citratis.*

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

LIQUOR CALCII HYDROXIDI. U. S. (Br.)

SOLUTION OF CALCIUM HYDROXIDE Liq. Calc. Hydrox. [Liquor Calcis, U. S. P. IX, Lime Water]

"Solution of Calcium Hydroxide is an aqueous solution containing, in each 100 cc., not less than 0.14 Gm. of $Ca(OH)_2$ at 25° C. The strength in calcium hydroxide varies with the temperature at which the solution is stored, being about 0.17 Gm. per 100 cc. at 15° C. and diminishing as the temperature rises." *U. S.*

Liquor Calcis, *Br.;* Aqua Calcariæ Ustæ, Calcaria Soluta, Solutum Calcis; Solution of Calcium Hydrate, Solution of Lime; Eau (Soluté) de Chaux, *Fr.;* Aqua Calcis, *Fr. Cod.;* Aqua Calcariæ, *P. G.;* Kalkwasser, *G.;* Acqua di calce, *It.;* Agua de cal, *Sp.*

"Lime, 25 Gm.; Water, a sufficient quantity. Slake the Lime by the addition of about 50 cc. of warm water. Transfer the mixture to a bottle having a capacity of about 4000 cc., and add 950 cc. of water. Agitate the mixture occasionally during half an hour, allow it to settle, and then decant and reject the clear liquid. To the residue add sufficient water to make about 4000 cc., agitate thoroughly, stopper the bottle and set it aside in a cool place. Decant and dispense the clear liquid. The undissolved portion should not be used for making additional quantities of Solution of Calcium Hydroxide unless the solution so prepared, is found to be of full strength when assayed." *U. S.*

"Calcium Hydroxide, 50 *grammes;* Distilled Water, *a sufficient quantity.* Wash the Calcium Hydroxide with Distilled Water until free from chlorides; then shake it with five thousand *millilitres* of Distilled Water in a stoppered green glass bottle for two or three minutes; set aside until clear. The clear Solution may be drawn off with a siphon as required for use, and should then be transferred to a green glass bottle." *Br.*

A solution of calcium hydroxide, $Ca(OH)_2$, in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved hydroxide, which causes it always to be saturated whatever may be the temperature. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than when cold. Hence the propriety of employing cold water in the process. For Green's automatic device for dispensing lime water in excellent condition, see *Proc. A. Ph. A.,* 1893, 474; see also 1904, 66.

The practice of using the undissolved lime indefinitely by refilling the bottle with water, is reprehensible, as notwithstanding the excess, its tendency to become carbonated and insoluble is great, and lime water is often dispensed deficient in strength; it is much safer to use the lime but once or twice than to run the risk of dispensing a liquid of insufficient strength.

The small tubes or vials of purified calcium hydroxide which are now available for the quick and convenient preparation of lime water are satisfactory only when properly preserved and when used exactly according to directions. Lime water cannot be instantly prepared extemporaneously as is sometimes attempted. The preparation when made too quickly is usually deficient in strength. Exposed to the air it attracts carbon dioxide, and becomes covered with a pellicle of insoluble calcium carbonate, which, subsiding after a time, is replaced by another, and so on successively until the whole of the lime is precipitated. Hence the necessity of keeping lime water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime.

Description and Physical Properties.—"A clear, colorless, odorless liquid with an alkaline taste. Specific gravity: about 1.00 at 25° C. Solution of Calcium Hydroxide is strongly alkaline to litmus paper. It absorbs carbon dioxide from the air, a film of calcium carbonate forming on the surface of the liquid. On being heated it becomes turbid, due to the separation of calcium hydroxide which redissolves when the liquid is cooled. The alkaline reaction of the Solution entirely disappears after it has been saturated with carbon dioxide and subsequently boiled (*alkalies and their carbonates*).

"**Assay.**—Titrate exactly 50 cc. of Solution of Calcium Hydroxide, at 25° C., with tenth-normal sulphuric acid, using phenolphthalein T.S. as indicator. Each cc. of tenth-normal sulphuric acid corresponds to not less than 0.003705 Gm. of $Ca(OH)_2$.

"Preserve in well-filled, tightly-stoppered bottles." *U. S.*

"Twenty-four millilitres require for neutralisation 10 millilitres of *N/10 solution of sulphuric acid.* Yields no characteristic *reactions* for lead or chlorides. This Solution contains the equivalent of rather more than 0.1 gramme of Lime, CaO, in 100 millilitres; 110 minims contain the equivalent of 1/10 grain." *Br.*

Uses.—Lime water is mildly antacid and astringent, often useful in *dyspepsia* with acidity of stomach or *diarrhea.* Mixed with from one to three measures of milk, which completely covers its offensive taste, it is of service in *nausea* and *vomiting* dependent on irritability of stomach. It is often added to milk to prevent the formation of hard curds, and thus increase its digestibility. In severe repeated vomiting with loss of digestive power a diet exclusively of lime water and milk (one to six) is often very effectual. It was formerly employed as a local remedy in *pseudo-membranous croup* by directing lime water spray, produced by the atomizer, so that it shall be inhaled by the patient. When employed to allay *nausea,* it is usually given in the dose of a tablespoonful mixed with the same quantity of milk, and repeated at intervals of half an hour, an hour, or two hours.

Dose, one to four fluidounces (30–120 cc.).

Off. Prep.—Linimentum Calcis, *U. S., Br.*

LIQUOR CALCIS CHLORINATÆ. Br.

SOLUTION OF CHLORINATED LIME

Soluté d'Hypochlorite de Chaux, *Fr. Cod.;* Chlorure de Chaux liquide, *Fr.;* Chlorkalklösung, Chlorkalk-Flüssigkeit, *G.*

"Chlorinated Lime, 100 *grammes;* Distilled Water, 1000 *millilitres.* Mix; transfer the mixture to a stoppered bottle; set aside for three hours, shaking occasionally; filter through calico. Preserve the filtrate in a stoppered bottle in a cool dark place." *Br.*

For the properties and uses of this preparation, see *Calx Chlorinata.* The British Pharmacopœia gives the following tests: "If 2 *millilitres* are added to a solution of 1 gramme of *potassium iodide* in 25 *millilitres* of *water,* acidified with 2 *millilitres* of *hydrochloric acid,* a brownish-red solution is obtained which requires for decolorisation not less than 11.7 *millilitres* of *N/10 solution of sodium thiosulphate* (presence of not less than 2 per cent. of available chlorine). When freshly prepared, this Solution yields about 3 per cent. of available chlorine." *Br.*

This solution loses strength rapidly and should therefore be prepared as needed. It is one of the best antidotes against poisoning by hydrogen sulphide, ammonium sulphydrate, potassium sulphide, and hydrocyanic acid. For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections.

Dose, for internal use, from ten to thirty minims (0.6–1.9 cc.).

LIQUOR CALCIS SACCHARATUS. Br.

SACCHARATED SOLUTION OF LIME

Syrupus Calcis (*U. S. VIII*); Syrup of Lime; Syrup of Calcium Hydroxide; Syrupus Calcariæ; Syrup of Calcium Hydroxide; Sirop de Chaux, *Fr.;* Kalksyrup, *G.*

"Calcium Hydroxide, 50 *grammes;* Refined Sugar, in powder, 100 *grammes;* Distilled Water, 1000 *millilitres.* Mix the Calcium Hydroxide with a solution of the Refined Sugar in the Distilled Water. Set aside in a stoppered green glass bottle for a few hours, shaking occasionally; separate the clear Solution by means of a siphon, avoiding unnecessary exposure to air. Specific gravity, 1.055. Twenty millilitres require for neutralisation 13.2 millilitres of *N/1 solution of sulphuric acid.* Yields no characteristic *reactions for lead.* This Solution contains the equivalent of nearly 2 grammes of Lime, CaO, in 100 millilitres; 110 minims contain nearly 2 grains." *Br.*

Sugar forms with lime certain definite compounds which may be looked upon as sucrates. According to M. S. Benedikt (*J. P. C.,* 4e sér., xix, 96), there are at least four of these combinations. Some, if not all, of them are much more soluble than the lime itself, so that in this way a much stronger solution of lime can be obtained than by the instrumentality of water alone. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It is sometimes employed as a milk thickener and when added to cream increases the viscosity so it may be easily "whipped."

Uses.—Syrup of lime is an active antacid and astringent, which may be used as a substitute for lime water in all cases in which that preparation is suitable. Twenty minims of it (1.3 cc.) are equal to a fluidounce of lime water.

Dose, fifteen to sixty minims (0.9–3.75 cc.).

LIQUOR CRESOLIS COMPOSITUS. U. S. (Br.)

COMPOUND SOLUTION OF CRESOL Liq. Cresol. Co.

Liquor Cresol Saponatus, *Br.;* Solution of Cresol with Soap; Soluté de Crésol composé, *Fr.;* Liquor Cresoli saponatus, *P. G.;* Kresolseifenlösung, *G.*

"Cresol, 500 cc.; Linseed Oil, 350 cc.; Dekanormal Solution of Potassium Hydroxide, 22 cc.; Dekanormal Solution of Sodium Hydroxide, 88 cc.; Water, a sufficient quantity to make 1000 cc. Mix the cresol and linseed oil, add the dekanormal solutions (see pages 501 and 504) and mix well. Heat the mixture to about 70° C. until a portion gives a clear solution when mixed with nine volumes of cold water, cool, and add sufficient water to make the product measure 1000 cc.

"NOTE.—The 22 cc. of dekanormal solution of potassium hydroxide directed above may be replaced by 14.52 Gm. of 85 per cent. potassium hydroxide and the 88 cc. of dekanormal solution of sodium hydroxide may be replaced by 39.11 Gm. of 90 per cent. sodium hydroxide, dissolving the hydroxides in 50 cc. of water. If upon assay the potassium and the sodium hydroxides are found to be of any other strength, a proportionately larger or smaller quantity should be taken." *U. S.*

For description of the dekanormal solutions, see Part III.

"Cresol, 500 *grammes;* Castor Oil, 350 *grammes;* Potassium Hydroxide, 80 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix the Cresol with the Castor Oil and heat to 80° C. Dissolve the Potassium Hydroxide in seventy *millilitres* of the Distilled Water. Mix the two solutions and heat the mixture until one volume of it forms a clear liquid with ten volumes of Distilled Water. Cool, and add sufficient Distilled Water to produce the required volume." *Br.*

The formula of the U. S. X differs from that of the previous edition in that it contains both potassium and sodium hydroxide.

A number of suggested improvements have appeared in the literature for making this solution. F. M. Jordan (*Ph. Era,* 1919, lii, p. 175) uses the official ingredients but modifies the directions somewhat. S. L. Hilton (*J. A. Ph. A.*, 1919, viii, p. 759) employs oleic acid and sodium hydroxide in making the soap and claims that a fine preparation can be made in fifteen minutes, costing but 60 cents a litre.

Assay.—" Mix in a 500 cc. distilling flask 50 cc. of Compound Solution of Cresol, accurately measured at 25° C., with 150 cc. of purified kerosene. Add 3 Gm. of sodium bicarbonate and distil through an upright condenser, at the rate of not more than 2 drops per second, until the distillate comes over strongly yellow, receiving the distillate in a 250 cc. to 300 cc. separatory funnel. Run off the lower aqueous layer, shake the kerosene layer with 10 cc. of sulphuric acid (49 to 51 per cent.), allow to stand for two hours, then draw off the acid layer completely, and discard it. Add to the kerosene layer 40 cc. of an aqueous sodium hydroxide solution (15 per cent.), accurately measured at 25° C., shake well for five minutes, then allow to stand until complete separation has taken place, and draw off the sodium hydroxide layer into a graduated cylinder. Shake the kerosene layer again with a fresh portion of 20 cc. of the 15 per cent. sodium hydroxide solution, accurately measured at 25° C., allow the two layers to separate completely, and draw off the sodium hydroxide layer into the graduated cylinder. Adjust the sodium hydroxide solution in the graduated cylinder to a temperature of 25° C. and note the volume. The difference between the volume noted and the total volume of sodium hydroxide solution used represents the volume of cresol present in 50 cc. of Compound Solution of Cresol. This difference is not less than 23 cc. and not more than 26 cc. Transfer the sodium hydroxide solution of the cresol obtained in the assay to a separatory funnel and add sufficient hydrochloric acid to render the solution distinctly acid. Allow the precipitated cresol to separate completely and draw off the lower aqueous layer. Wash the cresol with several successive portions of 20 cc. each of a saturated aqueous solution of sodium chloride until the washings are neutral or only slightly acid. Then add to the washed cresol about 5 Gm. of freshly ignited potassium carbonate, shake gently at frequent intervals during three hours, and allow to stand overnight. The cresol decanted from the potassium carbonate meets the distillation requirements for *Cresol,* when determined by Method II." *U. S.*

Uses.—This solution is intended as a substitute for the many commercial preparations of cresol on the market. Although it forms a clear solution with distilled water, with tap water it becomes cloudy, owing to precipitation of lime soaps. This change, however, does not appear to interfere with its therapeutic properties. It is a powerful germicidal mixture, at least twice as strong as phenol as a destroyer of micro-organisms. It is also less caustic than phenol, but the statement that it is much less poisonous has been shown to be untrue. A large number of deaths are reported annually from solutions of this type. It is especially useful for sterilizing instruments and the skin, its soapy nature making it peculiarly valuable for the latter purpose. It may be diluted with from 30 to 90 times its bulk of water (3 per cent. to 1 per cent. solution). It has been used to a small extent internally as an antiseptic in *fermentative gastritis.*

Numerous methods have been suggested for assaying this preparation. None of them are simple and satisfactory enough for adoption as an official method. See the following references for methods of assay. Verda (*Schweiz. Apoth. Ztg.,* 1920, lviii, p. 238); Van Os (*Ph. Wb.,* 1920, lvii, p. 692); Jordan (*C. D.,* 1921, xciv, p. 843); Bohrisch (*Pharm. Zentralh.,* 1921, lxii, 297).

Dose, one to two minims (0.06–0.12 cc.).

LIQUOR EPINEPHRINÆ HYDROCHLORIDI. U. S. (Br.)

SOLUTION OF EPINEPHRINE HYDROCHLORIDE
Liq. Epineph. Hydrochlor.

" Solution of Epinephrine Chloride is a solution of epinephrine in water and hydrochloric acid, containing in each 100 cc. not less than 0.095 Gm. and not more than 0.105 Gm. of $C_9H_{13}O_3N$. Solution of Epinephrine Hydrochloride, diluted with physiological solution of sodium chloride in the proportion of one part of the Solution of Epinephrine Hydrochloride to 99 parts of the salt solution, and injected intravenously into dogs by the method described below, produces a rise in the systolic blood-pressure of the dog corresponding to that produced by an equal amount of the standard solution of epinephrine hydrochloride prepared as directed below." *U. S.*

Liquor Adrenalini Hydrochloricus, *Br.;* Hydrochloric Solution of Adrenalin; Solution of Adrenalin Hydrochloride.

" Adrenalin, 1 *gramme;* Chloroform, 5 *millilitres;* Sodium Chloride, 9 *grammes;* Diluted Hydrochloric Acid, 3 *millilitres;* Distilled Water, recently boiled and cooled, sufficient to produce 1000 *millilitres.* Dissolve the Chloroform and the Sodium Chloride in nine hundred *millilitres* of the Distilled Water, add the Diluted Hydrochloric Acid, dissolve the Adrenalin in the mixture, and add sufficient Distilled Water to produce the required volume. Preserve the Solution in amber glass bottles." *Br.*

Epinephrine was originally placed upon the market in the form of a proprietary solution containing one part of the hydrochloride in 1000 and is still chiefly used in this form. The Br.

gives a formula for the preparation of this solution, but the U. S. omits any formula because the revisers considered that the preparation of a satisfactory solution of this salt required such technical skill that it was not practicable for retail pharmacists. This solution contains free acid and sodium chloride with a little chloroform to act as a preservative. Care should be used to avoid the presence of iron in compounding prescriptions as it is incompatible. Steel spatulas must not be brought in contact with adrenalin solutions. In fact, it is desirable to prescribe the solution without admixture, and in original containers.

The reason for this is found in the fact that not only is epinephrine very unstable in solution except under certain carefully regulated conditions, but that if improperly prepared it will prove either irritating or inert. The stability is best attained in the presence of small amounts of acid. If, however, the acid is present to the extent of more than a few hundredths per cent. the solution becomes very irritating especially when used in conditions where inflammation is present. If the acidity is too low, the reaction is likely to become alkaline from the natural alkalinity of the glass and the preparation becomes discolored and inert. In the case of ampules, which must be sterilized it is necessary to use special glass, free from alkalinity even when treated with water at high temperatures. The solutions on the market are frequently protected from oxidation also by replacing the air in the container with carbon dioxide.

Description and Physical Properties.—"A nearly colorless, slightly acid liquid, gradually turning dark on exposure to air and light. When the solution has become brown in color or contains a precipitate, it must be rejected.

"The addition of 1 drop of ferric chloride T.S. to 10 cc. of the solution produces an emerald-green color which soon turns to a cherry-red and finally to brown. Other oxidizing agents produce red to pink or violet colors which change on standing. Fixed alkali hydroxides darken it, but do not precipitate the epinephrine.

"Preserve in small, well-filled, amber-colored bottles." *U. S.*

Assay.—It has been suggested to standardize epinephrine solution by the change of color which is caused by oxidizing agents; indeed this principle was official for suprarenal glands in the U. S. IX, which employed manganese dioxide as the oxidizant. A process similar in principle but using potassium iodate has been proposed by White (*P. J.*, 1917, xcviii, 159). None of these methods, however, have proven entirely satisfactory and the present U. S. P. makes use of a biological assay process which is as follows:

"Prepare a standard solution of epinephrine hydrochloride from the standard epinephrine by dissolving 0.050 Gm. of epinephrine in 5 cc. of tenth-normal hydrochloric acid, and dilute this to 50 cc. by the addition of distilled water, thus making a 1 in 1000 solution. For the assay, add 1 cc. of this 1 in 1000 solution to 99 cc. of physiological solution of sodium chloride. This dilute solution (1 in 100,000) must be freshly prepared when needed. On account of the possibility of deterioration, the 1 in 1000 solution must have been recently prepared. It will keep for a short time if preserved in amber-colored bottles in a refrigerator, but it must be discarded if any signs of deterioration, such as discoloration, are observed. Add 1 cc. of the Solution of Epinephrine Hydrochloride to be tested to 99 cc. of physiological solution of sodium chloride, and thoroughly mix. For the purpose of the assay, the dog to be used should be of medium size and be anesthetized with a suitable anesthetic. It is prepared for blood-pressure estimations by inserting a cannula into the carotid artery and connecting the same with a mercury manometer. The trachea may also be exposed and a cannula inserted so that the animal may receive artificial respiration during the course of the experiment if necessary. The injections are made into the exposed femoral vein. Before the test is made, in case any muscular movement such as twitching is present, the dog should receive by intravenous injection a sufficient dose of curare (page 475), but if the animal is deeply anesthetized, this is not necessary. The dog should also receive a sufficient dose of atropine sulphate (from 0.001 Gm. to 0.002 Gm.) to paralyze the vagi, this paralysis being proved by electrical stimulation. The blood-pressure tracing is recorded on a kymograph. Injections must be made at regular intervals of approximately five minutes. Determine the amount of standard solution necessary to cause a rise in blood-pressure of from 30 to 60 mm. by injecting intravenously varying doses of the solution and after a satisfactory dose has been ascertained, the uniformity of reaction should be tested by the injection of two or more doses of equal size. If these injections produce approximately equal increases in blood-pressure, alternate injections of the solution to be tested and of the standard are made, varying the amount of the unknown until two or more successive injections raise the blood-pressure to the same height, indicating that the amount of active agent is the same in the doses used. From the results thus obtained, the strength of the unknown solution may be determined and adjusted." *U. S.*

Beckwith (*J. A. Ph. A.*, 1914, iii, 293) found that the commercial solution of adrenalin chloride, if protected against light and heat in the original container, will retain its activity for a long period of time. If the stopper is removed, however, the air will exercise a destructive oxidation upon the adrenalin. This is evidenced by change of color as to pink, then red and finally brown. Solutions having more than a slight pinkish tint should not be dispensed. Beckwith found that the non-oxidizing mineral acids—such as hydrochloric or sulphuric—had a protective rather than destructive effect. Among the more important incompatibilities he mentions iron, iodine and mercuric chloride.

For other incompatibilities and for medical uses of this solution see *Epinephrina.*

Dose, five to fifteen minims (0.3–1. cc.).

LIQUOR EPISPASTICUS. Br.

BLISTERING LIQUID

Linimentum Cantharidis; Liqueur Vésicant, Huile de Cantharides térébenthinée, *Fr.;* Spanischfliegenliniment, Blasenziehende Flüssigkeit, *G.*

"Cantharidin, 4 *grammes;* Castor Oil, 25 *millilitres;* Resin, 12 *grammes.* Acetone sufficient to produce 1000 *millilitres.* Dissolve. This Blistering Liquid contains approximately the same proportion of Cantharidin as the corresponding preparation of the British Pharmacopœia, 1898." *Br.*

This liquid is used in making the Blistering Collodion. (See *Collodium Vesicans.*) Greenish and Wilson propose that the official blistering liquid be prepared by the following formula. Cantharidin, 1 part; castor oil, 6 parts; rosin, 3 parts; acetic ether, enough to make 300 fluid parts. The castor oil and rosin are added to replace the natural fat of the cantharides, and are necessary to aid the absorption of the cantharides by the skin. (*P. J.*, 1898, 259.)

Off. Prep.—Collodium Vesicans, *Br.*

LIQUOR ETHYL NITRITIS. Br.

SOLUTION OF ETHYL NITRITE

"Solution of Ethyl Nitrite contains not less than 2.5 or more than 3 per cent. by weight of ethyl nitrite in a mixture of ninety-five parts by volume of Absolute Alcohol with five parts by volume of Glycerin. The ethyl nitrite may be obtained by the interaction of alcohol (90 per cent.), sodium nitrite, and diluted sulphuric acid, at a low temperature. Solution of Ethyl Nitrite should be stored in small bottles." *Br.*

Soluté de Nitrite d'Ethyle, *Fr.;* Aethylnitritlösung, *G.*

This was a new official preparation in the Br. Ph., 1898; it might be called improved spirit of nitrous ether; it is difficult to explain the reason for its introduction without the dismissal of spirit of nitrous ether; the strength is very slightly greater than that of the British spirit (less than the U. S. spirit of nitrous ether), and a choice should be made between them. The addition of glycerin as a preservative and the substitution of absolute alcohol for rectified spirit, are relied upon to make a permanent solution. This method was proposed by Dunstan and Dymond (*P. J.*, 1888, 861), who believe that ethyl nitrite is the sole valuable constituent in spirit of nitrous ether; glycerin prevents loss of the very volatile ethyl nitrite, while the absence of water is secured by the use of absolute alcohol, water in the alcohol being shown to be the principal cause of decomposition and loss of ethyl nitrite. Solution of ethyl nitrite was strongly recommended by Leech, and the advantage claimed for it is that it is free from aldehyde. The increased cost, due to the use of absolute alcohol, will be apt to prevent the extensive use of the solution.

It is described as "a nearly colorless transparent liquid, of characteristic apple-like odor and taste. Specific gravity 0.823 to 0.826. When poured on an acidified strong solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids. Does not effervesce when shaken with *sodium bicarbonate* (absence of acid). 10 millilitres, mixed with 5 millilitres of *N/1 solution of sodium hydroxide* and 5 millilitres of *water,* do not assume a yellow color (absence of acetaldehyde). 1 volume, shaken briskly at intervals during five minutes in a brine-charged nitrometer with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid,* yields at 15.5° C., and normal pressure, not less than 6.5 or more than 7.8 volumes of nitric oxide gas." *Br.*

This preparation affords a means of giving ethyl nitrite internally.

Dose, from twenty to sixty minims (1.3–3.75 cc.). (See *Spiritus Ætheris Nitrosi.*)

LIQUOR FERRI CHLORIDI. U. S. (Br.)

SOLUTION OF FERRIC CHLORIDE Liq. Ferr. Chlor. [Solution of Iron Perchloride]

"Solution of ferric chloride contains ferric chloride [$FeCl_3$], corresponding to not less than 10 per cent. nor more than 11 per cent. of Fe." *U. S.*

"This Solution contains 20 grammes of Iron in 100 millilitres; 110 minims contain 20 grains." *Br.*

Liquor Ferri Perchloridi Fortis, *Br.;* Liquor Ferri Muriatici Oxydati, Strong Solution of Ferric Chloride, Solution of Chloride of Iron; Chlorure Ferrique dissous, Soluté de Perchlorure de Fer, Chlorure Ferrique liquide, *Fr.;* Liquo-Ferri Sesquichlorati, *P. G.;* Flüssiges Eisenchlorid, Eisenchloridlösung, *G.*, Solucion de Cloruro Ferrico, *Sp.*

The U. S. X does not give any formula for preparing this solution; that of the Br. is as follows:

"Iron, 70 *grammes;* Hydrochloric Acid, 410 *millilitres;* Nitric Acid, 30 *millilitres;* Distilled Water, *a sufficient quantity.* Place the Iron in a flask; add a mixture of two hundred and fifty millilitres of Hydrochloric Acid and one hundred and forty millilitres of Distilled Water; expose to a moderate temperature until effervescence ceases; then boil; filter from undissolved Iron; rinse the flask and contents with a little Distilled Water; pour the rinsings over the filter; add to the filtrate one hundred and forty millilitres of Hydrochloric Acid; mix; pour the solution in a slow continuous stream into the Nitric Acid, chemical action being promoted if necessary by gently warming; evaporate the product until a precipitate begins to form; add twenty millilitres of Hydrochloric Acid, and sufficient Distilled Water to produce three hundred and fifty millilitres, or to make the resulting Solution respond to the following tests." *Br.* (See below.)

The U. S. P. strength is from 10 to 11 per cent. The British preparation contains 20 per cent. of iron. By the reaction between the hydrochloric acid and the iron, ferrous chloride is produced, which by the subsequent agency of the hydrochloric and nitric acids is converted into ferric chloride, or, as it is denominated in the British Pharmacopœia, perchloride of iron, this being retained in solution by the water with the excess of acid. This excess of acid is limited by a special test in the U. S. P., because too great excess would complicate other formulas in which the tincture is used, such as the tincture of ferric citro-chloride.

When iron is treated with hydrochloric acid there is a copious evolution of hydrogen, and an emerald-green solution of ferrous chloride ($FeCl_2$) results. Green crystals having the composition $FeCl_2,4H_2O$ separate if the solution is permitted to rest. Formerly the nitric acid was added to the solution; now the order is reversed, to prevent frothing. The reaction between the acids and the solution may be thus expressed:

$$\underset{\text{Ferrous chloride.}}{6FeCl_2} + \underset{\text{Nitric acid.}}{2HNO_3} + \underset{\text{Hydrochloric acid.}}{6HCl} =$$

$$\underset{\text{Ferric chloride.}}{6FeCl_3} + \underset{\text{Nitrogen dioxide.}}{N_2O_2} + \underset{\text{Water.}}{4H_2O}$$

If the solution should have a dark color, and not a clear ruby-red, it is due to the presence of a nitro-compound composed of a portion of ferrous chloride and nitrogen dioxide, $FeCl_2 + N_2O_2$. As this compound is easily decomposed, all that is necessary is to heat the liquid and add a few drops of nitric acid, when the dark color soon disappears, nitrogen dioxide is liberated, and a ruby-red solution remains. Any excess of nitric acid is to be evaporated. The final addition of hydrochloric acid is to compensate for any loss which may have been suffered by heating the solution, and to secure an excess of the acid in the finished preparation; otherwise a reddish-brown deposit of oxychloride would gradually form, and precipitation would result upon dilution with alcohol in making the official tincture.

The use of chlorine instead of nitric acid for converting the ferrous chloride to the ferric condition is advocated by C. W. Weiss (*N. R.*, 1883, p. 247), and J. W. England devised a process, based upon such substitutions. (See *U. S. D.*, 19th ed., p. 714.)

Description and Physical Properties.—"A yellowish-brown liquid, having a faint odor of hydrochloric acid and an acid reaction. It is miscible in all proportions with alcohol. Specific gravity: from 1.29 to 1.32 at 25° C. An aqueous dilution of the Solution (1 in 10) responds to the reactions for ferric iron, and for chlorides.

"Weigh about 4 cc. of the Solution, dilute to 100 cc. with distilled water, and precipitate the iron completely by adding an excess of ammonia T.S., and filter: the filtrate is colorless. One-half of the filtrate does not yield a precipitate with hydrogen sulphide T.S. (*zinc, lead, or copper*). The residue obtained upon evaporation and ignition of the remaining half of the filtrate does not exceed 0.1 per cent. (*salts of the fixed alkalies*). Mix 1 cc. of the solution with 10 cc. of ferrous sulphate T.S., and superimpose the mixture upon 5 cc. of sulphuric acid contained in a test tube: the line of contact does not assume a brown or reddish-brown color (*nitrate*). Add a few drops of freshly prepared potassium ferricyanide T.S. to an aqueous dilution of the Solution (about 1 in 20): a brown color is produced which does not at once turn green or greenish-blue (*ferrous salts*). Add 10 cc. of distilled water and 50 cc. of tenth-normal silver nitrate to about 0.5 Gm. of Solution of Ferric Chloride, accurately weighed, shake vigorously then add 2 cc. of nitric acid and sufficient distilled water to measure exactly 100 cc., and mix well. Pass the mixture through a filter not previously moistened (rejecting the first 10 cc. portion), and determine the excess of silver nitrate in 50 cc. of the filtrate by titration with tenth-normal potassium thiocyanate. The percentage of chlorine found is not less than 3 per cent. and not more than 5 per cent. in excess of that required to combine as ferric chloride with the iron present. The percentage of iron (see Assay below) multiplied by 1.9 gives the percentage of chlorine combined at ferric chloride (*free hydrochloric acid*). Each cc. of tenth-normal silver nitrate corresponds to 0.003546 Gm. of Cl.

"**Assay.**—Transfer about 2 Gm. of Solution of Ferric Chloride to a tared flask, stopper, weigh accurately, add 5 cc. of hydrochloric acid, 25 cc. of distilled water and about 3 Gm. of potassium iodide. Securely stopper the flask, and allow the mixture to stand for thirty minutes as a temperature of 40° C. Cool the liquid, dilute it with 100 cc. of distilled water, and then titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe.

"Preserve in glass-stoppered bottles, protected from light." *U. S.*

"An orange-brown solution with a strong styptic taste. Miscible with *water* and with *alcohol* (90 per cent.) in all proportions. Specific gravity about 1.49. Yields the *reactions* characteristic of ferric salts and of chlorides. Yields no characteristic *reactions* for lead, copper, zinc, calcium, sodium, potassium, ammonium, or ferrous salts. On adding a clear crystal of *ferrous sulphate* to a cooled mixture of equal volumes of *sulphuric acid* and of the Strong Solution diluted with nine times its volume of *water* the crystal does not become brown, nor does a brownish-black color develop around it (limit of nitrates). *Arsenic limit* 10 parts per million. 5 millilitres diluted with 80 millilitres of water yield, upon the addition of an excess of *solution of ammonia,* a reddish-brown precipitate, which, when well washed and incinerated, weighs 1.42 grammes. This Solution contains 20 grammes of Iron in 100 millilitres; 110 minims contain 20 grains." *Br.*

Water and alcohol unite with it in all proportions. The British preparation (*Liquor Ferri Perchloridi Fortis*) is stronger than the U. S., the sp. gr. of the former being about 1.49 at 15.5° C., of the latter from 1.29 to 1.32 at 25° C. It should be remembered, however, that there is in the British Pharmacopœia, another solution of ferric chloride which is weaker; it has the sp. gr. 1.110 and is termed *Liquor Ferri Perchloridi.*

Uses.—This preparation is interesting as having led Pravaz to the invention of a syringe—which was the forerunner of the modern hypodermic—for the purpose of injecting solution of ferric chloride in the destruction of *nevi* and other vascular tumors through the precipitation of the blood. This treatment, however, has largely passed out of vogue because of the danger of emboli being carried to other parts. The drug is, however, a very powerful astringent and styptic and is useful for arresting *hemorrhages* from cut surfaces or wounded vessels which it does by causing the formation of a hard coagulum by precipitation of proteins.

It is, in itself, rarely employed as an internal remedy but is the basis for the very popular tincture of ferric chloride. Garrett (*B. M. J.,* 1913, i) recommends the stronger solution of iron chloride Br. as a local application in *ringworm* of the scalp; he states that it must be applied full strength to get good results. Zeissl has used it as a local remedy in *acne rosacea.* Bourget has employed a gelatinized solution of ferric chloride in the treatment of *gastric ulcer.* (*Th. M.,* 1909, p. 353.) His solution consists of 100 grammes each of gelatin, glycerin, and water, and 50 grammes of the *liquor ferri perchloridi,* P. G.

Dose of the U. S. preparation, one to five minims (0.06–0.3 cc.).

Off. Prep.—Liquor Ferri Perchloridi, *Br.;* Tinctura Ferri Chloridi, *U. S.* (*Br.*)*;* Gossypium Stypticum, *N. F.;* Tinctura Ferri Chloridi Ætherea, *N. F.;* Tinctura Ferri Citro-chloridi, *N. F.*

LIQUOR FERRI ET AMMONII ACETATIS. U. S.

SOLUTION OF IRON AND AMMONIUM ACETATE

Liq. Ferr. et Ammon. Acet. [Basham's Mixture]

"Solution of Iron and Ammonium Acetate contains, in each 100 cc., ammonium acetate corresponding to not less than 0.6 Gm. and not more than 0.8 Gm. of NH_3, and not less than 0.16 Gm. and not more than 0.20 Gm. of Fe." *U. S.*

Mistura Ferri et Ammonii Acetatis, *U. S. P.* 1880; Mistura Bashami.

"Tincture of Ferric Chloride, 40 cc.; Diluted Acetic Acid, 60 cc.; Solution of Ammonium Acetate, 500 cc.; Aromatic Elixir, 120 cc.; Glycerin, 120 cc.; Distilled Water, a sufficient quantity to make 1000 cc. To the solution of ammonium acetate (which must be slightly acid) add, successively, the diluted acetic acid, the tincture of ferric chloride, the aromatic elixir, and the glycerin, and lastly enough distilled water to make the product measure 1000 cc." *U. S.*

It should be borne in mind that this was never intended to be a permanent solution, and in time precipitation and decomposition surely set in although somewhat retarded by the presence of glycerin. Some pharmacists adopt the plan of keeping all the ingredients, except the tincture of ferric chloride and water, mixed together in advance, and when called upon to dispense the solution, to add the proper quantity of tincture and water; this saves time and enables them to dispense a clear solution.

Description and Physical Properties.—"A clear, reddish-brown liquid, having an aromatic odor. Specific gravity: about 1.039 at 25° C. The solution is acid to litmus paper. The Solution yields a blue precipitate with potassium ferrocyanide T.S. No precipitate is produced upon the addition of ammonia T. S. When Solution of Iron and Ammonium Acetate is heated with sodium hydroxide T.S., ammonia is evolved. Add 1 cc. each of sulphuric acid and alcohol to 5 cc. of the Solution, and boil the mixture: ethyl acetate is formed, recognizable by its odor.

"**Assay for Ammonia.**—Transfer to a distilling flask with the aid of distilled water exactly 25 cc. of Solution of Iron and Ammonium Acetate, and add sufficient distilled water to make about 200 cc. Add 20 cc. of 20 per cent. sodium hydroxide solution, and distil about 150 cc., receiving the distillate in 40 cc. of half-normal sulphuric acid. Titrate the excess of acid with half-normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of half-normal sulphuric acid corresponds to 0.008520 Gm. of NH_3.

"**Assay for Iron.**—Transfer to a dish with the aid of a little distilled water exactly 25 cc. of Solution of Iron and Ammonium Acetate. Evaporate to dryness and gently ignite. Heat the residue with 10 cc. of hydrochloric acid, and when all of the iron has dissolved, add 10 cc. of solution of hydrogen dioxide, and evaporate to dryness on a water bath. Add 5 cc. of hydrochloric acid, warm until all is dissolved, and transfer the solution to a glass-stoppered flask with the aid of about 30 cc. of distilled water. Add about 2 Gm. of potassium iodide, allow to stand for thirty minutes at about 40° C., cool, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe." *U. S.*

When freshly made, it is a transparent,

bright red liquid. When cloudy, the absence of sufficient free acid is indicated. The iron is in the form of an acetate, while there is formed, as one of the products of decomposition, a small quantity of ammonium chloride, the larger proportion of ammonium acetate remaining undecomposed.

Basham's mixture is actively chalybeate, and also astringent, and is very largely used in *chronic Bright's disease.* There has arisen a popular superstition that it exercises a curative effect in nephritis, but its value is probably simply that of a hematinic and not superior to other forms of iron.

Dose, from one-fourth to one-half fluidounce (7.5–15 cc.).

LIQUOR FERRI PERCHLORIDI. Br.

SOLUTION OF FERRIC CHLORIDE

Solution of Perchloride of Iron.

"Strong Solution of Ferric Chloride, 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Mix." Br.

This is one-fourth the strength of the *Liquor Ferri Perchloridi* of the Br. Pharmacopœia of 1864, which is the *Liquor Ferri Perchloridi Fortis* of the present edition. (See p 631.) It is of the same ferruginous strength as the British Tincture of Ferric Chloride. The specific gravity of this solution is 1.110, and it may be substituted for the tincture of ferric chloride when alcohol is objectionable, as it has the same strength; it is very astringent.

Dose, from five to fifteen minims (0.3–1.0 cc.), well diluted.

LIQUOR FERRI TERSULPHATIS. U. S. (Br.)

SOLUTION OF FERRIC SULPHATE Liq. Ferr. Tersulph. [Solution of Iron Tersulphate]

"An aqueous solution containing normal ferric sulphate [$Fe_2(SO_4)_3$], corresponding to not less than 9.5 per cent. nor more than 10.5 per cent. of Fe." *U. S.*

Liquor Ferri Persulphatis, *Br.;* Solution of Normal Ferric Sulphate, Solution of Tersulphate of Iron; Solution of Persulphate of Iron; Persulfate de Fer liquide, *Fr.;* Ferrisulfatlösung, Schwefelsaure Eisenoxydlösung, Flüssiges Schwefelsaures Eisenoxyd, *G.*

"Ferrous Sulphate, 500 Gm.; Sulphuric Acid, 96 Gm.; Nitric Acid, Distilled Water, each, a sufficient quantity to make 1000 Gm. Add the sulphuric acid to about 250 cc. of distilled water in a tared, capacious porcelain dish, heat the mixture to nearly 100° C., then add 56 Gm. of nitric acid, and mix well. Divide the ferrous sulphate, coarsely powdered, into four approximately equal portions, and add these portions one at a time to the hot liquid, stirring after each addition until effervescence ceases. When all of the ferrous sulphate is dissolved, if the solution has acquired a black color, add nitric acid, a few drops at a time, heating and stirring until red fumes cease to be evolved, and the solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid, as indicated by the test given below. During the heating add distilled water from time to time to maintain about the original volume. Lastly, add enough distilled water to make the product weigh 1000 Gm. Filter, if necessary." *U. S.*

"Ferrous Sulphate, 400.0 *grammes;* Sulphuric Acid, 37.5 *millilitres;* Nitric Acid, 37.5 *millilitres;* Distilled Water, *a sufficient quantity.* Add the Sulphuric Acid to five hundred *millilitres* of the Distilled Water; dissolve the Ferrous Sulphate in the mixture with the aid of heat; mix the Nitric Acid with one hundred *millilitres* of the Distilled Water; add to this diluted acid, warmed, the solution of Ferrous Sulphate; concentrate by boiling, until, on the sudden disengagement of ruddy vapors, the liquid ceases to be black and acquires a red color. If any ferrous salt remain in the solution, add a few drops of Nitric Acid, and boil again. When the solution is cold add, if necessary, sufficient Distilled Water to produce five hundred and fifty *millilitres.*" *Br.*

The ferrous sulphate is preferably in clear crystals, meaning by this "not effloresced," because when the crystals are coated with a whitish powder they have lost water of crystallization, and the proportion of iron present is variable. The nitric acid in the process gives up enough of its oxygen to convert it entirely into ferric sulphate, and the effervescence is owing to the escape of nitrogen dioxide; this becomes red nitrogen tetroxide by contact with the air. The conversion of the ferrous salt into ferric salt is incomplete until the effervescence ceases, and the color, instead of black, as it was at first, has become reddish-brown. Indeed, in order to convert the whole into ferric sulphate it is necessary to continue the heat until nitrous odor ceases to be evolved and thus the entire absence of nitric or nitrous acid from the solution is insured. In consequence of the higher oxidation of the iron the sulphuric acid of the sulphate is insufficient to saturate it. Enough sulphuric acid, therefore, is added to meet this demand. The process is completed by adding enough water to make a definite weight. The U. S. and British formulas are the same in principle.

Description and Physical Properties.—"A reddish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction. Solution of Ferric Sulphate is miscible with water and alcohol. Specific gravity: about 1.432 at 25° C. Solution of Ferric Sulphate responds to the reactions for ferric iron, and for sulphates.

"Mix 1 cc. of the Solution with 10 cc. of ferrous sulphate T.S. and superimpose it upon 5 cc. of sulphuric acid contained in a test tube; the line of contact does not assume a brown or brownish-black color (*nitrate*). Add a few drops of freshly prepared potassium ferricyanide T.S. to 2 cc. of an aqueous dilution of the Solution (1 in 20); a brown color is produced without a tinge of green or greenish-blue (*ferrous salt*).

"**Assay.**—Transfer about 1.5 Gm. of Solution of Ferric Sulphate to a tared flask, stopper and weigh accurately, then add 5 cc. of hydrochloric acid, 25 cc. of distilled water, and 2 Gm. of potassium iodide, securely stopper the flask, and allow the mixture to stand for thirty minutes at a temperature of 40° C. Cool the liquid, dilute it with 50 cc. of distilled water, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.005584 Gm. of Fe." *U. S.*

"A dark-red solution. Inodorous; very astringent. Miscible in all proportions with *alcohol* (90 per cent.) and *water*. Specific gravity about 1.441. Yields the *reactions* characteristic of ferric salts and of sulphates. Yields no characteristic *reactions* for ferrous salts. *Arsenic limit* 5 parts per million. 5 millilitres diluted with 80 millilitres of *water* yield, upon the addition of excess of *solution of ammonia*, a precipitate which, when well washed and incinerated, weighs 1.04 grammes." *Br.*

Uses.—This solution, though powerfully astringent, is too irritant for general use. The chief employment of it is in making other ferruginous preparations in which the ferric hydroxide is wanted, and it should always be kept on hand for the quick preparation of the antidote to arsenic.

LIQUOR FORMALDEHYDI. U. S., Br.

SOLUTION OF FORMALDEHYDE Liq. Formaldehyd.

"An aqueous solution containing not less than 37 per cent. by weight of CH_2O or $H.CHO$ (30.02), with variable amounts of ethyl or methyl alcohol to prevent polymerization." *U. S.* "Solution of Formaldehyde is an aqueous solution containing in 100 millilitres not less than 36 and not more than 38 grammes of formaldehyde, CH_2O. Formaldehyde may be obtained by the limited oxidation of methyl alcohol." *Br.*

Formol, Formalin; Soluté d'Aldehyde Formique, *Fr.;* Formaldehydum solutum, *P. G.;* Formaldehydlösung, *G.;* Formol, *Sp.*

Preparation.—*Formaldehyde* was first prepared in 1868 by Hofmann by passing a mixture of air and methyl alcohol vapor over heated platinum, and it is still practically obtained only from the oxidation of methyl alcohol.

Formaldehyde is now manufactured by the process of Orloff in which rectifying columns are used. The igniters, or activators, are masses of platinized asbestos, or asbestos impregnated with silver. The yield by this method is almost equal to the theoretical; the copper method yielding less than half this amount. The conversion temperature is 450° C. The process is automatically regulated so as to deliver a product containing about 40 per cent. of formaldehyde, 14 per cent. of methyl alcohol and the balance water. Formaldehyde has never been prepared directly from methane, although various attempts have been made in this direction. After a certain process of purification, enough water is added to the formaldehyde so obtained to form a 40 per cent. solution; but this solution is not, strictly speaking, a solution of formaldehyde, as the pure formaldehyde polymerizes the moment the temperature rises above 20° C., and it is this property which renders the addition of water or alcohol necessary. Hence the aqueous solution of formaldehyde probably contains some paraformaldehyde and some unconverted methyl alcohol is always present which is allowed to remain because of the preservative effect it has in preventing polymerization. This change which sometimes occurs in commercial solutions of formaldehyde during the winter months is accompanied by the deposition of a white precipitate sometimes occupying a bulk equal to one-half of the original liquid and when it has occurred the only method of restoration is to acidify with sulphuric acid and redistil the liquid. The commercial products are always aqueous solutions, the common strength being the 37 per cent. solution; a 50 per cent. solution is not permanent.

Recently formaldehyde has been successfully made by reduction of formic acid. Anhydrous formic acid vapors are conducted over asbestos which has been mixed with zinc oxide and powdered zinc. A zinc salt is first produced which then resolves itself into methyl formate and zinc oxide. The methyl formate is subsequently decomposed into methyl alcohol and formaldehyde. (*Ph. Wb.*, 1919, lvi, 406.)

Description and Physical Properties.—"A clear, colorless or nearly colorless liquid, having a pungent odor. Its vapor irritates the mucous membrane of the throat and nose. On long standing, especially in the cold, Solution of Formaldehyde sometimes becomes cloudy, due to the separation of paraformaldehyde. It is miscible with water and alcohol.

"Dilute 2 cc. of Solution of Formaldehyde with 10 cc. of distilled water in a test tube, and add 1 cc. of silver ammonium nitrate T.S.; metallic silver is produced either in the form of a finely divided gray precipitate, or as a bright metallic mirror on the sides of the test tube. Add 2 drops of Solution of Formaldehyde to 5 cc. of sulphuric acid in which about 0.02 Gm. of salicylic acid has been dissolved, and warm the liquid very gently; a permanent, deep red color appears. Not more than 1 cc. of normal sodium hydroxide is required to neutralize 20 cc. of Solution of Formaldehyde, using 2 drops of phenolphthalein T.S. as indicator (*free acid*).

"**Assay.**—Transfer 3 cc. of Solution of Formaldehyde to a tared flask containing 10 cc. of distilled water, tightly stopper, and weigh accurately. Add 50 cc. of normal sodium hydroxide, and follow this immediately but slowly through a small funnel with 50 cc. of hydrogen dioxide T.S. which has previously been rendered neutral to litmus T.S. with sodium hydroxide T.S. Heat the mixture cautiously on a water bath for five minutes, shaking it occasionally. Allow the mixture to cool, rinse the funnel and sides of the flask with distilled water, and, after allowing it to stand thirty minutes, titrate with normal sulphuric acid, using litmus T.S. as indicator. Each cc. of normal sodium hydroxide corresponds to 0.03002 Gm. of H.CHO.

"Preserve in a moderately warm place, protected from light." *U. S.*

"A colorless liquid with a characteristic, pungent odor. Neutral or slightly acid to *litmus*. Miscible with *water* and with *alcohol* (90 per cent.) in all proportions. Caustic when applied to the skin. Specific gravity 1.079 to 1.081. Yields, when evaporated to dryness, a whitish, amorphous residue which leaves no appreciable ash on incineration. Yields with *solution of silver ammonio-nitrate* a precipitate of metallic silver. On the addition of 2 drops of the Solution to 5 millilitres of *sulphuric acid*, in which a little *salicylic acid* has been previously dissolved, a deep red coloration is produced. When 1 millilitre is mixed with 10 millilitres of *N/10 solution of iodine*, the mixture nearly decolorised with *solution of sodium hydroxide* and warmed, no yellow, crystalline precipitate is produced (absence of acetone). Diluted with four times its volume of *water* it yields no characteristic *reactions* for iron, copper, lead, calcium, chlorides, or sulphates. Contains in 100 millilitres not less than 36 and not more than 38 grammes of formaldehyde, CH_2O, as determined by the following process:—To 50 millilitres of *N/1 solution of sodium hydroxide* add 3 millilitres of Solution of Formaldehyde and 50 millilitres of *solution of hydrogen peroxide* and warm on a water-bath; similarly mix 50 millilitres of *N/1 solution of sodium hydroxide* with 50 millilitres of *solution of hydrogen peroxide* and warm on a water-bath. When the reactions are complete and all effervescence has ceased, add a few drops of *solution of phenolphthalein* to each mixture and titrate with *N/1 solution of sulphuric acid*. The difference between the two titrations is not less than 36 and not more than 38 millilitres." *Br.*

Formaldehyde may be determined in aqueous solutions by treatment with excess of standard ammonia, which converts it into hexamethylenamine. The excess of ammonia may then be titrated with standard acid. The mixture of the formaldehyde solution and ammonia should stand for at least twelve hours. This method, however, has not been found in practice to be as accurate as the hydrogen dioxide method, which was therefore chosen by the Revision Committee as the basis of the official assay process. In this method standard sodium hydroxide is used in connection with hydrogen dioxide, the reaction being as follows: $2CH_2O + 2NaOH + H_2O_2 = H_2 + H_2O + 2HCO.ONa$.

Because of the use of formaldehyde as a preservative of milk and food products the detection of small amounts of it is a matter of great importance. Several of the tests proposed are primarily applicable to milk only, being based on reactions which take place in the presence of milk proteids, so that if these tests are to be applied in testing other liquids for the presence of formaldehyde, the material must be mixed with an equal quantity of milk which has been shown previously to be free from formaldehyde. The principal tests may be divided into two groups, those in which a colored zone is obtained at the junction of two liquids, one of which has been superimposed upon the other, and those in which a color reaction is obtained in the body of the liquid tested. The first group includes the resorcinol-sulphuric acid test, the phenol-sulphuric acid test, and the sulphuric acid test of Hehner (carried out in the presence of milk). The method of application of the two tests first mentioned is as follows: To 5 cc. of the liquid to be tested, one or two drops of a one per cent. aqueous solution of phenol or resorcinol are added, and this liquid is then allowed to bow gently down the inside of the test tube containing 2 or 3 cc. of the sulphuric acid so as to form a layer above the acid without mixing. In the presence of formaldehyde a rose-colored zone is produced in extreme dilution, or in more concentrated solutions an opaque pinkish zone above the rose-colored one. In the Hehner test, the liquid to be tested is mixed with an equal volume of formaldehyde-free milk, and this mixture is allowed to flow down the inside of the test tube upon 2 or 3 cc. of commercial sulphuric acid containing a trace of ferric chloride. A violet zone is formed in the presence of formaldehyde. The general color tests constituting the second group of tests are the phenylhydrazine test with its modifications, the phloroglucinol test, the resorcinol-soda test, and the hydrochloric acid test. (A full discussion and comparison of these tests by C. H. LaWall will be found in *Am. Drug.*, 1905, vol. xlvii, p. 33.)

The foregoing tests are all group tests for aldehydes and positive results will be obtained in the presence of furfurol, vanillin, and many other aldehydic bodies. The best specific test given by formaldehyde only is that of Rimini, and is carried out as follows: To 10 cc. of the clear liquid or distillate is added 0.05 gramme phenylhydrazine hydrochloride followed by 3 drops of a 5 per cent. aqueous solution of sodium nitroprusside, and, finally, by 1 cc. (or an excess) of a 10 per cent. sodium hydroxide solution. In the presence of formaldehyde a blue or greenish-blue color is immediately produced which, however, quickly changes to yellow and finally to red.

The test is so sensitive as to detect the substance in a solution containing but one drop of commercial formaldehyde solution in five gallons of water.

A. B. Lyons (*Proc. A. Ph. A.*, 1905, 326) proposes the use of *beef peptone* in place of milk (except when milk is under investigation) in Hehner's test (see above). He also suggests the use of morphine and sulphuric acid as a test for formaldehyde. (*Proc. A. Ph. A.*, 1905, 329.)

Uses.—Formaldehyde was introduced as a disinfectant by Trillat in 1888. It is remarkable among germicidal agents for the fact that its action in solution is less powerful than as a vapor. Its solutions are about equivalent in germicidal activity to those containing the same percentages of phenol. Burgess (*L. L.*, 1900, i, p. 1797) found that a 2 per cent. solution would kill the *B. coli communis* in five minutes and Slater and Rideal found that it required 50 minutes for a one per cent. solution to destroy various non-sporulating micro-organisms. Its action as an antiseptic, however, far exceeds that of phenol. In Slater and Rideal's experiments one part in five thousand absolutely inhibited and one in twenty thousand greatly restrained the growth of bacteria. As regards the effects of formaldehyde vapor, it has been shown that as little as one part in three thousand parts of air will destroy many bacteria, and, according to Kenwood, one or two per cent. will rapidly disinfect all surfaces. It should be remarked in this connection that the penetrating power of formaldehyde has been usually over-estimated and that bundles of clothing or similar material are not effectually disinfected by such strengths of the gas.

Formaldehyde is an intense local irritant both to mucous membranes or if in sufficient concentration, to the skin. In strong solution it precipitates albumen or gelatin, but very minute quantities are asserted to prevent the coagulation of albumen by heat. When injected into the circulation in such dilutions as not to precipitate the proteins of the blood, or after its absorption through the gastro-intestinal mucosa, it exercises relatively slight effects on the vital functions. According to McGuigan (*J. A. M. A.*, 1914, lxii, p. 984), large quantities lower the blood pressure by a direct action upon the heart and vessel walls. Fleig states that it causes contraction of the renal vessels. It is rapidly oxidized in the system and appears in the urine as formic acid, so that after the administration of even relatively large doses no formaldehyde can be found in the excretions.

Formaldehyde is used in medicine chiefly for its disinfectant properties. Because of its local irritant influence it is rarely of service as a surgical application to the living body. It is occasionally used for the disinfection of surgical instruments and apparatus. For this purpose the vapor is more efficient than the solution. The most important use of formaldehyde is for the disinfection of rooms and various objects like books which might be injured by steam. Although it has a powerful effect on some forms of organic matter, things which are likely to come in contact with patients suffering from infectious diseases, such as clothing and the decorations in the sick room, are not injured by disinfectant strengths. Because of its affinity for ammonia and for hydrogen sulphide it has strong deodorizing properties. Various methods for the vaporization of formaldehyde are used in room disinfection; these include (1) direct generation by oxidizing methyl alcohol; (2) spontaneous evaporation of a solution sprinkled around the room; (3) evaporation of the official solution by means of heat; (4) vaporization of the official solution by oxidizing agents; and (5) decomposition of its polymer known as paraform. The first of these has been largely abandoned because of its cumbersomeness and the uncertainty of amount, the second because of its inefficiency and injurious effect upon the operators. The decomposition of paraform by heat is a convenient method for disinfecting small spaces, such as boxes containing surgical appliances, or closets, but is too expensive for general use; moreover, the presence of considerable amounts of aqueous vapor in the air is essential for best results with formaldehyde, and in most of the apparatuses using paraform insufficient provision is made for this. The method of evaporating aqueous solutions of formaldehyde with heat is the basis of a number of efficient apparatuses, but it is doubtful whether these have any real advantage over the cheap and handy method of volatilizing by means of oxidizing agents. The substances which have been used for the latter service include potassium permanganate, quick lime, barium peroxide, and sodium dichromate. The method recommended by the Pennsylvania State Board of Health (Dixon, *A. J. P.*, July, 1912) is as follows: For a thousand cubic feet of air space, one pint of the official solution of formaldehyde and eight ounces of potassium permanganate. Place the potassium permanganate in a bucket with at least ten times the capacity of the amount of disinfectant. Pour the formaldehyde on the permanganate. Eighty per cent. of the formaldehyde is liberated in the first five minutes. Doerr recommends the proportion of one part each of potassium permanganate, formaldehyde solution, and water. Hall and Roberts assert that seven parts of potassium permanganate to ten of formaldehyde solution is the most economical; this gives a liberation of 63 per cent. of the total formaldehyde. If water is added the percentage of liberation is lower, but the water is advantageous in aiding the disinfectant properties. It should be remembered that with careless use there is a possibility of setting fire to the room. In 1914, owing to the scarcity of potassium permanganate caused by the European war, a method was devised by LaWall (*J. A. M. A.*, 1914, lxiii, 1025) in which sodium dichromate takes the place of potassium permanganate. Notwithstanding some criticism of this process, as destroying a larger amount of the formaldehyde than the potassium permanganate method, tests made by the Pennsylvania Health Department bacteriologist, working under conditions such as are actually encountered in practical disinfection work, show all bacteria to be killed when the directions are carefully followed.

Inhalations of formaldehyde vapors have been tried in the treatment of pulmonary disorders, notably *phthisis,* with the idea of direct destructive action upon the bacteria, but they are so irritant to mucous membranes that the treatment has done more harm than good. Formaldehyde is also of service for the purpose of hardening the skin and of stopping excessive sweating in various forms of *hyperidrosis.* For this use the official solution should be diluted with from one to three parts of water. Hammond (*Am. Med.,* 1912, xviii, p. 391) has used formaldehyde with asserted success as a caustic in removal of *warts, corns, moles,* etc; he applies the full strength official solution four or five times a day for two or three days, being careful not to get it on the healthy skin. It is used in pharmacy for hardening gelatin capsules. (See under *Gelatinum.*)

Although its physiological action is comparatively slight, yet when swallowed it is a dangerous poison on account of its local irritant effects. The symptoms of formaldehyde poisoning are immediate severe abdominal pains with blood-stained vomiting, general collapse often with loss of consciousness, and albuminous, bloody or suppressed urine. Out of ten cases collated by McLoughlin (*Cleveland Med. Journ.,* 1909) three ended fatally. The smallest fatal dose of which we have any knowledge is the case reported by Eli (*J. A. M. A.,* liv) in which "a few drops of a 40 per cent. solution of formaldehyde" killed a three-year-old child with symptoms of edema of the larynx. The ordinarily fatal dose for an adult is about three fluidounces of the official solution. The diagnosis is usually easy from the odor of formaldehyde in the vomitus. The treatment requires an immediate evacuation of the stomach, the use of dilute ammonia water as an antidote, subsequently demulcents and symptomatic remedies as they may be indicated.

Festiform is a solution of formaldehyde solidified by the addition of soap. *Autan* is a mixture of paraform and barium peroxide which in the presence of water liberates formaldehyde gas. *Formysol* is a formalized soft soap as is also *veroform. Lysoform* is another saponaceous mixture containing formaldehyde.

Off. Prep.—Liquor Formaldehydi Saponatus, *Br.*

LIQUOR FORMALDEHYDI SAPONATUS. Br.

SOLUTION OF FORMALDEHYDE WITH SOAP

"Soft soap, 400 *grammes;* Alcohol (90 per cent.), 300 *millilitres;* Solution of Formaldehyde, 200 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve the Soft Soap in the Alcohol; add the Solution of Formaldehyde and sufficient Distilled Water to produce the required volume." *Br.*

LIQUOR HAMAMELIDIS. Br.

SOLUTION OF HAMAMELIS

Aqua Hamamelidis, *N. F.;* Witch Hazel Water; Distilled Extract of Witch Hazel; Witchhazel extract; Eau distillée de hamamelis, *Fr.;* Hamameliswasser, *G.*

"Fresh Hamamelis Leaves, 1000 *grammes;* Distilled Water, 2000 *millilitres;* Alcohol (90 per cent.), 160 *millilitres.* Macerate for twenty-four hours; then distil one thousand *millilitres.*" *Br.*

This preparation is no longer recognized by the U. S. but a similar one is official in the N. F. (see *Aqua Hamamelidis,* Part III).

Uses.—This water was introduced on account of the large demand for it which has grown out of the wide advertisements of a certain proprietary medicine, and the universally recognized need in American families for an embrocation which appeals to the psychic influence of faith. As the tannic acid of hamamelis bark does not come over into the distillate the water is therapeutically a mixture of water and alcohol, the volatile oil being found in too minute a proportion to possess any therapeutic value.

LIQUOR HYDRARGYRI NITRATIS ACIDUS. Br.

ACID SOLUTION OF MERCURIC NITRATE

Liquor Hydrargyri Nitratis, *N. F.;* Solution of Mercuric Nitrate; Solution of Nitrate of Mercury; Solution of Pernitrate of Mercury; Liquor Hydrargyri Nitrici Oxydati; Azotate Mercurique liquide, *Fr. Cod.;* Deutazotate (Pernitrate) de Mercure liquide, *Fr.;* Mercurnitratlösung, Quecksilberoxydnitratlösung, Flüssiges Salpetersaures Quecksilberoxyd, *G.*

"Mercury, 120 *grammes;* Nitric Acid, 150 *millilitres;* Distilled Water, 45 *millilitres.* Mix the Nitric Acid with the Distilled Water in a tared flask; dissolve the Mercury in the mixture without the application of heat; then boil gently until the Solution weighs three hundred and sixty *grammes.* Preserve it in a stoppered bottle not exposed to the light." *Br.*

The N. F. recognizes a very similar solution (see Part III).

In the British process, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid mercuric nitrate, which is brought to a determinate bulk by evaporation. The proportion of nitric acid is sufficient not only to form mercuric nitrate, but also to furnish a large excess of acid.

Properties.—Solution of mercuric nitrate is a clear, nearly colorless, heavy liquid, having a faint odor of nitric acid, and a strongly acid reaction. "Specific gravity about 2.0. Yields no characteristic *reaction* for mercurous salts." *Br.*

Mercuric nitrate, the salt present in this preparation, can be obtained in large crystals of the composition $Hg(NO_3)_2 + 4H_2O$, when its solution is allowed to evaporate slowly over sulphuric acid. The same salt, which is very deliquescent, is obtained as a crystalline magma by adding strong nitric acid to the concentrated solution.

Uses.—This preparation is used as a caustic application to *cancers, lupus, ulcerations* of the *cervix, chancres,* etc. When a very free use is desired, it may be applied to the diseased surface by a camel's-hair brush, or cotton applicator. In *acne* and *boils* a drop, proportioned in size to the pustule, applied to the apex is sometimes of service. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic. It is not used internally.

LIQUOR HYDRARGYRI PERCHLORIDI. Br.

SOLUTION OF MERCURIC CHLORIDE

Liquor Hydrargyri Bichloridi; Solution of Bichloride of Mercury; Solution of Corrosive Sublimate; Sublimatlösung, *G.*

"Mercuric Chloride, 1 *gramme;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve. This Solution should be kept protected from light. 100 *millilitres* contain 0.1 gramme of Mercuric Chloride; 110 minims contain 1/10 grain." *Br.*

This solution may be used as affording a convenient method of exhibiting corrosive sublimate. The ammonium chloride formerly used (Br.Ph., 1885) to aid in dissolving the mercuric chloride has been omitted in the process of the Br. Ph., 1914.

Dose, from one-half to one fluidrachm (1.8–3.75 cc.).

LIQUOR HYDROGENII DIOXIDI. U. S. (Br.)

SOLUTION OF HYDROGEN DIOXIDE Liq. Hydrog. Diox. [Solution of Hydrogen Peroxide]

"Solution of Hydrogen Dioxide is an aqueous solution containing not less than 3 per cent. by weight of H_2O_2." *U. S.*

"Solution of Hydrogen Dioxide is an aqueous solution containing not less than 3 per cent. by weight of H_2O_2, corresponding to not less than 10 volumes of available oxygen." *U. S.* "Solution of Hydrogen Peroxide is an aqueous solution of hydrogen peroxide, H_2O_2, prepared by the interaction of water, barium peroxide, and a dilute mineral acid, at a temperature below 10° C." *Br.*

Liquor Hydrogenii Peroxidi, *Br.;* Solution of Hydrogen Peroxide; Aqua Hydrogenii Dioxidi, Oxygenized Water, Oxygen Hydrate; Péroxide d'Hydrogene; Solutio Hydrogenii Peroxydati, *Fr. Cod.;* Wasserstoffhyperoxyd, Wasserstoffhyperoxidlösung, *G.;* Hydrogenium Peroxydatum Solutum, *P. G.;* Acqua ossigenata, *It.;* Agua oxigenada, *Sp.*

The U. S. P., 1890, process (see *U. S. D.,* 18th edition, p. 214) consisted in the decomposition of barium dioxide by phosphoric acid, barium phosphate being thrown down as a precipitate, hydrogen dioxide being found dissolved in the supernatant aqueous liquid; the barium phosphate is filtered out, and any trace of barium salt is finally removed by the cautious addition of sulphuric acid, which precipitates it as insoluble barium sulphate; the very fine precipitate which usually passes through the pores of filter paper is caught and held on the filter by the starch, and the clear solution may be adjusted to contain 3 per cent., *by weight,* of absolute hydrogen dioxide by assay.

Commercially it is usually made by a process essentially the same as that given above, the phosphoric acid being regenerated from the precipitate of barium phosphate by the addition of sulphuric acid which converts it into insoluble barium sulphate with the liberation of almost the original amount of phosphoric acid used. Another method is also used in which hydrofluoric acid is employed. This yields the comparatively insoluble barium fluoride as a by-product and the hydrofluoric acid may be regenerated from this also by the use of sulphuric acid. On the large scale it is necessary to reduce the temperature of the reaction by refrigeration of some kind in order to get anywhere near the full theoretical yield from the barium dioxide used. One of the important points is the preliminary hydration of the barium dioxide which is accomplished by allowing the dioxide to stand in contact with an excess of water until it attains a creamy consistence. It may also be prepared by the action of carbon dioxide upon hydrated barium peroxide, under pressure.

It has also been prepared from sodium peroxide as well as from perborates and persulphates. By the latter method concentrations up to 30 per cent. strength have been obtained by simple distillation of persulphuric acid, hydrogen peroxide distils over and leaves the sulphuric acid behind and the latter may again be converted into persulphuric acid by electrical energy.

Pure crystallized 100 per cent. H_2O_2 has been obtained by fractional extraction with ether and removal of the latter under reduced pressure in connection with the use of liquid carbon dioxide for reducing the temperature. Pure H_2O_2 melts at –2° C. It explodes with great violence when brought into contact with certain catalyzers and sets fire to fabrics with which it is brought into contact.

Hydrogen dioxide may be evaporated *in vacuo* at a gradually increasing temperature, a nearly pure hydrogen dioxide coming over at about 84° C. Wolffenstein states that he has prepared, after repeated fractioning, hydrogen peroxide (99.1 per cent.). (See *B. Chem. G.,* 1894, 3307. See also Schiloff's process, *Chem. News,* 1896, 38.) Crystallized hydrogen dioxide has been made by W. Staedel by applying a freezing mixture to a very strong solution of the dioxide, and collecting the separated columnar crystals; it is a very active body, being decomposed with explosive violence on coming in contact with manganese dioxide. (*Ph. Centralh.,* 1902, 546.)

A solidified compound of urea, 1 molecule, and hydrogen peroxide, 1 molecule, stabilized with citric acid is known under the trade names *hyperol* and *perhydrite.* It contains over 30 per cent. H_2O_2. The official solution is strong enough for most practical uses, for, although it can readily be made stronger, the difficulties of preserving it largely increase with its increased strength, and hence the Committee of Revision wisely fixed the standard at *ten volumes of available oxygen.* The British Pharmacopœia requires that the Solution shall indicate a yield of from *nine to eleven volumes* of oxygen when tested by the nitrometer test.

Solution of hydrogen dioxide is a powerful oxidizer and the simple contact with various substances, as platinum, gold and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there are a number of bodies which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies, while some salts, like silver oxide, are actually reduced by it. Traces of impurities modify the stability of hydrogen dioxide; acids increase, alkalies decrease, its stability. Some manufacturers add a certain proportion of oxalic acid to the solution of hydrogen dioxide to raise the apparent value of the product, as shown by the permanganate assay; for a method of detecting this fraud, see a paper by G. Arth (*D. C.,* 1902, p. 141).

Description and Physical Properties.—"A colorless liquid, odorless, or having an odor suggesting ozone. It is slightly acid to the taste and produces a peculiar sensation and froth in the mouth. It is prone to deteriorate upon keeping or upon protracted agitation, and rapidly decomposes by contact with many oxidizing as well as reducing substances. When exposed to the air at the ordinary temperature or when heated on a water bath at a temperature not exceeding 60° C., the Solution loses chiefly water. When rapidly heated, it frequently decomposes suddenly. Solution of Hydrogen Dioxide is acid to litmus paper.

"Shake 1 cc. of Solution of Hydrogen Dioxide with 10 cc. of distilled water containing 1 drop of diluted sulphuric acid, and add 2 cc. of ether; the subsequent addition of a drop of potassium dichromate T.S. produces a blue color in the aqueous layer. Upon agitation and standing, this blue color passes into the ether layer.

"Not more than 0.03 Gm. of residue remains on evaporating 20 cc. of the Solution to dryness on a water bath (*non-volatile matter*). It requires not more than 2 cc. of tenth-normal sodium hydroxide, phenolphthalein T.S. being used as indicator, to neutralize 25 cc. of Solution of Hydrogen Dioxide (*free acid*). Add 1 cc. of ammonia T.S. to 1 cc. of the Solution, and evaporate the liquid to dryness on a water bath: the residue meets the requirements of the test for *arsenic.* Evaporate 1 cc. of the Solution to dryness on a water bath, and dissolve the residue in 10 cc. of distilled water containing 1 cc. of diluted hydrochloric acid: the liquid meets the requirements of the test for *heavy metals.* To 50 cc. of the Solution add sodium hydroxide T.S. until it is alkaline, then evaporate it on a water bath, and transfer the dry residue to a platinum crucible. Moisten the residue with sulphuric acid, and cover the crucible with a watch glass, the convex side of which is coated with a thin layer of bees wax which is scratched so as to expose the glass. Cool the watch glass by placing water in the concave side and standing in this a small beaker which must be kept filled with cold water. Now heat the crucible and contents on a water bath for one hour; the surface of the watch glass after the removal of the wax shows no sign of corrosion (*hydrofluoric acid*). The addition of 2 drops of diluted sulphuric acid to 10 cc. of the Solution produces no turbidity or precipitate within ten minutes (*barium*). Add 4 drops of sodium acetate T.S. to 10 cc. of the Solution, and follow with 4 drops of calcium chloride T.S.; no turbidity or precipitate is produced within ten minutes (*oxalic acid*). Shake out 100 cc. of Solution of Hydrogen Dioxide in a separator with a mixture of 3 volumes of chloroform and 2 volumes of ether, using 50 cc., 25 cc., and 25 cc., respectively, and evaporate the combined solutions to dryness at room temperature in a tared glass dish; the residue, if any, weighs not more than 0.04 Gm. (*limit of preservative*).

"Preserve in a cool place protected from light and dust. If the stopper of the bottle is coated with paraffin or replaced by a pledget of purified cotton, deterioration is retarded," *U. S.*

"**Assay.**—Dilute about 2 cc. of Solution of Hydrogen Dioxide, accurately weighed, with 20 cc. of distilled water, add 20 cc. of diluted sulphuric acid, and titrate with ten-normal potassium permanganate. Each cc. of tenth-normal potassium permanganate corresponds to 0.001701 Gm. of H_2O_2." *U. S.*

"A colorless and odorless liquid. Taste slightly acid. Decomposed by heat into water and oxygen. On adding a few drops to 10 millilitres of *water* mixed with a drop of *solution of potassium chromate,* 10 drops of *diluted sulphuric acid,* and 2 millilitres of *ether,* a blue layer appears between the ethereal and the aqueous liquid, and, after shaking, the *ether* also becomes blue. 2 millilitres vigorously shaken in a brine-charged nitrometer with 4 millilitres of *solution of copper ammonio-sulphate* liberate, at 15.5° C., and normal pressure, not less than 18 and not more than 22 millilitres of oxygen, corresponding to about 10 volumes of available oxygen in 1 volume of the Solution. 25 millilitres require for neutralisation not more than 2.5 millilitres of *N/10 solution of sodium hydroxide, solution of methyl orange* being used as indicator (limit of acidity). Yields no characteristic *reactions* for barium. Evaporated to dryness on a water-bath, not more than 1 per cent. of solid residue remains." *Br.*

F. X. Moerk has proposed a rapid and effective method of assaying this solution (see *A. J. P.*, 1893, 65). Kolthoff (*Ph. Wb.*, 1919, lvi, 949) also reviews the assay methods and suggests one in which ammonium molybdate is used as a catalyzer to liberate iodine from potassium iodide, the titration being made with sodium thiosulphate solution.

Another assay method has been proposed by Von Bertalan (*D. C.*, 1920, lxiv, 340), based on the oxidation of stannous chloride and the reduction of methylene blue to the leuco base.

Solution of hydrogen dioxide should be kept in a cool place, and not too tightly stoppered. (A plug of absorbent cotton is often used.) Neglect of these precautions, particularly in hot weather, will be likely to result in an explosion and fracture of the bottle containing it, due to a brisk evolution of oxygen in a confined space, on account of the increased temperature.

Hydrogen dioxide solution is usually preserved at the present time by the use of acetanilid or some other equally efficacious agent for retarding its decomposition. The presence of acetanilid was first called attention to in pharmaceutical literature by LaWall (*A. J. P.*, 1906, p. 582). Boroglycerin, caffeine, and other substances have also been used for the purpose. When acetanilid is used the solution upon standing for some time occasionally acquires a disagreeable odor due to the formation of nitrobenzene and other decomposition derivatives of the acetanilid. The amount of acetanilid used as a preservative is very small, being about 0.05 per cent. A study of the effect of various preservatives was reported by A. M. Glover (*A. J. P.*, 1913, p. 538), who found acetanilid to be the best of all that were tried. Kolthoff (*loc. cit.*) suggests either phenol, benzoic, or salicylic, acid in the proportion of 100 milligrammes per liter.

It has been claimed that its deterioration is often due to the alkalinity of the glass bottles in which it is stored, and that if alkali-free glass containers be used it will keep for extended periods without a preservative. (*Pharm. Era*, liv, 1921, p. 385.) Jordan (*J. A. Ph. A.*, 1913, ii, p. 344) finds that solutions of hydrogen dioxide kept in bottles stoppered with cotton, instead of a cork, retain their activity very much better, he believes, on account of the evaporation of the water. He also found that bottles protected from the light retained their activity better than those exposed to the light. Most of the samples examined were below pharmacopœial strength. One contained as little as 0.24 per cent. of H_2O_2, but the majority of them ranged from 2.5 to 3 per cent.

Uses.—Hydrogen peroxide in solution undergoes a slow process of reduction liberating a portion of its oxygen. Certain organic matters, however, among which may be mentioned pus and blood, exercise a powerful catalyzing action so that the oxygen is given off very rapidly. Evidently this nascent oxygen must have a powerful oxidizing effect and thereby destroy many forms of organic matter. It should be noted that in the presence of these reducing agents the antibacterial powers of the drug are greatly reduced. As long as there is effervescence caused by the application of hydrogen dioxide to a wound there is no great destruction of bacteria. Upon the system generally hydrogen peroxide does not, and cannot, exert any physiological action, because it cannot exist in the blood.

The most important use for this agent is as an antibacterial agent. The germicidal activity of hydrogen peroxide is generally greatly overestimated. Although in relatively dilute solution it will eventually destroy many of the pathogenic micro-organisms, its action is extremely slow, unless the solution be fairly concentrated. Gifford (*N. Y. M. R.*, 1888) found that a neutral solution containing 15 per cent. by volume of H_2O_2 (therefore stronger than the official solution) would destroy anthrax spores after five minutes' exposure, and pus cocci in one minute, but that the same solution when diluted with four parts of water did not kill the pus cocci after thirty minutes. Traugott found that 1 per cent. by weight killed typhoid bacilli in five minutes and staphylococci in fifteen to thirty minutes. On the other hand, if allowed sufficient time relatively small quantities are highly efficient. Heinemann (*J. A. M. A.*, 1913, lx, p. 1603) reaches the conclusion from his experiments that three teaspoonfuls of the official solution after six hours' exposure will destroy 99 per cent. of the bacteria present in a liter of drinking water; this quantity makes about a one to one thousand solution of hydrogen peroxide. In the presence of organic matter this compound is so rapidly broken down that it is even less efficient; as pointed out by Gifford, its germicidal action does not depend upon the liberated oxygen, but upon the hydrogen peroxide molecule.

The addition of hydrogen dioxide solution has at times been recommended as an emergency method for the preservation of milk. It effects a partial or complete sterilization on the milk and quickly disappears, being dissociated into H_2O and O. A paper dealing with the length of time during which the H_2O_2 persists in the milk has been published in the *Analyst*, 1915, p. 482, by M. E. Hines. The use in milk and cream is common in Great Britain. As it was first suggested by Budd, products so preserved are sometimes called "buddized."

The solution of hydrogen dioxide is used in medicine as a means of cleansing infected *wounds*, freely suppurating *ulcers*, and the like. Its value in these conditions is probably more due to removing organic detritus which forms a breeding place for the micro-organisms than to its antibacterial action. Its styptic effect—probably due to the activation of the fibrin ferment of the blood and consequent more rapid coagulation—as well as its harmless nature make it a very popular antiseptic for household use. It is sometimes injected into deep cavities for the purpose of determining the presence of pus, which will be signalized by effervescence; the method, however, must be used with caution, because if there be not a free vent for the gas sufficient pressure may be generated within the cavity to cause serious results. Because of its lack of toxicity it is a favorite disinfectant for application to various mucous membranes, especially those of the nose and throat. In *diphtheria* or *tonsillitis* the official solution may be applied pure, either by means of an atomizer or cotton applicator. Diluted with equal parts of water it is often employed as a gargle in *pharyngitis,* or as a mouth wash in *stomatitis,* but it appears frequently to exercise an injurious effect upon the epithelium of the buccal mucous membrane. In slow *hemorrhages* it often exercises a styptic effect, perhaps through activating the specific ferments of the blood which lead to clot formation. Internally the solution of hydrogen dioxide has been used with success by Goodman (*Penna. M. J.,* 1910) and others, in the treatment of *hyperchlorhydria.* It is asserted that it diminishes the acidity of the gastric juice, increases the secretion of mucous and exercises an antiseptic action in the stomach.

One great disadvantage of the solution of hydrogen dioxide is the rapidity with which it deteriorates. The New Hampshire State Board of Health reported in 1912 that more than half of the samples examined were below the Pharmacopœial standard.

Solution of hydrogen dioxide is used in 10 or 15 per cent. aqueous solutions, for various commercial purposes, such as cleaning and bleaching old and stained engravings or oil paintings, or as an auricome for bleaching dark colored hair. It is employed, moreover, in increasing degree in the textile industries for bleaching. Lunge has proposed its use in the ready valuation of chlorinated lime or bleaching powder, which is decomposed by it with the simultaneous liberation of oxygen from both substances in equal amount.

Under the name of *perhydrol* a solution asserted to represent 100 volume per cent. (30 per cent. by weight) of hydrogen dioxide is upon the market.

Dose, one fluidrachm (3.75 cc.).

LIQUOR IODI COMPOSITUS. U. S.

COMPOUND SOLUTION OF IODINE Liq. Iodi. Co.
[Lugol's Solution]

"Compound Solution of Iodine is an aqueous solution containing, in each 100 cc., not less than 4.8 Gm. and not more than 5.2 Gm. of I and not less than 9.8 Gm. and not more than 10.2 Gm. of KI." *U. S.*

Liquor Iodinii Compositus, *U. S.* 1870; Soluté ioduré de Lugol, *Fr.;* Lugolsche Jodlösung, *G.*

"Iodine, 5 Gm.; Potassium Iodide, 10 Gm.; Distilled Water, a sufficient quantity, to make 100 cc. Dissolve the iodine and potassium iodide in a sufficient quantity of distilled water to make the product measure 100 cc." *U. S.*

In this solution iodine is dissolved in water with the assistance of potassium iodide. Iodine dissolves sparingly in water, but freely in a solution of this salt. In using potassium iodide to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine, and this is the proportion adopted in the U. S. formula.

In the Br. Pharmacopœia a solution is directed having much more iodine and less potassium iodide than the U. S. solution under the name *Tinctura Iodi Fortis.*

Description and Physical Properties.—"A transparent liquid having a deep brown color, and an odor of iodine. A drop of Compound Solution of Iodine added to 1 cc. of starch T.S., diluted with 10 cc. of water, produces a deep blue color.

"**Assay for Potassium Iodide.**—Measure exactly 5 cc. of Compound Solution of Iodine, evaporate in a tared dish or watch-glass on a water bath, and add several small successive portions of distilled water, drop by drop, until all of the iodine has volatilized and a white residue remains; the residue should weigh not less than 0.490 Gm. and not more than 0.510 Gm. and should respond to the identity tests under *Potassii Iodidum.*

"**Assay for Iodine.**—Dilute exactly 5 cc. of Compound Solution of Iodine with 25 cc. of distilled water, and titrate with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.01269 Gm. of I.

"Preserve the solution in glass-stoppered bottles, protected from light." *U. S.*

Uses.—Doctor Lugol, to whose investigations carried on about 1830 is due chiefly the introduction of iodine as a drug, used solutions of varying strength according to the purpose for which they were employed. His *iodine lotion,* used as a wash in scrofulous *ophthalmia,* in *ozena,* etc., contained two grains of iodine and four of potassium iodide in a pint of water. His *rubefacient iodine solution* is formed by dissolving half an ounce of iodine and an ounce of potassium iodide in six fluidounces of water. *Lugol's caustic iodine solution* containing iodine and potassium iodide, each, an ounce, dissolved in two fluidounces of water, was used to destroy soft and fungous granulations, and in *lupus.* To-day the aqueous solution is comparatively rarely employed externally. The official solution is used chiefly internally as a means of obtaining the therapeutic effects of iodine. It is also an efficient chemical antidote to most of the alkaloidal poisons.

Dose, of the U. S. P. solution, from two to five minims (0.12–0.3 cc.), three times a day, given in at least four tablespoonfuls of water or of milk, so as to avoid irritation of the stomach.

Off. Prep.—Liquor Iodi Phenolatus, *N. F.*

LIQUOR MAGNESII BICARBONATIS. Br.

SOLUTION OF MAGNESIUM BICARBONATE [Fluid Magnesia]

Liquor Magnesii Carbonatis, *Br.* 1898; Eau magnésienne, Magnésie liquide, *Fr.;* Kohlensaure Magnesialösung, Magnesiawasser, *G.*

"Magnesium Sulphate, 40 *grammes;* Sodium Carbonate, 50 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the two salts separately, each in two hundred *millilitres* of the Distilled Water; heat the solution of Magnesium Sulphate to the boiling point; add to it the solution of Sodium Carbonate; boil until carbon dioxide ceases to be evolved; collect the precipitate on a calico filter; wash it with Distilled Water until the filtrate is free from sulphates. Mix the washed precipitate with four hundred *millilitres* of Distilled Water; place the mixture in a suitable apparatus; force into it pure washed carbon dioxide; let the mixture remain in contact with excess of carbon dioxide, retained under a pressure of about three atmospheres, for twenty-four hours or longer; decant the resulting solution, and again pass carbon dioxide into it. Keep the Solution in securely closed bottles." *Br.*

The title of this solution was changed in the British Pharm., 1914, to "Solution of Magnesium *Bicarbonate.*" It was formerly solution of Magnesium *Carbonate;* the word bicarbonate more accurately describes the magnesium salt in the finished preparation.

The object of this process is to obtain a solution of magnesium bicarbonate by means of carbon dioxide, the carbonate being insoluble in pure water. The first step is to prepare a freshly precipitated hydrated magnesium carbonate, which is more readily dissolved than is a carbonate which has been kept for some time. As the magnesium carbonate of the Br. Pharmacopœia consists of three molecules of the neutral carbonate and one of magnesium hydroxide with four molecules of water, it follows that, in its preparation from the two salts used in the process, a portion of carbon dioxide escapes, and the boiling is directed to be continued until the escape of the gas ceases, so that the normal composition may be insured, and a longer heat, which might affect the constitution of the carbonate so as to diminish its solubility, avoided. The precipitate is thoroughly washed, in order to remove every trace of sodium sulphate, which may be indicated by the non-action of the test of barium chloride. The next step is to dissolve the precipitated carbonate in water impregnated with carbon dioxide, and, as the solution even thus favored is slowly effected, the carbonate is directed to remain exposed to the action of carbon dioxide, under pressure, for twenty-four hours, and still the whole of the carbonate is not dissolved, and filtration is necessary. According to the Br. Pharm., the solution "effervesces slightly, or not at all, when the containing vessel is first opened. Yields no characteristic *reactions* for sulphates. *Lead limit* 0.5 part per million. *Arsenic limit* 0.2 part per million. 20 millilitres evaporated to dryness yield a white residue, which after calcination weighs not less than 0.16 and not more than 0.19 gramme. This residue is insoluble in *water,* and when dissolved in a dilute acid yields the *reactions* characteristic of magnesium. This Solution contains the equivalent of about 2 grammes of the official Magnesium Carbonate in 100 millilitres; 1 fluid ounce contains the equivalent of about 10 grains." *Br.*

On exposure to the air, some of the carbon dioxide escapes, and a portion of the salt is deposited. According to Muncy, the preparation as it occurs in commerce is usually much below the standard strength.

This solution is but slightly effervescent, is clear, and should be free from bitterness. Nevertheless, its taste is more disagreeable than is that of the undissolved carbonate or hydroxide, over which it has no advantage. (See *Magma Magnesiæ.*)

Dose, as an antacid laxative, from one to two fluidounces (30–60 cc.).

LIQUOR MAGNESII CITRATIS. U. S.

SOLUTION OF MAGNESIUM CITRATE Liq. Mag. Cit.

"Solution of Magnesium Citrate contains, in each 100 cc., magnesium citrate corresponding to not less than 1.5 Gm. of MgO." *U. S.*

Liquor Magnesii Citrici; Solution of Citrate of Magnesium; Limonada Magnesii Citrici; Potio Magnesii Citrici; Limonade purgative au Citrate de Magnésie, *Fr.;* Flüssige Citronensaure Magnesia, Magnesiumcitratlösung, Magnesiumlimonade, *G.;* Limonata magnesiaca, *It.;* Limonada purgante de citrato magnesico, *Sp.*

"Magnesium Carbonate, 15.0 Gm.; Citric Acid, 35.0 Gm.; Syrup, 60.0 cc.; Purified Talc, 5.0 Gm.; Oil of Lemon, 0.1 cc.; Potassium Bicarbonate, 2.5 Gm.; Distilled Water, a sufficient quantity, to make 350 cc. Dissolve the citric acid in 150 cc. of hot distilled water in a suitable dish, and, having added the magnesium carbonate previously mixed with 100 cc. of distilled water, stir until it is dissolved. Then add the syrup, heat the mixed liquids to the boiling point, immediately introduce the oil of lemon, previously triturated with the purified talc, and filter the mixture, while hot, into a strong bottle (previously rinsed with boiling water) of suitable capacity. Add enough boiled distilled water to make the product measure 350 cc. Stopper the bottle with purified cotton, allow to cool, drop in the potassium bicarbonate, and immediately stopper the bottle securely. Lastly, shake the solution occasionally until the potassium bicarbonate is dissolved. Keep the bottle on its side in a cool place, preferably in a refrigerator. NOTE.—In this process the 2.5 Gm. of potassium bicarbonate may be replaced by 2.1 Gm. of sodium bicarbonate, preferably in tablet form." *U. S.*

This formula first appeared in the second edition of the U. S. Pharmacopœia of 1850. The original formula was soon found to have defects. The chief objection to the formula as originally framed was that the magnesium citrate, when the solution was kept for some days, crystallized out in the form of a white granular precipitate, which rendered the solution unfit for medicinal use. This precipitate was found by Procter to be $Mg_3(C_6H_5O_7)_2 + 14H_2O$. This still occurs to some extent, although more slowly, and probably cannot be avoided except by a very great reduction in the amount of magnesia. The U. S. P. (8th Rev.) process improved the formula by increasing the quantity of citric acid, using 33 Gm. instead of 30 Gm. formerly used. The use of potassium bicarbonate introduces potassium citrate, but in too small a proportion to be of any consequence.

Special bottles which have a "patent stopper" attached are very convenient, but they have been practically superseded by the crown stopper in many localities. Solid magnesium citrate is best used in the form of the effervescent magnesium citrate of the U. S. P., 1890. (See *U. S. D.*, 19th edition, p. 726.)

The formula of the U. S. evidently intends a partial sterilization by such recommendations as: boiling the mixed liquids, rinsing the bottle with boiling water, using boiled water for diluting the mixed liquids, and stoppering the bottle with purified cotton. These measures are helpful in destroying bacteria, but after all has been done the potassium bicarbonate or sodium bicarbonate added at the last may introduce germs which may develop growths. The oil of lemon should be fresh and without terebinthinate odor. The tincture made from fresh lemon peel would probably prove more satisfactory as a flavor.

Description and Physical Properties.—"A slightly yellow, clear, effervescent liquid, having a sweet, acidulous taste and a lemon flavor.

"Add 1 cc. of glacial acetic acid and 3 cc. of an aqueous solution of potassium acetate (1 in 2) to 10 cc. of Solution of Magnesium Citrate, shake the mixture vigorously, then gently rub the sides of the test tube with a glass rod for a few minutes, and allow to stand for one hour; no white crystalline precipitate soluble in ammonia T.S. is produced (*tartaric acid*). Dilute 2 cc. of the Solution with 8 cc. of distilled water, and add 5 drops of hydrochloric acid and 1 cc. of barium chloride T.S.; no turbidity is produced within one minute (*sulphate*). Dilute 2 cc. of the Solution with distilled water to 45 cc., add 5 cc. of ammonium oxalate T.S., and mix well; the resulting turbidity, if any, is not greater than the turbidity in a control test made with 1 cc. of a solution prepared as follows: Dissolve 1 Gm. of calcium carbonate, previously dried to constant weight at 200° C., in 1 cc. of acetic acid and 5 cc. of distilled water. Boil for about one minute, and dilute with distilled water to 100 cc. (*calcium*). Boil down exactly 10 cc. of the Solution to about 5 cc. to expel carbon dioxide, dilute with 15 cc. of distilled water, and titrate with half-normal sodium hydroxide, using phenolphthalein T.S. as indicator; it requires not less than 9.5 cc. of the alkali for neutralization (*minimum of acidity*). Concentrate the liquid, and transfer it completely with the aid of a little distilled water to a platinum or porcelain crucible, evaporate to dryness, and proceed as directed under the assay for alkali salts of organic acids, page 431; not less than 28 cc. of half-normal sulphuric acid should be consumed (*minimum of total citric acid*).

"**Assay for Magnesium Oxide.**—Measure exactly 10 cc. of Solution of Magnesium Citrate, transfer to a platinum or porcelain dish, evaporate to dryness, and ignite until most of the carbonaceous matter has burned off. Add to the residue 20 cc. of diluted hydrochloric acid, heat on a water bath for fifteen minutes, filter if necessary, and wash the residue thoroughly with hot distilled water. To the combined filtrate and washings, which should measure about 100 cc., add an excess of sodium phosphate T.S. (about 20 cc.), then gradually add ammonia T.S. with constant stirring until slightly alkaline. After ten minutes add 30 cc. of ammonia T.S., and allow the mixture to stand for twelve hours. Then filter, and wash the precipitate with a mixture of 1 volume of ammonia T.S. and 19 volumes of distilled water until free from chloride. Dry, and ignite to constant weight. The weight of the magnesium pyrophosphate ($Mg_2P_2O_7$) so obtained is not less than 0.414 Gm., indicating an equivalent of not less than 1.5 Gm. of MgO in 100 cc. of the Solution." *U. S.*

Overlooking the excess of acid which it contains, the salt present is the tribasic citrate, in which the six atoms of hydrogen from two molecules of citric acid are replaced by three atoms of magnesium. Accordingly, it consists of two molecules of citric acid and three atoms of magnesium. It is advisable in preparing the solution to introduce the magnesia in small portions, for if too hastily added it is liable to cause the formation of the neutral citrate, which cannot afterwards be readily dissolved. Dorvault made a solid magnesium citrate which is perfectly and readily soluble, by melting on a sand bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Magnesium citrate, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydroxide, but with eight or ten times its weight of water it forms a permanent solution. Simonin found that an insoluble magnesium citrate may be restored to solubility in boiling water by being thoroughly rubbed up with water so as to form a paste. The necessary trituration will be abridged if a little citric acid be added. For other modifications, suggestions, etc., see Kondratowisch, *N. R.*, 1883, p. 246; Neynaber, *A. J. P.*, 1884, p. 472 (the proposed substitution of acetic acid by the latter is not desirable, because of the impossibility of avoiding an empyreumatic taste); also A. B. Stevens, *Proc. Mich. State Pharm. Assoc.*, 1885; and F. W. Sennewald, *Nat. Drug.*, 1887.

Magnesium metatartrate has been proposed, in the place of the citrate, by Léger, who, however, states that as a purgative it is more powerful than the citrate, resembling the sulphate. On account of its pleasant taste it might, perhaps, be substituted for Epsom salt.

Uses.—This solution is a cooling cathartic, and operates mildly. It has come into extensive use in the United States, on account of the facility with which it may be taken and its acceptability to the stomach.

Dose, as a purge, the whole quantity directed in the formula, or twelve fluidounces (360 cc.); as a laxative, half that quantity.

LIQUOR MORPHINÆ ACETATIS. Br.

SOLUTION OF MORPHINE ACETATE

Soluté d'Acétate de Morphine, *Fr.;* Essigsaure Morphinlösung, *G.*

"Morphine Acetate, 1 *gramme;* Diluted Acetic Acid, 2 *millilitres;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Acetic Acid; dissolve the Morphine Acetate in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Morphine Acetate in 100 millilitres; 110 minims contain 1 grain." *Br.*

Morphine acetate often contains a little uncombined morphine, in consequence of the escape of a portion of the acid during its evaporation, and especially when this is pushed to dryness. It is on this account apt to be unreliable. Hence the addition of the diluted acetic acid, which at the same time neutralizes the alkaloid in excess and enables the solution to be completely effected. The alcohol is added as a preservative. The present solution contains about 1 per cent. of morphine acetate and is, therefore, about equivalent in strength to tincture of opium.

Dose, from ten to thirty minims (0.6–1.8 cc.).

LIQUOR MORPHINÆ HYDROCHLORIDI. Br.

SOLUTION OF MORPHINE HYDROCHLORIDE

Solution of Hydrochlorate of Morphine, *Br.* 1885; Liquor Morphinæ Muriatis, *Dub.;* Solution of Muriate of Morphia; Soluté de Hydrochlorate de Morphine, *Fr.;* Salzsaure Morphinlösung, *G.*

"Morphine Hydrochloride, 1 *gramme;* Diluted Hydrochloric Acid, 2 *millilitres;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Hydrochloric Acid; dissolve the Morphine Hydrochloride in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Morphine Hydrochloride in 100 millilitres; 110 minims contain 1 grain." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the acid probably to assist in the solution of the salt. The solution contains about 1 per cent. of morphine hydrochloride.

Dose, from ten to thirty minims (0.6–1.8 cc.).

LIQUOR MORPHINÆ TARTRATIS. Br.

SOLUTION OF MORPHINE TARTRATE

Soluté de Tartrate de Morphine, *Fr.;* Weinsteinsaure Morphinlösung, *G.*

"Morphine Tartrate, 1 *gramme;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water; Dissolve the Morphine Tartrate in the mixture; add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Morphine Tartrate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This solution was introduced into the Br. Ph., 1898, because of the superior solubility and stability of the morphine tartrate, alcohol being used to preserve the liquid. It is of the same strength as the other solutions of morphine, about 1 per cent. It is not intended for hypodermic use and should not be confounded with the *Injectio Morphinæ Hypodermatica. Magendie's Solution of Morphine* was of the strength of 16 grains to the fluidounce.

Dose, from ten to thirty minims (0.6–1.8 cc.).

LIQUOR PANCREATIS. Br.

PANCREATIC SOLUTION

"Pancreatic Solution contains the digestive principles of the fresh pancreas of the pig." *Br.*

Liquor Pancreatius; Soluté de Pancreátine, *Fr.;* Pancreatinlösung, Pankreasessenz, *G.*

"Mix two hundred and fifty *millilitres* of Alcohol (90 per cent.) with two hundred *millilitres* of Glycerin and sufficient Distilled Water to produce one thousand *millilitres.* In this mixture macerate for seven days two hundred and fifty *grammes* of the pancreas, freed from fat and external membrane, and finely divided by trituration with washed sand or powdered pumice stone; filter." *Br.*

This official preparation of the Br. Ph., 1898, has been introduced to supply the demand for a liquid digestive solution made from the pancreas; it closely resembles the preparation recommended by Benger. (*Proc. Roy. Soc.*, xxxii, 145; see also *Pancreatinum.*) "When 3 *millilitres* of the Solution together with 0.2

gramme of *sodium bicarbonate* and 20 *millilitres* of *water* are added to 80 *millilitres* of milk and the mixture kept at 45° C. for one hour, on placing 5 millilitres of this liquid with 5 *millilitres* of *ether* and 5 drops of *nitric acid* in a stoppered tube and gently inverting the tube three times, no curdy precipitate appears in the lower layer." *Br.*

The solution digests albuminoids, converts starch into sugar in an alkaline solution, albumin and fibrin into peptones, and peptonizes milk. As it acts normally in alkaline solutions, while the gastric juices are strongly acid, its practical value as an internal medicament is doubtful. Its chief value is for the predigestion of foods.

Dose, from one to two fluidrachms (3.75–7.5 cc.).

LIQUOR PICIS CARBONIS. Br.

SOLUTION OF COAL TAR

Soluté de Goudron de Houille, *Fr.;* Kohlenteerlösung, *G.*

"Prepared Coal Tar, 200 *grammes;* Quillaia Bark, in No. 20 powder, 100 *grammes;* Alcohol (90 per cent.), 1000 *millilitres.* Exhaust the powdered Quillaia Bark with the Alcohol by the *percolation process.* To the resulting tincture add the Prepared Coal Tar, and digest the mixture at 50° C. for two days, stirring occasionally. Cool and decant, or filter." *Br.*

This solution of the Br. Ph., 1898, is practically identical with *Liquor Carbonis Detergens, Coal Tar Saponin,* and the *Liquor Picis Carbonis* of the N. F. (see Part III), and similar well-known preparations which have been largely used by dermatologists. The process for solution of coal tar is modelled after that for *compound tincture of coal tar,* proposed by L. A. Duhring. It owes its virtues largely to phenol and other derivatives of coal tar. (See *Pix Carbonis Præparata.*)

Solution of coal tar is stimulating, and is prescribed, diluted with from ten to fifty parts of water, as a wash in *eczema, psoriasis, pruritus,* and other skin diseases.

LIQUOR PITUITARII. U. S.

SOLUTION OF PITUITARY Liq. Pituitar.

[Liquor Hypophysis, U. S. P. IX, Pituitary Extract]

"Solution of Pituitary contains the water-soluble principle or principles from the fresh posterior lobe of the pituitary body of cattle, 1 cc. having an activity upon the isolated uterus of the virgin guinea-pig, corresponding to not less than 80 per cent. and not more than 120 per cent. of that produced by 0.005 Gm. of the Standard Powdered Pituitary, prepared as directed below. The solution should be sterile." *U. S.*

This solution was introduced into the U. S. P. IX because of the great difference in the potency of the commercial preparations on the market. The hope that an official standard would lead to a unification in the output of various manufacturers has, however, not been realized, perhaps because the official solution was much weaker than most of those put out by various manufacturing houses under trade names. The present Pharmacopœia has continued the solution modifying, however, the standard of strength.

Because of the impracticability for the ordinary retail pharmacists to manufacture solutions of the pituitary body, the Pharmacopœia does not give any process.

"**Description and Physical Properties.**—A transparent liquid, colorless, or nearly so, having a faint, characteristic odor." *U. S.*

Assay.—In our complete ignorance of the active principle of the pituitary, the only possible means of standardizing this preparation is by a physiological test. Although several methods for the bio-assay have been suggested the only one which has found any general favor is that based on the increase in the contractions of the isolated uterus caused by the drug as compared to the action of a substance of known activity. Formerly the U. S. P. recognized as the standard for comparison beta-iminazolylethylamine, but experience having shown that it is practicably impossible to obtain this of uniform quality the present revision employs a standard preparation of pituitary which is made as follows:

Standard Powdered Pituitary.—"Select a number, not less than 25, of fresh posterior lobes of the pituitary body of cattle, removed within thirty minutes of the death of the animal and carefully free them from all extraneous tissue, immediately after their removal. As soon as they are so prepared, drop them into a flask containing a quantity of acetone corresponding to not less than 4 cc. of acetone for each pituitary body. Allow them to remain in the acetone for three hours, and then remove them and immediately cut them into small pieces with scissors and place the material in fresh acetone equal in quantity to that first employed. Leave the material in the acetone over night, and then remove it and dry it in a vacuum desiccator over calcium chloride, at a temperature not above 50° C., for five hours. At the end of this time remove the material and grind it in a mortar until it will pass through a No. 40 sieve. Dry this powder for at least twelve hours in a vacuum desiccator over calcium chloride at a temperature not over 50° C. Extract this dried powder in a small Soxhlet continuous extraction apparatus with acetone for three hours and again dry it in a desiccator over calcium chloride for twelve hours. This dried powder should be preserved in a cool, dark place, in sealed ampuls *in vacuo,* or in vacuum desiccators over calcium chloride until used for the preparation of the standard solution." *U. S.*

"Prepare a solution as follows: Carefully weigh a suitable amount of the dried Standard Powdered Pituitary, place this weighed powder in a small agate mortar and moisten with a few drops of distilled water containing 0.25 per cent. of acetic acid. Triturate the moistened powder thoroughly until the whole is of an impalpable frothy consistence. Add a few cc. of the 0.25 per cent. acetic acid solution and stir the mixture thoroughly. Transfer to a hard glass test tube or beaker; rinse the small agate mortar with the acetic acid solution and add the rinsings to the pituitary mixture; then add enough 0.25 per cent. acetic acid to make the final volume of the mixture of the same number of cc. as the number of milligrams of dried pituitary powder originally taken. Heat this mixture to the boiling point for not more than one minute and filter. The filtrate contains in each cc. the active principle of 0.001 Gm. of the dried standard powder. Place this solution in hard glass ampuls and sterilize by fractional sterilization for twenty minutes on three successive days at a temperature not exceeding 100° C. Preserve in a cool place (from 5° to 20° C.). This standard solution should not be kept more than six months.

"The apparatus used for making the test may be any modification of the general type for studying the activity of the isolated smooth muscle of mammals. It must be provided with an accurate temperature-regulating device. The chamber in which the uterus is suspended should have a capacity of not less than 100 cc. Use healthy guinea pigs weighing between 175 Gm. and 350 Gm. They should not have been pregnant and should not be in heat. It is recommended that young female pigs be segregated at the time of weaning and kept thereafter out of sight and smell of the males.

"Kill a guinea pig by a blow on the head, or by decapitation and immediately remove the entire uterus from the body. Suspend a part or all of one horn of the uterus in a chamber containing oxygenated Locke-Ringer solution (page 489), one end of the uterus being attached to a muscle lever which is weighted as necessary. The temperature of the bath should be between 37° and 38° C. but should not vary more than one-tenth of a degree throughout the whole assay. When the uterus is completely relaxed, which is generally in from fifteen to thirty minutes, it is ready to begin the test. This is done by adding alternately varying doses of the standard extract and of the solution to be tested to the bath in the muscle chamber until quantities of the two solutions are found which give equal, sub-maximal contractions in at least two successive pairs of contractions. The strengths of the two solutions are in inverse ratio to the quantities necessary to produce these equal contractions." *U. S.*

The uterine assay method requires such complex apparatus and presents so many technical difficulties that the results are reliable only when carried out in especially equipped laboratories by thoroughly experienced observers. A brief description of the general principles of the method may, however, not be out of place. The test is performed by adding a carefully measured quantity of the solution to a bath containing the uterus suspended in a warm physiological solution (see *Locke-Ringer Solution,* Part III), one end of the uterus being attached to a fixed point and the other end to a light lever which records the movements of the muscle upon a smoked surface. The usual feeble, spontaneous, contractions of the uterus can be overcome by weighting the lever so as to put a certain amount of tension on the muscle. In carrying out the test a carefully measured quantity of the standard solution is injected into the bath (the amount of which will vary with the amount of fluid in the bath as well as the susceptibility of the individual muscle) and records made of the resultant contraction. After these have reached their maximum the fluid is withdrawn from the bath and the bath filled with fresh, previously warmed Locke solution in order to wash out any traces of the drug. This is in turn again withdrawn and the bath filled with fresh solution into which is injected a quantity of the solution to be tested and the contractions recorded as before. This process, of repeated injections of the pituitary into the bath and its withdrawal, is continued with varying doses alternately of the standard preparation and of the one being tested until contractions of equal size are produced by the two solutions.

The following are some of the more obvious technical details which must be observed: The temperature of the bath in which the uterus is suspended must be constantly the same throughout the whole course of the experiment. This is usually accomplished by inserting the container in a large tank of warm physiological salt solution whose temperature is kept constant by means of some heating mechanism either electrical or a Bunsen burner.

The fresh Locke solution which is added between each test must be of the same temperature as the bath in which the uterus is suspended. This can be most conveniently accomplished by keeping the containers of the Locke solution in the same large tank in which the uterine bath is kept.

Arrangements must be made for constant fresh supply of oxygen in the uterine bath. This is generally done by having a tube, connected with an oxygen tank, pass into the bath and a small quantity of oxygen allowed to bubble up continuously through the fluid.

The weight upon the lever must be sufficient to completely relax the uterus but not too heavy for the muscle to lift.

The delicacy of the reactions and the necessity for absolute similarity of conditions may be suggested by noting some of the sources of error which have been reported: variations in the quality of sodium chloride, even when using the purest salt obtainable (see Pittenger and Quici, *J. A. Ph. A.*, 1923, xii, 14); changes in the hydrogen ion concentration of the Locke solution due either to original impurities in the glucose or to alterations occurring on standing; changes in the quality of oxygen bubbling up through the bathing solutions.

Hamilton (*J. A. Ph. A.*, 1919, viii, 58) prefers a blood-pressure test. The technique for this is the same as for that described under *Liquor Epinephrinæ*, except that the intervals between injections must be longer; the comparison of activity may be made with a standard pituitary solution prepared according to the official method.

Smith and McClosky (*U. S. Hygienic Lab.*, 1924, Bull. 138) find that pituitary solutions carefully prepared and sterilized do not depreciate in activity at least for one year if kept in a low temperature. In warm places deterioration takes place more or less rapidly in proportion to the degree of warmth; at a temperature of 37° C. the solutions retain their activity practically unimpaired for two months, but at 60° C. there is almost complete destruction of the active principles within three months. Similar conclusions were reached by Tate (*P. J.*, 1921, cvi, 268).

Uses.—The solution of the posterior lobe of the pituitary body possesses the physiological action and therapeutic properties of this organ, but has the great advantage of being in a convenient form for administration, especially for hypodermic use. While it is probable that even when given by the mouth the pituitary exerts an effect upon the functions of the body, it is certainly more active when administered hypodermically and is to-day rarely exhibited orally. As it is impracticable for the retail pharmacist to prepare sterile solutions of the hypophysis of definite activity, the apothecary will ordinarily stock one of the commercial solutions. These preparations—which are sold under various trade names as *pituitrin, pituitol, pituglandol, hypophysin, pituitary extract*, etc.—vary, however, greatly in their activity. According to Pittenger (*J. A. Ph. A.*, 1917, vi), the commercial solutions of hypophysis are from two to five times as strong as the standard given in the U. S. P.; a fact which it is important that both the physician and the druggist realize, as overdoses of this remedy are capable of much harm. It is to be hoped that with the present practicable standards manufacturers will make their products to conform to the official requirements. The most frequent use of this drug is as a uterine stimulant, especially in *labor*, although it is sometimes used as a circulatory stimulant in surgical *shock*. (See under *Pituitarium.*) It is also used as an intestinal stimulant, especially in post-operative tympanitis.

Dose, of the U. S. P. preparation, ten to twenty minims (0.6–1.2 cc.).

LIQUOR PLUMBI SUBACETATIS.
U. S. (Br.)
SOLUTION OF LEAD SUBACETATE Liq. Plumb. Subacet [Goulard's Extract]

"An aqueous solution containing lead subacetate, approximately $Pb_2O(CH_3.COO)_2$, corresponding to not less than 18 per cent. of Pb." *U. S.*

Liquor Plumbi Subacetatis Fortis, *Br.;* Strong Solution of Lead Subacetate; Acetum Plumbi, Acetum Saturni, Plumbum Hydrico-Aceticum Solutum; Acétate (sous-) de Plombliquide, Extrait de Goulard, Vinaigre de Plomb (de Saturne), *Fr.;* Liquor Plumbi Subacetici, *P. G.;* Bleiessig, *G.*

"Lead Acetate, 220 Gm.; Lead Monoxide, 140 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Triturate the lead monoxide to a smooth paste with 100 cc. of distilled water, and transfer the mixture to a bottle of about 1000 cc. capacity, using an additional 100 cc. of distilled water for rinsing. Dissolve the lead acetate in 700 cc. of distilled water, and add the solution to the lead oxide mixture. Shake vigorously for five minutes, then set it aside for seven days, shaking frequently during this time. Finally filter, protecting the solution from undue contact with the air, and pass enough distilled water through the filter to make the product measure 1000 cc. This solution may also be prepared as follows: Boil the mixture of lead acetate, lead monoxide, and water for half an hour in a suitable flask, adding small portions of distilled water as necessary to maintain the volume. Then cool, and filter. The funnel during filtration should be covered to protect the solution from the action of air, and enough boiled distilled water passed through the filter to make the product measure 1000 cc." *U. S.*

"Lead Acetate, 250 *grammes;* Lead Oxide, in powder, 175 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres*. Dissolve the Lead Acetate in seven hundred and fifty *millilitres* of the Distilled Water, add the Lead Oxide, set aside for forty-eight hours, shaking occasionally; filter, and pass through the filter sufficient Distilled Water to produce the required volume." *Br.*

The Br. Pharm., 1914, adopted a "cold process" for making this solution and inserts an assay process as a test. This is necessary to secure uniformity and establish a standard.

The U. S. P. X process does not differ essentially from that formerly official. Several methods have been proposed for making this by a process which will eliminate the necessity of boiling. For Haussmann's method by agitating the lead salts with hot water and subsequently adding the lead oxide and occasionally agitating until cold, see *A. J. P.*, 1897, 559; *M. R.*, 1896, 329; *Ph. Rev.*, 1896, 250.

In many pharmaceutical manufacturing laboratories when this preparation is made on the large scale, the cold process is always used as it seems to work very well with large quantities, and the final adjustment is then made to the standard strength after assaying the preparation.

Description and Physical Properties.—"A clear, colorless, odorless liquid, having a very sweet, astringent taste. It is alkaline to litmus paper but not to phenolphthalein T.S. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate.

" Specific gravity: about 1.25 at 25° C. When 1 cc. of Solution of Lead Subacetate is added to 5 cc. of mucilage of acacia (1 in 10), it produces a dense white precipitate (*distinction from normal lead acetate*). Solution of Lead Subacetate responds to the reactions for lead, and for acetates. Solution of Lead Subacetate yields with potassium ferrocyanide T.S. a white precipitate, tinged with neither red nor blue (*copper or iron*).

"**Assay.**—Place about 1 cc. of Solution of Lead Subacetate, accurately weighed, in a 200 cc. volumetric flask, dilute with 50 cc. of recently boiled distilled water, and add 50 cc. of tenth-normal oxalic acid. Agitate the mixture thoroughly for five minutes, fill to the mark with distilled water, shake, and filter, rejecting the first 20 cc. of the filtrate. Add 5 cc. of sulphuric acid to 100 cc. of the filtrate, warm to about 70° C., and titrate the residual oxalic acid with tenth-normal potassium permanganate. Each cc. of tenth-normal oxalic acid corresponds to 0.01036 Gm. of Pb.

" Preserve in well-stoppered bottles." *U. S.*

"A clear colorless liquid, with a sweet astringent taste; alkaline to *litmus.* Becomes turbid by exposure to the air. Forms an opaque white jelly with *mucilage of gum acacia.* Yields the *reactions* characteristic of lead and of acetates. Specific gravity 1.275. When 1 gramme is diluted with 20 millilitres of *water* and mixed with excess of *N/1 solution of oxalic acid,* the precipitate collected, washed, transferred to a flask and decomposed with excess of *diluted sulphuric acid,* the mixture thus obtained heated to 60° C., decolorises not less than 17 millilitres of *N/10 solution of potassium permanganate." Br.*

When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Barker, are flat, rhomboidal prisms, with dihedral summits. Jeannel prepares *crystallized lead subacetate* in accordance with the following formula: Triturate six parts of neutral lead acetate with two parts of pure litharge, and add one part of water. Heat in a porcelain dish, stirring with a glass rod, until fusion and finally ebullition occur. After two or three minutes of boiling, filter through paper in a funnel heated by a sand bath. Allow to cool and crystallize. (*J. P. C.*, 4e sér., xi, 54.)

Incompatibilities.—One of its most striking properties is the extreme facility with which it is decomposed. Carbon dioxide throws down a white precipitate of lead carbonate; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has not been recently boiled. Solutions of gum, tannin, most vegetable coloring principles, and many animal substances, particularly albumin, produce with it precipitates consisting of the substance added and lead oxide. It should be kept in well-stoppered bottles. It is distinguished from the solution of lead acetate by being precipitated by gum arabic.

Owing to the liability to serious results due to the frequent confounding of the name lime water and lead water, it is safer to dispense lead water in a slightly opalescent condition, while lime water should be perfectly transparent.

Uses.—This solution is astringent and sedative but is employed only as an external application. It is widely used, especially mixed with an equal part of tincture of opium—a mixture commonly known as *lead water and laudanum*—in inflammation arising from *sprains, bruises, burns, blisters,* etc., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. Blackburn (*J. A. M. A.*, 1906, xlvi, p. 954) reports erythema following the local application of lead water and laudanum, and we have seen blistering apparently resulting from this popular embrocation. From four fluidrachms to a fluidounce (15–30 cc.), added to a pint (480 cc.) of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; and poisoning by its injection for *gonorrhea* has been reported. (*Dublin Journ. Med. Sci.*, 1874.) The common name of Goulard's extract is derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.

Off. Prep.—Liquor Plumbi Subacetatis Dilutus, *N. F., Br.;* Ceratum Plumbi Subacetatis, *N. F.;* Glycerinum Plumbi Subacetatis, *Br.;* Unguentum Plumbi Subacetatis, *Br.*

LIQUOR PLUMBI SUBACETATIS DILUTUS. Br.

DILUTED SOLUTION OF LEAD SUBACETATE

Aqua Saturnina; Goulard's Lotion, Goulard's Water, Lead Water; Diluted Solution of Subacetate of Lead; Lotion à l'Acétate de Plomb, Eau de Saturne, Eau de Goulard, Eau blanche, *Fr.;* Aqua Plumbi, *P. G.;* Bleiwasser, Kuhlwasser, *G.*

" Strong Solution of Lead Subacetate, 12.5 *millilitres;* Distilled Water, recently boiled and cooled, sufficient to produce 1000.0 *millilitres.* Mix." *Br.*

The direction to dilute the strong solution with distilled water *previously boiled and cooled* is an improvement, as even the small amount of carbon dioxide dissolved in distilled water usually made the lead water cloudy.

This preparation is too weak to be of any real value. A similar solution is recognized by the N. F.

LIQUOR POTASSII ARSENITIS.
U. S. (Br.)

SOLUTION OF POTASSIUM ARSENITE Liq. Pot. Arsen. [Fowler's Solution Liquor arsenicalis Fowleri P I.]

" Solution of Potassium Arsenite contains, in each 100 cc., potassium arsenite ($KAsO_2$), equivalent to not less than 0.975 Gm. and not more than 1.025 Gm. of As_2O_3." *U. S.*

Liquor Arsenicalis, *Br.;* Arsenical Solution; Solutio Arsenicalis Fowleri, Kali Arsenicosum Solutum; Liquor Fowleri; Aqua Arsenitis Potassici; Solutio Kalii Arsenicosi, *Fr. Cod.;* Soluté d'Arsenite de Potasse, Liqueur de Fowler, Liqueur arsénicale de Fowler, *Fr.;* Liquor Kalii arsenicosi, *P. G.;* Fowlersche Lösung, *G.;* Soluzione alcalina di arsenito de potassio, Liquore del Fowler, *It.;* Solucion de arsenito potasico, Licor arsenical de Fowler, *Sp.*

"Arsenic Trioxide, 10 Gm.; Potassium Bicarbonate, 20 Gm.; Compound Tincture of Lavender, 30 cc.; Distilled Water, a sufficient quantity to make 1000 cc. Boil the potassium bicarbonate and arsenic trioxide in a flask with 100 cc. of distilled water until solution is effected. Cool the solution, and transfer it to a 1000 cc. graduated container, rinsing the flask in which the liquid was boiled with several portions of distilled water to make a solution measuring 970 cc. Add the compound tincture of lavender, mix thoroughly, and filter if necessary." *U. S.*

"Arsenious Anhydride, in powder, 10 *grammes;* Potassium Carbonate, 10 *grammes;* Compound Tincture of Lavender, 30 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve the Arsenious Anhydride and the Potassium Carbonate in five hundred *millilitres* of Distilled Water by the aid of heat; cool; add the Compound Tincture of Lavender and sufficient Distilled Water to produce the required volume." *Br.*

This preparation originated with Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy known under the name of "the *tasteless ague drop.*" It now contains potassium arsenite corresponding in amount to 1 per cent. of arsenic trioxide, corresponding with the International Protocol. It is a potassium arsenite dissolved in water, and is formed by the combination of the arsenic trioxide with the potassium of the bicarbonate or carbonate, carbon dioxide being evolved. In the present U. S. process the bicarbonate has been preferred to the carbonate and in order to expedite the process the quantity has been doubled. As the bicarbonate is decomposed to carbonate by boiling water, there is present in the finished solution some potassium carbonate. According to M. H. Buignet, ebullition disengages the carbon dioxide slowly, so that after four hours' boiling the solution still retains about one-sixth of this gas. The name by which the preparation is designated in the U. S. Pharmacopœia is the more correct. The contact of arsenic trioxide with potassium bicarbonate in the presence of a small quantity of boiling water gives rise to effervescence with decomposition of bicarbonate. The compound tincture of lavender is added to give it taste and prevent its being mistaken for water. For Oldberg's process, see *Proc. A. Ph. A.*, 1893, 430; see also *A. J. P.*, 1895, 403.

Vanderkleed and E'we (*Proc. P. Ph. A.*, 1916, p. 283) point out that there are substances of widely differing composition offered in the market under the name of potassium arsenite. One of these consists of pure $KAsO_2$, while the other is $KAsO_2.H_3AsO_3$.

Description and Physical Properties.—"A clear or faintly opalescent liquid, having a pink color and a slight odor of lavender. It is alkaline to litmus paper.

"Add to 10 cc. of the Solution an excess of hydrochloric acid and an equal volume of hydrogen sulphide T.S.: a yellow precipitate is produced which is soluble in ammonium carbonate T.S.

"Acidulate 4 cc. of Solution of Potassium Arsenite with diluted nitric acid, add 1 cc. of silver nitrate T.S., and superimpose a layer of ammonia T.S. upon this liquid: no red or reddish-brown color is observed at the line of contact (*arsenate*).

"**Assay.**—Measure exactly 20 cc. of Solution of Potassium Arsenite, dilute with 75 cc. of distilled water, acidify the mixture very slightly with diluted hydrochloric acid, then dissolve in the solution 2 Gm. of sodium bicarbonate, and titrate the resulting liquid with tenth-normal iodine, starch T.S. being used as indicator. Each cc. of tenth-normal iodine corresponds to 0.004948 Gm. of As_2O_3." *U. S.*

"A reddish liquid, alkaline to *litmus,* and having the odor of lavender, 25 millilitres, neutralised with *hydrochloric acid,* discharge the color of 50.4 millilitres of *N/10 solution of iodine,* the presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation. This Solution contains 1 gramme of Arsenious Anhydride in 100 millilitres; 110 minims contain 1 grain." *Br.*

According to R. Fresenius, solutions of alkaline arsenites slowly absorb oxygen from the air, and are in part converted into arsenates. Hence the propriety of keeping this solution in small bottles well filled. Mohr states that the alkaline reaction of the official solution delays the change, and experience has confirmed this statement. The slight precipitate found in this solution after keeping proved to be silicic acid, caused by the action of the alkaline solution on the glass container.

Uses.—This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arseni Trioxidum.* Its liquid form makes it convenient for exhibition and gradual increase, and it is the preparation generally resorted to when arsenic is given internally. It has been much employed in *intermittent fever, skin diseases,* and the other affections for which arsenic is employed. In *chorea* it is almost a specific, and in *nervous diseases* of debility it is often very useful. In *malarial affections* and *chorea* it should be administered in ascending doses until the puffiness about the eyes or disturbance of the bowels betrays the arsenical impression. For the peculiar effects upon the human organisms, see *Arseni Trioxidum.*

Dose, three to five minims (0.2–0.3 cc.), which may be gradually increased.

LIQUOR POTASSII CITRATIS. U. S.

SOLUTION OF POTASSIUM CITRATE Liq. Pot. Cit. [Neutral Mixture]

"Solution of Potassium Citrate contains, in each 100 cc., not less than 8 Gm. of $K_3C_6H_5O_7$, with small amounts of citric and carbonic acids. *Caution—This preparation must not be dispensed unless it has been recently prepared.*" *U. S.*

Mistura Potassii Citratis; Liquor Kalii Citrici; Citrate de Potasse liquide, *Fr.;* Flüssiges Citronensaures Kali, Kaliumcitratlösung, *G.*

"Potassium Bicarbonate, 8 Gm.; Citric Acid, 6 Gm.; Distilled Water, a sufficient quantity to make 100 cc. Dissolve the potassium bicarbonate and the citric acid, each, in 40 cc. of distilled water. Filter the solutions separately, and wash the filters with enough distilled water to obtain in each case 50 cc. Mix the two solutions, and when effervescence has ceased, transfer to a bottle and stopper tightly." *U. S.*

The official solution is stronger than the so-called mixture of citrate of potassium (or *neutral mixture*), which it superseded some years ago. The latter preparation was directed to be prepared from fresh lemon juice, and, while more palatable, was very irregular in its strength which was entirely dependent upon the citric acid content of the lemon juice. An improvement has been made in the present official solution in directing the acid and the alkaline salt to be dissolved separately, and the direction to dispense the preparation in a fresh condition will undoubtedly lead to the keeping of the filtered solutions, by the pharmacist, in separate bottles, and mixing in equal measures or weights when prescribed. The solutions keep well for a considerable length of time, and there is thus greater convenience and a saving of time and labor.

Description and Physical Properties.—"A clear, colorless, odorless liquid, slightly acid to litmus paper. It meets the requirements of the tests for identity and purity of an aqueous solution of potassium citrate under *Potassii Citras* when suitably concentrated.

"**Assay.**—Measure exactly 15 cc. of Solution of Potassium Citrate, evaporate to dryness, and proceed as directed under the Assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.05106 Gm. of $K_3C_6H_5O_7$." *U. S.*

Uses.—The solution of potassium citrate has long been used under the name of *neutral mixture, saline mixture,* or *effervescing draught.* It formerly was much used as a refrigerant diaphoretic, in cases of *fever* with dry skin, but has been largely superseded by the more potent antipyretics. It has the therapeutic virtues of potassium citrate and the presence of the carbonic acid often makes it more acceptable to the stomach.

Dose, of official solution, four fluidrachms (15 cc.).

LIQUOR POTASSII HYDROXIDI. U. S. (Br.)

SOLUTION OF POTASSIUM HYDROXIDE Liq. Pot. Hydrox. [Liquor Potassæ Pharm. 1890, Solution of Potassa]

"Solution of Potassium Hydroxide contains, in each 100 cc., not less than 4.5 Gm. and not more than 5.5 Gm. of KOH." *U. S.* "Solution of Potash is an aqueous solution containing in 100 millilitres 5 grammes of pure potassium hydroxide, KOH. It should be preserved in a green glass bottle furnished with an air-tight stopper." *Br.*

Liquor Potassæ, *Br.;* Kali Hydricum Solutum, Lixivium Causticum; Solution of Potash; Potasse caustique liquide, Lessive caustique, *Fr.;* Liquor Kali Caustici, *P. G.;* Aetzkalilauge, Kalilauge, *G.*

"Dekanormal Solution of Potassium Hydroxide, 90 cc.; Distilled Water, a sufficient quantity to make 1000 cc. Mix the dekanormal solution, with sufficient distilled water to make 1000 cc. NOTE.—The 90 cc. of dekanormal solution of potassium hydroxide may be replaced by 60 Gm. of potassium hydroxide, containing 85 per cent. of KOH." *U. S.*

For description of dekanormal solution of potassium hydroxide, see Part III.

The British Pharmacopœia, 1914, does not give a detailed process, merely specifying that one hundred millilitres shall contain five grammes of potassium hydroxide.

Description and Physical Properties.—"A clear, colorless, odorless liquid, strongly alkaline and caustic, readily absorbing carbon dioxide from the air. Specific gravity: about 1.046 at 25° C. It meets the requirements of the tests for identity and purity for an aqueous solution of potassium hydroxide under *Potassii Hydroxidum* when suitably concentrated. Measure exactly 20 cc. of Solution of Potassium Hydroxide into a suitable flask and titrate directly with normal hydrochloric acid, using methyl orange T.S. as indicator: it shows, in each 100 cc., not more than 5.5 Gm. of alkali, calculated as KOH (*carbonate*).

"**Assay.**—Measure exactly 50 cc. of Solution of Potassium Hydroxide into a 250 cc. measuring flask, add 20 cc. of barium chloride T.S., and fill the flask to the mark with recently boiled distilled water. Thoroughly agitate the liquid, filter it through a filter not previously moistened, reject the first 20 cc., and titrate 100 cc. of the filtrate, representing 20 cc. of the Solution, with normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.05611 Gm. of KOH.

"Preserve in bottles made of hard glass, and provided with rubber stoppers or with glass stoppers coated with petrolatum." *U. S.*

"A colorless, strongly alkaline liquid. Yields no characteristic *reactions* for lead, copper, arsenic, iron, aluminium, calcium, magnesium, sodium, or ammonium, and not more than the slightest *reactions* for carbonates, chlorides, or sulphates. Specific gravity 1.045. 20 millilitres require for neutralisation 17.8 millilitres of *N/1 solution of sulphuric acid.* This Solution contains 5 grammes of Potassium Hydroxide, KOH, in 100 millilitres; 110 minims contain 5 grains." *Br.*

It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feeling, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. It is incompatible with acids, acidulous salts, and all metallic and earthy salts held in solution by an acid; also with all ammonia salts, and with calomel and corrosive sublimate. The two official solutions of potassium hydroxide are now nearly identical in strength, the U. S. solution having the sp. gr. 1.046 at 25° C., and the Br. 1.045 at 15.5° C. On account of its strong attraction for carbon dioxide, solution of potassium hydroxide should be carefully preserved from contact with the air.

Uses.—Solution of potassium hydroxide is powerfully antacid, and mildly diuretic, and was formerly much used, but, on account of its irritant properties, has been superseded by the carbonated alkalies as an internal remedy.

Dose, ten to thirty minims (0.6–1.8 cc.).

LIQUOR POTASSII PERMANGANATIS. Br.

SOLUTION OF POTASSIUM PERMANGANATE

Soluté de Permanganate de Potasse, *Fr.;* Kaliumpermanganatlösung, *G.;*

" Potassium Permanganate, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Dissolve. This Solution contains 1 gramme of Potassium Permanganate in 100 millilitres; 110 minims contain 1 grain." *Br.*

This is an unstable 1 per cent. solution of potassium permanganate which decomposes upon exposure and deposits manganese oxides.

Dose, officially given in the Br., is from two to four fluidrachms (7.5–15 cc.), equivalent to from 1.1 to 2.2 grains of the salt, but very few stomachs will bear more than one grain (0.065 Gm.) of the permanganate.

LIQUOR SODÆ CHLORINATÆ.
U. S., Br.

SOLUTION OF CHLORINATED SODA Liq. Sod. Chlorinat. [Labarraque's Solution]

" An aqueous solution of chlorine compounds of sodium, containing not less than 2.5 per cent. of NaOCl, equivalent to not less than 2.5 per cent. of available chlorine." *U. S.*

Liquor Sodæ Chlorati, *U. S.* 1890; Liquor Natri Chlorati; Liquor Natri Hypochlorosi· Bleaching Solution; Chlorure de Soude liquide, *Fr. Cod.;* Liqueur de Labarraque, *Fr.;* Chlornatronlösung, Bleichflüssigkeit, *G.;* Solucion de hipoclorito sodico, Licor de Labarraque, *Sp.*

" Monohydrated Sodium Carbonate, 70 Gm.; Chlorinated Lime, 100 Gm.; Water, a sufficient quantity to make 1000 Gm. Triturate the chlorinated lime with 500 cc. of water gradually added until a uniform mixture results. Dissolve the monohydrated sodium carbonate in 500 cc. of warm water, and add this solution to the chlorinated lime mixture contained in a suitable vessel. Stir or shake the mixture thoroughly, and if it becomes gelatinous warm the vessel very gently until its contents again liquefy. Then transfer the mixture to a wetted muslin strainer, and return the first portion until the liquid passes through clear. Add a few drops of sodium carbonate T.S. to 10 cc. of this clear filtrate. If it remains clear on the addition of the reagent, continue the operation without further treatment. If the filtrate becomes cloudy, return the mixture to the vessel, add sufficient monohydrated sodium carbonate to precipitate the excess of lime and again filter, returning the first portions until the liquid passes through clear. When no more liquid drains from the filter, wash the precipitate with enough water to make the product weigh 1000 Gm." *U. S.*

" Chlorinated Lime, 100 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, 1000 *millilitres.* Dissolve the Sodium Carbonate in two hundred and fifty *millilitres* of the Distilled Water; thoroughly triturate the Chlorinated Lime with the remainder of the Distilled Water; mix the two liquids; shake occasionally during three or four hours; filter. This Solution should be freshly prepared." *Br.*

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It must not be confused with Dakin's solution (see *Liquor Sodæ Chlorinatis Surgicalis*). The U. S. process is practically that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of monohydrated sodium carbonate by one of chlorinated lime. Calcium carbonate is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of sodium carbonate, the presence of which renders the solution more permanent.

Description and Physical Properties.—"A clear, pale greenish liquid, having a faint odor suggesting chlorine, and a disagreeable, alkaline taste. The Solution at first colors red litmus paper blue and then bleaches it. The addition of hydrochloric acid to the Solution causes an evolution of chlorine and carbon dioxide.

"**Assay.**—Mix in a flask about 7 cc. of Solution of Chlorinated Soda, accurately weighed, with 50 cc. of distilled water, add 1 Gm. of potassium iodide and 5 cc. of acetic acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, starch T.S. being used as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003546 Gm. of Cl.

" Preserve in well-stoppered bottles, in a cool place, protected from light." *U. S.*

" A colorless alkaline liquid with a faint odor of chlorine and astringent taste. Decomposed by *hydrochloric acid,* evolving chlorine. Yields not more than slight *reactions* for calcium or carbonates. Specific gravity 1.054. If 5 millilitres are added to a solution of 1 gramme of *potassium iodide* in 100 millilitres of *water* acidified with 5 millilitres of *hydrochloric acid,* a brownish-red solution is obtained, which requires for decolorisation not less than 37.6 millilitres of *N/10 solution of sodium thiosulphate* (presence of not less than 2.5 per cent. by weight of available chlorine)." *Br.*

The two official assays are essentially similar.

Assuming the chlorinated lime to be essentially calcium hypochlorite with calcium chloride, the solutions, after decantation from the precipitated calcium carbonate, will contain *sodium hypochlorite* with sodium chloride:

$$Ca(OCl)_2 + CaCl_2 + 2Na_2CO_3 = 2CaCO_3 + 2NaOCl + 2NaCl$$

Besides these there will be present more or less sodium carbonate, according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of sodium carbonate, as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula.

Arny and Dawson (*Proc. A. Ph. A.,* 1908, p. 841) criticized the process for making this solution and recommended the reduction of the U. S. P. standard for chlorinated lime from 30 per cent. of available chlorine to 25 per cent. largely because it is difficult for pharmacists to procure the drug commercially of this strength.

Uses.—The solution of chlorinated soda possesses the germicidal value of its available chlorine. For the disinfection of large masses of organic matter it is inferior to chlorinated lime, not merely because of its greater cost, but also because of its lower content of chlorine. It is, however, an excellent agent for the disinfection of various utensils which are not injured by its bleaching action, such as clinical thermometers and glass or china ware which have been used by patients with contagious disease.

Under the name of *antiformin* an alkaline solution of sodium hypochlorite is largely used in the bacteriological laboratory. This solution contains about 7.5 per cent. of sodium hydroxide and 5.2 per cent. of chlorine. Its especial value lies in its property of liquefying various organic matters and of dissolving most varieties of bacteria. It is especially employed for the purpose of recognizing tubercle bacilli in the sputum; it liquefies the sputum, so that centrifugation is possible, and dissolves other bacteria.

LIQUOR SODÆ CHLORINATÆ CHIRURGICALIS. U. S.

SURGICAL SOLUTION OF CHLORINATED SODA

Liq. Sod. Chlorinat. Chir. [Modified Dakin's Solution]

"An aqueous solution of chlorine compounds of sodium, containing not less than 0.45 per cent. and not more than 0.50 per cent. of NaOCl equivalent to from 0.43 to 0.48 per cent. of available Cl." *U. S.*

Dakin's Solution, Carrel-Dakin's Solution, Solution of Sodium Hypochlorite.

"Chlorinated Lime, Exsiccated Sodium Phosphate, Water, each, a sufficient quantity to make 1000 cc. Assay the chlorinated lime (see *Calx Chlorinata*) and, having determined its percentage of available chlorine, prepare the solution as directed below, using the quantities of chlorinated lime and exsiccated sodium phosphate indicated in the following table:

Per cent of available chlorine in the chlorinated lime used	Gm. of chlorinated lime for each 1000 cc. of solution	Gm. of exsiccated sodium phosphate for each 1000 cc. of solution
20	29	38
21	28	36
22	27	34
23	26	32
24	25	30
25	24	28
26	23	26
27	22	24
28	21	22
29	20.5	21
30	20	20
31	19.5	20
32	19	20
33	18	20
34	17.5	20
35	17	20

"Triturate the necessary amount of chlorinated lime, as indicated by the table, with 400 cc. of water gradually added, until a uniform mixture results. Dissolve the required amount of exsiccated sodium phosphate, which has been recently dried, in 400 cc. of water, heated to 50° C., and add this solution to the chlorinated lime mixture. Shake thoroughly and allow it to stand for fifteen minutes. Transfer the mixture to a filter, returning the first portions of filtrate until it runs through clear, and when no more liquid drains from the filter, wash the precipitate with sufficient water to make the product measure 900 cc. Assay a portion as directed below, and dilute the remainder with sufficient water to make the finished Solution contain 0.48 per cent. of NaOCl." *U. S.*

In 1915 as a result of experiences in the treatment of gun shot wounds in the great European War, Doctor Dakin called attention to the value of a solution of chlorinated soda neutralized with boric acid (*B. M. J.,* 1915, ii, p. 318). His original formula was soon afterwards modified by Doctor Carrel. Subsequently a considerable number of modifications of these solutions have been suggested, but they are all known generically as *Carrel-Dakin solutions* and they all depend for their activity upon the presence of definite proportions of sodium hypochlorite.

It is important that this solution be clearly distinguished from the old Labarraque's solution. It differs in the first place in being much weaker, secondly in containing definite proportions of available chlorine by assay, and thirdly in being free from caustic alkali. It is important to note that in some cases the strength of the solution is expressed in parts per cent. of sodium hypochlorite. This has caused considerable confusion in statements concerning advisable concentrations. Sodium hypochlorite represents 47.65 per cent. of chlorine, all of which is capable of being liberated in oxidation reactions. In such reactions each chlorine atom is equivalent to one oxygen atom, so "available chlorine" is simply a trade expression in which the figure representing the replaceable chlorine is multiplied by 2. This makes the available chlorine content of sodium hypochlorite at about 95 per cent., so in this case there is little difference between the strengths as expressed in terms of sodium hypochlorite, or as available chlorine.

The formula as originally given by Dakin (*B. M. J.*, 1915, ii, p. 318) is as follows: 140 Gm. of dry sodium carbonate (or 400 Gm. of the crystalline) are dissolved in 10 liters of tap water. Add 200 Gm. of chlorinated lime and shake well. Half an hour later siphon off the clear fluid and filter through cotton. Add 40 Gm. of boric acid, which should yield a solution only faintly alkaline. This solution represents, according to Dakin, between 0.5 to 0.6 per cent. of sodium hypochlorite. Later Dr. A. Carrel submitted a formula for what is called "*Carrel-Dakin Solution*" (Daufresne's technic), which largely replaced the original. Numerous other formulas have been suggested, the most widely used directing the use of sodium bicarbonate as the neutralizing and stabilizing ingredient. In the official process this has been replaced by exsiccated sodium phosphate, the process being based on one that has been used for some years with satisfaction at the Johns Hopkins Hospital in Baltimore.

Description and Physical Properties.—"A colorless or faintly yellow liquid having a slight odor suggesting chlorine. Add about 0.02 Gm. of powdered phenolphthalein to 20 cc. of Surgical Solution of Chlorinated Soda: no red color is produced on agitation (*maximum alkalinity*). Add about 0.5 cc. of phenolphthalein T.S. to 5 cc. of the Solution contained in a test tube: a momentary red flash is produced (*minimum alkalinity*).

"**Assay.**—Dilute 25 cc. of the Solution, accurately weighed, with 50 cc. of distilled water, add 1 Gm. of potassium iodide and 5 cc. of acetic acid, and titrate the liberated iodine with tenth-normal sodium thiosulphate, using starch T.S. as indicator. Each cc. of tenth-normal sodium thiosulphate corresponds to 0.003723 Gm. of NaOCl.

"Preserve in well-stoppered bottles, preferably for not more than seven days, in a cool place, protected from light." *U. S.*

Cullen and Taylor (*J. A. M. A.*, June 15, 1918) point out that the end point indicated by phenolphthalein is not neutrality but a distinct alkalinity; as too great alkalinity makes the solution irritant they recommend the use of some other indicator such as o-cresolphthalein (see under *Indicators*).

Some of the commercial solutions of sodium hypochlorite, which are intended for the extemporaneous preparation of solutions similar in character to Dakin's solution, are of a remarkably high degree of stability. Whether this be due to the presence of some preservative or to some unusual method of manufacture or to an extraordinary purity, can not be stated at this time.

Sherman (*J. A. M. A.*, 1917, lxix, 187) tested stability of Dakin's solution: Exposed to sunlight there was a notable loss of strength within a week, the solution dropping from 0.52 per cent. of NaOCl to 0.49 per cent.; the same original solution, kept in the dark, at the end of 40 days showed 0.50 per cent. of NaOCl. Becker also (*J. A. Ph. A.*, 1925, xiv, 129) reached the conclusion that daylight had a marked deteriorating effect on this solution but that heating did not affect its potency. According to Chevrier (*D. C.*, 1918, lxii, 263) contact with rubber tubing causes rapid deterioration; from 43 to 39 in 12 hours. Daufresne adds a trace of potassium permanganate, 5 milligrammes per liter, to stabilize Dakin's solution (*C. D.*, 1918, xc, 184).

Under the name of *Eusol*, an aqueous solution of hypochlorous acid has been used in the same manner as the sodium hypochlorite.

Hyclorite (*N. N. R.*, 1924) is a commercial solution which is stated to contain 4.05 per cent. of sodium hypochlorite, .025 per cent. of calcium hydroxide and to represent not less than 3.85 per cent. of available chlorine. It is, therefore, approximately seven or eight times as strong as the official solution. *Zonite* is another commercial solution of sodium hypochlorite, which is claimed by the manufacturers to contain 0.9 per cent. of available chlorine and therefore to be twice as strong as the official solution. These solutions are, like Dakin's solution, disinfectant. They do not, however, possess all of the characteristic properties and must never be used as substitutes for the official preparation where this is ordered.

The peculiar therapeutic virtues of Dakin's solution depend on a special combination of certain chemical properties, namely (1) a definite concentration of sodium hypochlorite; either too much or too little destroys its value and (2) the complete absence of caustic alkali, with, however, a feebly alkaline reaction. These qualities can be produced only by the most rigid adherence to the details of the formula. The practice, at one time not uncommon, of dispensing solutions of chloramine in the place of Dakin's solution is a sordid type of dishonesty fraught with the possibility of most serious danger to the patient. (See Smyth, *A. J. P.*, 1923, p. 232.)

Uses.—Dakin's solution is used solely for its antibacterial properties especially in the treatment of surgical *wounds*. Tilley (*J. Agricult. Research*, 1920, xx, p. 85) has shown that sodium hypochlorite in germicidal power ranks with bichloride of mercury. In the absence of organic material one part in 25,000 kills most non-sporulating bacteria, and one part in 200 killed the highly resistant anthrax spores after two hours. In the presence of blood serum, however, the germicidal action is very much weaker, a one to 400 solution requiring two hours to kill the ordinary vegetative forms; this latter strength is approximately equivalent to 50 per cent. of the official surgical solution. The peculiar value of this solution in surgery depends, however, not merely on its antibacterial action, but to a large extent upon its power of dissolving necrotic tissue, and hence aid in getting rid of undesirable detritus. This solvent power, however, may become very dangerous in some conditions. Chevrier (*D. C.*, 1918, lxii, p. 212) points out the danger of secondary hemorrhage from dissolving of ligature material, and Sheldon (*P. J.*, 1918, ci, p. 150) has demonstrated a solvent action upon catgut, silkworm gut, silk thread and horse hair; he found linen thread much more resistant. Frequently the solution is applied by a method of continuous irrigation, in which case care must be observed to protect the skin surrounding the wounded area. It is sometimes used for irrigation of internal cavities like the bladder. It is employed in concentrations ranging from full strength down to one in four according to the condition for which it is applied.

LIQUOR SODII ARSENATIS. Br.

SOLUTION OF SODIUM ARSENATE Liq. Sod. Arsen.

Liquor Sodii Arseniatis, *Br.* 1885; Solution of Arseniate of Sodium; Natrium Arsenicicum Solutum; Solutio Arsenatis Natrii; Soluté d'Arseniate de Soude, *Fr.*; Arsensaure Natronlösung, *G.*

"Anhydrous Sodium Arsenate, 1 *gramme;* Distilled Water, sufficient to produce 100 *millilitres.* Dissolve. This Solution contains the equivalent of 1 gramme of Anhydrous Sodium Arsenate in 100 millilitres; 110 minims contain the equivalent of 1 grain." *Br.*

The salt is directed to be dried, in order that the solution may be of a uniform strength, as, from the mode in which the sodium arsenate is ordered to be prepared, it is scarcely possible that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 150° C., lest a portion of the arsenic should be volatilized.

Dose, from three to five minims (0.2–0.3 cc.), to be cautiously increased, if necessary.

LIQUOR SODII CHLORIDI PHYSIOLOGICUS. U. S.

PHYSIOLOGICAL SOLUTION OF SODIUM CHLORIDE Liq. Sod. Chlor. Physio. [Physiological Salt Solution Normal Saline Solution]

"Sodium Chloride, 8.5 Gm.; Distilled Water, a sufficient quantity to make 1000 cc. Dissolve the sodium chloride in sufficient freshly distilled water, neutral to litmus paper, to measure 1000 cc., and filter, returning the filtrate until free from foreign particles. Transfer the solution to a sterile flask of insoluble glass, having a capacity of about 1000 cc., and stopper with a plug of purified absorbent cotton, wrapped in gauze. Fasten stout, non-absorbent paper or tinfoil over the top of the plug and the lip of the container, and sterilize in an autoclave under steam pressure maintaining a temperature of 115° C., for thirty minutes. This solution should be used within twenty-four hours if it is to be employed for intravenous injection. For other uses it is preferable that the solution be resterilized after each opening, and that it be used within a month after its preparation." *U. S.*

The Pharmacopœia directs that salt solution be sterilized in an autoclave; the previous recommendation was to boil it for one hour. If this be done a considerable amount of the water may be evaporated and the concentration of the solution materially altered. It is advisable to sterilize the container separately by dry heat as it is possible some spores might resist the autoclave temperature.

Uses.—When pure water is brought in contact with the blood it causes alteration in the red blood corpuscles, allowing the escape of hemoglobin from them into the plasma; this is known as "laking" of the blood. The addition of inorganic salts to the water, in quantities sufficient to make a solution of the same osmotic tension as the blood serum, prevents this action on the corpuscles. When a solution contains just the amount of salt necessary to prevent laking it is said to be isotonic with the blood. Because of its non-toxicity sodium chloride is the salt usually employed for the purpose of preparing an isotonic solution. The amount of salt necessary for this purpose varies in different animals; in the human being it requires an 0.85 per cent. solution of sodium chloride, but an 0.6 per cent. is isotonic with ox blood. This isotonic solution is sometimes spoken of as *normal salt solution,* an unfortunate term, as it is likely to be confused with the normal volumetric solution of sodium chloride used by chemists, which is nearly seven times stronger. A much better term is the official name, *physiological salt solution.* In 1882 Ringer showed that after all the blood has been washed out of the heart with an isotonic sodium chloride solution, the addition of small amounts of calcium and potassium would cause that organ again to begin to contract, and that it would continue beating for some time if supplied with these salts. He therefore suggested that calcium and potassium be added to the sodium chloride solution in preparing a physiologically indifferent fluid. Although Ringer originally recommended the addition of calcium phosphate to saturation for the purpose of supplying the needed lime, as at present used in physiological laboratories *Ringer's solution* has the following composition: sodium chloride, 0.7 per cent.; potassium chloride, 0.03 per cent.; calcium chloride, 0.025 per cent. Subsequently it was shown that if this solution was rendered slightly alkaline it offered a still more favorable medium for the heart. In 1895 Locke suggested the addition of dextrose in order to furnish a food stuff to the heart. *Locke's solution* (see also *Locke-Ringer's solution,* Part III), which is widely used in physiological laboratories, contains: sodium chloride, 0.9 Gm.; calcium chloride, 0.024 Gm.; potassium chloride, 0.042 Gm.; sodium bicarbonate, 0.02 Gm.; dextrose, 0.1 Gm.; water, 100 cc. A still more recent modification known as *Tyrode's solution* has the following combination: sodium chloride, 0.8 per cent.; potassium chloride, 0.02; calcium chloride, 0.02; magnesium chloride, 0.01; sodium phosphate, 0.005; sodium bicarbonate, 0.1 per cent. Although theoretically these solutions are preferable to that of simple sodium chloride, because more nearly approximating the composition of the bodily fluids, yet practically the reserve supply of calcium and potassium in the human body is so large that it is extremely doubtful whether they are ordinarily superior for medical purposes. Mellon and his co-workers (*J. A. M. A.*, 1922, lxxviii, p. 1026) believe that many of the unpleasant reactions which have followed the intravenous injection of large amounts of physiological salt solutions have been due to abnormal hydrogen-ion concentration—that is, incomplete neutrality. This is due in part to the acidity which is developed in distilled water by boiling and in part to the fact that sodium chloride of the market is generally not absolutely neutral. They suggest, to guard against these effects, the use of a mixture of monobasic and dibasic sodium phosphates as buffer salts; these must be added after sterilization as they are likely to be precipitated by boiling.

Physiological salt solution is used for the purpose of introducing large quantities of water into the system more rapidly than could be done through the alimentary tract. In cases of low blood pressure due either to severe *hemorrhage*—in which the volume of blood is so greatly reduced as to be unable to properly fill the blood vessels—or due to vasomotor paresis, such as *surgical shock*—when the vessels are so dilated that the normal quantity of blood is unable to fill them—the introduction of large amounts of blood into the circulation, as by intravenous injection of physiological salt solution, by filling the vascular system restores a normal resistance and thereby tends to bring the blood pressure back to the normal. While this venoclysis has temporarily a very beneficial effect, it has been found that the fluid escapes from the vessels so rapidly that its practical value is open to question. Various substances such as acacia, gelatin or glucose have been added with the idea that an increase of viscosity would lessen the escape of the water. A discussion of the details of these solutions and of the related blood transfusions is, however, somewhat foreign to the field of this work, and the reader is referred to books on surgical technic.

In cases of severe dehydration of the body—as in the violent purgation of *Asiatic cholera* or *arsenic poisoning*—the administration of salt solution by increasing the volume of blood is often of much benefit. As is well known, the volume of the urine and of the sweat depends in large measure upon the volume of the blood and the introduction of large quantities of fluid, as by the injection of physiological salt solution, tends to increase these secretions. It is probable that the increased output of water under these circumstances will carry with it certain toxic substances, and the method of treatment is widely used in certain cases of systemic poisoning, such as *uremia,* with the idea of increasing the elimination of the toxic material. It is more likely, however, that the benefit from the injection of fluids in cases of extraneous poisonings, such as *corrosive sublimate* or *lead poisoning,* is due more to the dilution of the blood than to the actual increase in elimination.

Physiological salt solution may be administered either intravenously, subcutaneously (*hypodermoclysis*), or through the colon (*enteroclysis*). Absorption through the last channel is relatively slow and enteroclysis is employed chiefly in those conditions where it is desirable to avoid the administration of water by the mouth. In either hypodermic or intravenous injection it is essential that the salt solution be absolutely sterile. For this reason it is necessary not only that the solution be made with freshly distilled water, but that it should be resterilized after the addition of the sodium chloride. It is, of course, equally essential that the vessels used for the injection, and also the skin of the patient, should also be properly sterilized. From one pint to two quarts (500–1900 cc.) of the physiological salt solution may be injected at one dose and repeated again if necessary in a few hours.

LIQUOR SODII HYDROXIDI. U. S.

SOLUTION OF SODIUM HYDROXIDE Liq. Sod. Hydrox. [Liquor Sodæ, U. S. 1890, Solution of Soda]

"Solution of Sodium Hydroxide contains, in each 100 cc., not less than 4.5 Gm. and not more than 5.5 Gm. of NaOH." *U. S.*

Liquor Sodæ, *U. S.* 1890; Solution of Soda; Solution of Caustic Soda; Natrium Hydricum Solutum; Soude caustique liquide, Lessive des Savonniers, *Fr.;* Liquor Natri Caustici, *P. G.;* Aetznatronlauge, Natronlauge, *G.;* Solucion de sosa caustica, *Sp.*

"Dekanormal Solution of Sodium Hydroxide, 125 cc.; Distilled Water, a sufficient quantity to make 1000 cc. Mix the dekanormal solution (page 1573) with sufficient distilled water to make 1000 cc. NOTE.—The 125 cc. of dekanormal solution of sodium hydroxide may be replaced by 56 Gm. of sodium hydroxide, containing 90 per cent. of NaOH." *U. S.*

Description and Physical Properties.—"A clear, colorless, odorless liquid, strongly alkaline and caustic. It readily absorbs carbon dioxide from the air. Specific gravity: about 1.056 at 25° C. It meets the requirements of the tests for identity and purity for an aqueous solution of sodium hydroxide under *Sodii Hydroxidum,* when suitably concentrated. Measure exactly 20 cc. of Solution of Sodium Hydroxide into a suitable flask and titrate directly with normal hydrochloric acid, using methyl orange T.S. as indicator: it shows, in each 100 cc., not more than 5.5 Gm. of alkali, calculated as NaOH (*carbonate*).

"**Assay.**—Measure exactly 50 cc. of Solution of Sodium Hydroxide into a 250 cc. measuring flask, add 20 cc. of barium chloride T.S., and fill the flask to the mark with recently boiled distilled water. Thoroughly agitate the liquid, filter it through a filter not previously moistened, reject the first 20 cc., and titrate 100 cc. of the filtrate, representing 20 cc. of the Solution, with normal hydrochloric acid, using phenolphthalein T.S. as indicator. Each cc. of normal hydrochloric acid corresponds to 0.04001 Gm. of NaOH.

"Preserve in bottles made of hard glass and provided with rubber stoppers or with glass stoppers coated with petrolatum." *U. S.*

Its properties and tests are the same as those of solution of potassium hydroxide, with the exception that no precipitate is produced by platinic chloride or tartaric acid.

Uses.—The solution of sodium hydroxide is mildly caustic and actively antacid. For most of the local uses for which caustic soda is employed it is generally too feeble, while for internal administration it is too irritant to the stomach and is rarely employed as a medicine.

Dose, ten to thirty minims (0.6–1.8 cc.).

LIQUOR STRYCHNINÆ HYDROCHLORIDI. Br.

SOLUTION OF STRYCHNINE HYDROCHLORIDE
[Solution of Hydrochlorate of Strychnine, Brit. Pharm. 1885]

Liquor Strychniæ; Soluté de Chlorhydrate de Strychnine, *Fr.;* Salzsaure Strychninlösung, *G.*

"Strychnine Hydrochloride, 1 *gramme;* Alcohol (90 per cent.), 25 *millilitres;* Distilled Water, sufficient to produce 100 *millilitres.* Mix the Alcohol with an equal volume of Distilled Water; dissolve the Strychnine Hydrochloride in the mixture, and add sufficient Distilled Water to produce the required volume. This Solution contains 1 gramme of Strychnine Hydrochloride in 100 millilitres; 110 minims contain 1 grain." *Br.*

This is the solution of hydrochloride of strychnine of the British Pharmacopœia which was formerly official as *Liquor Strychniæ;* the name has been made definite, and the strength slightly increased, so as to make it conform with the other active solutions; it contains about 1 per cent. of strychnine. The spirit is added for its preservation.

Dose, from three to six minims (0.2–0.4 cc.), equal respectively to about one-thirtieth and one-eighteenth of a grain (0.002–0.004 Gm.) of the alkaloid.

LIQUOR ZINCI CHLORIDI. U. S., Br.

SOLUTION OF ZINC CHLORIDE Liq. Zinc. Chlor.

"Solution of Zinc Chloride is an aqueous solution containing not less than 48.5 per cent. nor more than 52 per cent. of $ZnCl_2$." *U. S.*

Chlorure de Zinc liquide, Soluté de Burnett, *Fr.;* Flüssiges Chlorzink, Chlorzinklösung, *G.*

No process is given in the U. S.; that of the Br. is as follows:

"Granulated Zinc, 400 *grammes;* Hydrochloric Acid, 1100 *millilitres;* Distilled Water, *a sufficient quantity.* Mix the Hydrochloric Acid with five hundred *millilitres* of Distilled Water in a porcelain dish; add the Zinc; apply gentle heat until gas is no longer evolved; boil for half an hour, supply the water lost by evaporation; allow the product to cool. Test a few drops of the resulting liquid for iron and lead. If either be present, filter the remainder of the cooled product into a bottle, and add *solution of chlorine* by degrees, with frequent shaking, until the liquid acquires a permanent odor of chlorine; add Zinc Carbonate in small quantities at a time, with renewed shaking until the whole of the iron or lead is precipitated; filter the liquid and evaporate to one thousand millilitres. If no iron or lead be present, filter the remainder of the cooled product, and evaporate it to one thousand millilitres." *Br.*

The zinc chloride is made in the usual way, by dissolving zinc in hydrochloric acid. The commercial zinc is often contaminated with iron. In the Br. process the iron, if present, is converted into ferric chloride by the addition of chlorine solution and then precipitated by alkalizing with zinc carbonate. In the former process of the U. S. IX nitric acid was added which, by its oxidizing effect, assured the conversion of the iron into ferric chloride. Hydrogen dioxide has been used instead of nitric acid as an oxidizing agent by Besthorn and others. The preparation is completed by bringing it to a certain weight by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of the carbonate. On account of the difficulty of freeing zinc from iron contamination, Francis Hemm proposes the simpler process of making this solution from iron-free zinc oxide; he dissolves 300 Gm. of such zinc oxide in 840 Gm. of hydrochloric acid in a porcelain dish, with the aid of heat, cools, filters, and evaporates the filtrate to 1000 Gm. (*Am. Drug.,* 1900, 199.)

Description and Physical Properties.—"A clear, colorless or slightly yellow, odorless, caustic liquid. It is strongly acid to litmus paper. Specific gravity: about 1.548 at 25° C. Solution of Zinc Chloride responds to the reactions for zinc, and for chlorides, and meets the requirements of the tests for purity for an aqueous solution of the salt under *Zinci Chloridum,* when taken in proportionate amount.

"**Assay.**—Place in a tared flask about 0.5 cc. of Solution of Zinc Chloride, weigh accurately, and proceed as directed under the Assay for chlorides. Each cc. of tenth-normal silver nitrate corresponds to 0.006815 Gm. of $ZnCl_2$." *U. S.*

"A colorless liquid; taste astringent and sweetish. Specific gravity 1.530. Yields no characteristic *reactions* for lead, copper, cadmium, arsenic, iron, aluminium, calcium, magnesium, or sulphates." *Br.*

Uses.—The solution of zinc chloride is actively caustic and a powerful germicide, possessed of deodorant properties. In dilute solution it acts as a stimulating astringent with some antiseptic powers. It has been employed, either in full strength or with equal parts of water, for the destruction of *cancerous ulcers,* especially when there is fetid discharge. It has, however, the disadvantages that it destroys healthy as well as diseased tissue and that its action is accompanied with a considerable amount of pain. In dilute solution it is used for its astringent and antiseptic influence in *gleet, vaginitis* and, occasionally, in inflammations of the other mucous membranes; for these purposes it may be employed in strengths of from 1 to 5 per cent. Formerly the solution of zinc chloride was largely used as a general disinfectant both for surgical and sanitary purposes but has been largely replaced by other agents. It is also commonly used for the preservation of bodies for dissection. *Burnett's Disinfecting Fluid* was an aqueous solution of zinc chloride very similar to the present official solution; as originally recommended it was made by dissolving one pound of zinc chloride in five gallons of water, but was commercially often prepared by the natural deliquescence of the crystals.

LIQUORES.

SOLUTIONS

Solutés, *Fr.;* Liquores, *P. G.;* Lösungen, *G.;* Soluzione, *It.;* Solucion, *Sp.*

The U. S. Pharmacopœia includes in this class of preparations all aqueous solutions without sugar in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the Aquæ, or Waters. The British Pharmacopœia does not make this distinction and includes several alcoholic solutions of volatile principles among the liquors.

The Br. Pharm., 1898, introduced ten concentrated infusions, with the object of affording an easy method of making, through dilution, ordinary infusions. The titles were very inappropriate, and the British Pharmacopœia, 1914, dismissed *concentrated infusions.*

LITHII BENZOAS. N. F.

LITHIUM BENZOATE Lith. Benz.

"Lithium Benzoate contains, when dried for 24 hours over sulphuric acid, not less than 98.5 per cent. of $LiC_7H_5O_2$ (128.01)." *N. F.*

Benzoas Lithicus; Benzoate de Lithium, *Fr.;* Lithium Benzoicum, *Fr. Cod.;* Bromsäure Lithium, *G.*

This salt may be made by the action of benzoic acid upon lithium. It was at one time recognized by the Pharmacopœia but was dropped at the ninth revision. It has been made official in the N. F.

Description and Physical Properties.—"A white powder or small crystalline scales. It is odorless, and is stable in the air. One Gm. of Lithium Benzoate dissolves in about 3 cc. of water and in about 16 cc. of alcohol at 25° C. It is slightly more soluble in these solvents when hot.

"When heated the salt at first fuses, then at higher temperatures it chars, emitting inflammable vapors having a benzoin-like odor and finally leaves a residue of lithium carbonate and carbon. This residue is alkaline to litmus paper, effervesces with acids and colors a non-luminous flame crimson. The addition of mineral acids to an aqueous solution of Lithium Benzoate (1 in 20) produces a voluminous white precipitate of benzoic acid. Ferric chloride added to the aqueous solution produces a flesh colored precipitate of ferric benzoate.

"Dissolve 0.6 Gm. of Lithium Benzoate in 25 cc. of water, add 5 cc. of diluted hydrochloric acid, filter and wash the precipitate with about 25 cc. of distilled water. Evaporate the combined filtrate and washings on a water bath to a small volume in a beaker or dish, then transfer completely with the aid of a little water into a flat-bottomed flask of about 50 cc. capacity and evaporate almost to dryness on a water bath. Add 10 cc. of amyl alcohol and cautiously heat the mixture until all the water has evaporated. The removal of the water from the amyl alcohol mixture may be facilitated by passing a current of air through the hot solution. Then add 3 drops of hydrochloric acid and boil the solution for 3 minutes. If any insoluble residue remains, collect it on a filter, wash it with amyl alcohol and dry at 110° C. to constant weight. The weight of the residue should not exceed 0.004 Gm. (other *alkalies*). Dissolve about 1 Gm. of Lithium Benzoate in 20 cc. of water in a separatory funnel, add 10 cc. of diluted sulphuric acid, extract the precipitate of benzoic acid by shaking with 2 portions of 20 cc. each of ether, and evaporate the ether solution to dryness at a low temperature. One half Gm. of the residue of benzoic acid thus obtained complies with the test for *chlorine* described in the U. S. P. under *Acidum Benzoicum.* The aqueous layer from the above test, warmed to expel ether and diluted to 50 cc. does not respond to the test for *heavy metals.*

"**Assay.**—Weigh accurately about 0.5 Gm. of

Lithium Benzoate, which has previously been dried for 24 hours over sulphuric acid, mix it with 1 Gm. of dried and powdered ammonium sulphate and cautiously ignite in a porcelain crucible to constant weight. The weight of the residue of lithium sulphate thus obtained, multiplied by 2.328, represents its equivalent of Lithium Benzoate." *N. F.*

According to Curtman, lithium benzoate is often contaminated with sodium benzoate which increases its solubility.

Uses.—Lithium benzoate possesses the therapeutic virtues of the other benzoates (see *Sodii Benzoas*), but it is not apparent that it possesses any advantage over the sodium salt.

Dose, from ten to twenty grains (0.6–1.2 Gm.).

Off. Prep.—Elixir Hydrangeæ et Lithii, *N. F.*

LITHII BROMIDUM. N. F.

LITHIUM BROMIDE Lith. Brom.

"Lithium Bromide contains, when dried for twenty-four hours over sulphuric acid, not less than 85 per cent. of LiBr (86.86)." *N. F.*

Lithium Bromatum; Bromure de Lithium, *Fr.;* Bromlithium, Lithiumbromid, *G.*

Yvon prepares *lithium bromide* by mixing 37 parts of lithium carbonate, 200 parts of distilled water, and 80 parts of bromine, and passing a current of hydrogen sulphide through the mixture until the color of bromine has disappeared. A slight heat is then applied, to drive off excess of hydrogen sulphide and to agglutinate the sulphur. After filtration the liquor is concentrated and finally crystallized by desiccating it under a bell glass, over sulphuric acid. It may also be obtained by double decomposition between lithiun sulphate and potassium bromide in the presence of water and a little alcohol.

Description and Physical Properties.—"Lithium Bromide is a white, granular salt, odorless and having a sharp, slightly bitter taste; very deliquescent. One Gm. of Lithium Bromide dissolves in 0.6 cc. of water at 25° C.; also in 0.4 cc. of boiling water; freely soluble in alcohol and soluble in ether.

"An aqueous solution of the salt (1 in 20) is neutral or slightly alkaline to litmus. At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame. Add to 10 cc. of a solution of Lithium Bromide (1 in 20) a slight excess of chlorine T.S., then add 5 cc. of chloroform and shake the mixture, the chloroform separates with a red or reddish brown color.

"Add a few drops of ferric chloride T.S. and 1 cc. of chloroform to 10 cc. of an aqueous solution of the salt (1 in 20) and shake the mixture. The chloroform does not acquire a violet tint (*iodide*). Drop 1 cc. of diluted sulphuric acid on about 1 Gm. of the powdered salt; no yellow color appears at once (*bromate*). Dissolve about 0.1 Gm. of Lithium Bromide in 5 cc. of distilled water, add an excess of silver nitrate T.S. and a few drops of nitric acid; filter and wash the precipitate with distilled water, then digest it for ten minutes with 5 cc. of ammonium carbonate T.S. and filter. Dilute the filtrate to 40 cc. and supersaturate with nitric acid, not more than a slight turbidity is produced at once (*chloride*). Five cc. of an aqueous solution of the salt (1 in 100) acidulated with 4 drops of hydrochloric acid shows no immediate turbidity with 1 cc. of barium chloride T.S. (*sulphate*). Add 5 cc. of hydrochloric acid and 5 cc. of chlorine T.S. to 0.4 Gm. of Lithium Bromide contained in a flat-bottomed flask of 50 cc. capacity, evaporate the mixture almost to dryness on a water-bath, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes; the resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.002 Gm. (*other alkalies*). The removal of water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. An aqueous solution of the salt does not respond to the Test for heavy metals.

"**Assay.**—Introduce into a tared weighing-bottle about 0.35 Gm. of Lithium Bromide, previously dried for twenty-four hours over sulphuric acid, stopper, weigh accurately, and proceed as directed under the Assay for bromides. Each cc. of tenth-normal silver nitrate corresponds to 0.008686 Gm. of LiBr. Each Gm. of Lithium Bromide corresponds to not less than 97.9 cc. of tenth-normal silver nitrate.

"Preserve it in air-tight containers." *N. F.*

Uses.—Lithium bromide was first brought into notice as a remedy by S. Weir Mitchell, who asserts that its action differs from that of the other bromides only in being more hypnotic. Although careful physiological studies of it are wanting, there is little reason for believing that it differs essentially from other bromides in its influence upon the human organism. It should be administered in dilute aqueous solution. Each drachm of it contains fifty-five grains of bromine, and it therefore exceeds potassium bromine in bromine strength.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Elixir Bromidorum Quinque, *N. F.;* Syrupus Bromidorum, *N. F.*

LITHII CARBONAS. N. F., Br.

LITHIUM CARBONATE Lith. Carb.

"Lithium Carbonate contains, when dried to constant weight at 100° C., not less than 98.5 per cent. of Li_2CO_3(73.89)." *N. F.*

"Lithium Carbonate may be obtained from native silicates of lithium. It contains not less than 98.5 per cent. of pure lithium carbonate, Li_2CO_3." *Br.*

Carbonas Lithicus; Carbonate of Lithia; Carbonate de Lithine, Carbonate lithique, *Fr.;* Lithium Carbonicum, *P. G.;* Lithiumcarbonat, Kohlensaures Lithium, *G.;* Carbonato di litio, *It.;* Carbonato de litina o litico, *Sp.*

Lithium was discovered by Arfvedson in 1817, in certain minerals from the iron mines of Utö, as *petalite, triphane,* and a variety of *tourmaline.* (Berzelius.) It has since been found in other minerals, as *lepidolite, spodumene, amblygonite,* etc., and in numerous mineral waters, as those of Carlsbad, Salsomaggiore, Pyrmont, Kissingen, Kreuzmach, Aix-la-Chapelle, Vichy, etc., in Europe, and the Gettysburg spring in the United States, in which it exists generally as a carbonate or a bicarbonate. By spectrum analysis it has been detected in the waters of the Atlantic Ocean and of the Thames, the Delaware, the Potomac and many other rivers; in the ashes of plants grown on a granite soil, and even in milk and human blood. In the mother waters of tartaric acid, in the factories, it has been found in a proportion to justify extraction. It was at one time largely obtained from a *phosphatic triphyline* found in Bavaria, in which it existed as a phosphate, but this source is said to have been exhausted. There are several methods of extracting lithia from the minerals containing it, an account of which may be seen in *Roscoe and Schorlemmer,* vol. ii, Part I, page 158. Lithium carbonate is prepared from lepidolite in the following manner. Ten parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a wind furnace. The heavy barium silicate and sulphate sink to the bottom, and a layer of potassium and lithium sulphates is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate.

In another process the lepidolite is digested with hot sulphuric acid which produces the sulphates of aluminum and lithium principally, and these are separated by crystallization or precipitation operations.

The element which was first separated and purified by Bunsen and Matthiessen, in 1855, is silver-white, brilliant, softer than lead, ductile, capable of welding, and the lightest known metallic element. Its sp. gr. is 0.594, melting point 180° C., atomic weight 6.94, and symbol Li. For a method of making lithium for scientific demonstration on the small scale by electrolysis, see *Ph. Rev.,* 1899, 264.

Lithium carbonate may be prepared from lithium sulphate or chloride in concentrated solution by adding ammonium carbonate. The precipitated salt should be washed with alcohol and dried.

Description and Physical Properties.—"Lithium Carbonate is a light, white powder, odorless, and having an alkaline taste; permanent in the air. One Gm. of Lithium Carbonate dissolves in 78 cc. of water at 25° C.; also in 140 cc. of boiling water; almost insoluble in alcohol; dissolved by diluted acids with effervescence.

"At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. It imparts a crimson color to a non-luminous flame. A saturated aqueous solution of the salt is alkaline to litmus and effervesces when acid is added.

"Lithium Carbonate when dissolved in 40 parts of diluted acetic acid, leaves not more than 0.15 per cent. of insoluble residue. Mix 1 part of Lithium Carbonate with 20 parts of distilled water and add hydrochloric acid, drop by drop, with agitation until solution takes place. The resulting solution, after boiling and cooling, responds to the following tests when applied to separate portions: The addition of ammonia water to 5 cc. of this solution until it has an alkaline reaction produces neither turbidity nor precipitation either before or after boiling (*iron, aluminum*). Dilute another portion of 4 cc. of this solution with 6 cc. of distilled water; it does not respond to the test for heavy metals. Add a slight excess of diluted hydrochloric acid to 0.2 Gm. of Lithium Carbonate contained in a flat-bottomed flask of 50 cc. capacity, evaporate the mixture almost to dryness on a water bath, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.002 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution." *N. F.*

"White powder, or minute crystalline grains. Taste slightly alkaline. Soluble in 80 parts of *water;* insoluble in *alcohol* (90 per cent.). Aqueous solution alkaline to *litmus.* Soluble with effervescence in *hydrochloric acid;* the solution evaporated to dryness leaves a residue which communicates a crimson color to flame, and, redissolved in *water,* yields a precipitate with *solution of sodium phosphate.* 1 gramme, diffused in about 50 millilitres of *water,* requires for neutralisation not less than 26.6 or more than 27.1 millilitres of *N/1 solution of sulphuric acid, solution of methyl orange* being used as indicator. Yields no characteristic *reactions* for copper, iron, aluminium, zinc, magnesium, or chlorides, and not more than the slightest *reactions* for calcium or sulphates. *Lead limit* 10 parts per million. *Arsenic limit* 5 parts per million." *Br.*

"**Assay.**—Dissolve about 1.5 Gm. of Lithium Carbonate, previously dried to constant weight at 100° C. and accurately weighed, in 50 cc. of normal sulphuric acid and titrate the solution with normal potassium hydroxide, methyl orange T.S. being used as indicator. Each cc. of normal sulphuric acid corresponds to 0.03694 Gm. of Li_2CO_3. Each Gm. of Lithium Carbonate, previously dried, corresponds to not less than 26.7 cc. of normal sulphuric acid." *N. F.*

F. A. Flückiger states that lithium carbonate is less soluble in warm water than in cold water.

He recommends as a test of purity that it should require for solution 70 parts or a little more of water at 15° C. and states further that its solution saturated at 90° C. has the sp. gr. 1.009 at 15° C.; this latter solution contains 1 part of the salt in 111.3 parts of water. (*A. Pharm.*, 1887, p. 509.)

Effervescing Lithium Carbonate may be made as follows: Take of citric acid, 40 parts, sodium bicarbonate, 50 parts, and lithium carbonate, 10 parts. Powder and mix well, then introduce into a wide flat-bottomed dish, and heat to about 100° C., stirring constantly until the powder becomes granular. Separate the granules of uniform size by means of appropriate sieves, and preserve them in well-stoppered bottles. (See *Lithii Citras Effervescens.*)

Uses.—In 1843 Alexander Uré called attention to the fact that uric acid was comparatively freely soluble in solutions of lithium carbonate. This observation was confirmed by Garrod in 1857 who recommended the use of the metal in both acute and chronic forms of gout. This recommendation has been blindly followed by a large proportion of the medical profession for more than fifty years without questioning the validity of the scientific basis and without any close analysis of the clinical results. Garrod's experiment, however, as pointed out by H. C. Wood, Jr. (*J. A. M. A.*, 1916, lxvi, p. 1069), involved conditions which are absolutely inapplicable to human medicine; as a matter of fact it has been shown that the addition of lithium carbonate even in fatally large doses does not affect the solubility of sodium urate in the blood. Moreover there is no convincing clinical evidence of the usefulness of lithia in *gout*.

The clinical results which have been achieved with the "Lithia Waters" have been due to the water in them and not to the lithium. Of a large number of natural "Lithia Waters" examined by the Bureau of Chemistry of the U. S. Department of Agriculture, none contained more than one twentieth grain per gallon, while most of them contain only spectroscopic traces.

In sufficient quantities lithium acts upon the system very much like potassium, being depressant to the nerve centers and to the circulation. The non-toxic salts of lithium, like those of potassium, have a diuretic effect, and if given in sufficient dose may aid in the elimination of various substances from the blood, and incidentally the poisons of *gout*, but are probably not superior to the potash salts. Lithium carbonate has the properties of the other earthy carbonates but, being less soluble than the sodium and potassium salts, is perhaps somewhat less prone to irritate the stomach.

Dose, five to fifteen grains (0.32–1.0 Gm.).

Off. Prep.—Sal Potassii Bromidi Effervescens Compositum, *N. F.*

LITHII CITRAS. N. F., Br.

LITHIUM CITRATE Lith. Cit.

"Lithium Citrate contains not less than 98.5 per cent. of $Li_3C_6H_5O_7.4H_2O$ (281.95)." *N. F.*

"Lithium Citrate may be obtained by the interaction of citric acid and lithium carbonate. It contains not less than 98.5 per cent. of pure lithium citrate, $Li_3C_6H_5O_7,4H_2O$." *Br.*

Lithiæ Citras, Lithium Citricum; Citrate of Lithium, Citrate of Lithia; Citrate de Lithine, *Fr.;* Citronensaures Lithium, Lithiumcitrat, *G.;*

Description and Physical Properties.—"Lithium Citrate occurs as a white powder, or in the granular form; odorless and having a cooling, faintly alkaline taste. It is deliquescent on exposure to moist air and loses its water of crystallization when heated to 150° C. One Gm. of Lithium Citrate dissolves in 1.4 cc. of water at 25° C.; very slightly soluble in alcohol.

"An aqueous solution of the salt (1 in 20) is faintly alkaline to litmus but is not reddened by one drop of phenolphthalein T.S. At a red heat the salt chars, emits inflammable vapors having a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame. Boil an aqueous solution of Lithium Citrate (1 in 20) with an equal volume of calcium chloride T.S.; a white precipitate forms.

"Treat the residue obtained by igniting 0.4 Gm. of the salt at a red heat with a slight excess of diluted hydrochloric acid, filter, wash the residue with distilled water, evaporate the filtrate and washings almost to dryness on a water bath, in a flat-bottomed flask of 50 cc. capacity, add 10 cc. of amyl alcohol and cautiously heat the mixture until the lower aqueous layer has evaporated. Then add 3 drops of hydrochloric acid and boil the solution for three minutes. The resulting insoluble residue, if any, when collected on a filter, washed with amyl alcohol and dried at 110° C., weighs not more than 0.004 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. An aqueous solution of the salt does not respond to the Test for heavy metals.

"**Assay.**—Proceed as directed under the Assay for alkali salts of organic acids. Each cc. of half-normal sulphuric acid corresponds to 0.04699 Gm. of $Li_3C_6H_5O_7.4H_2O$. Each Gm. of Lithium Citrate corresponds to not less than 21 cc. of half-normal sulphuric acid.

"Preserve it in air-tight containers." *N. F.*

Lithium citrate is described by the Br. as: "Small white crystals. Taste saline, cooling. Soluble in 2 parts of *water*. Yields the *reactions* characteristic of citrates. Heated to redness it blackens, evolving inflammable gases; and the residue, neutralised with *hydrochloric acid*, yields with *alcohol* (90 per cent.) a solution which burns with a crimson flame. 1

gramme, heated to redness till gases cease to be evolved, leaves an alkaline residue which, when treated with *water,* filtered, and well washed, yields a clear solution requiring for neutralisation not less than 10.5 millilitres of *N/1 solution of sulphuric acid. Lead limit* 5 parts per million. *Arsenic limit* 2 parts per million. Free from the impurities indicated under 'Lithii Carbonas.'" *Br.*

It is somewhat deliquescent in moist, and efflorescent in dry, air. It usually shows a feebly alkaline reaction with litmus.

Uses.—Lithium citrate, like the corresponding salts of sodium and potassium, is oxidized in the system and appears in the urine as a carbonate. It may be used for precisely the same purposes as the other citrates, but has no real advantage. It is the compound which is employed in making the widely used so-called "lithia tablets."

Dose, from ten to thirty grains (0.65–2.0 Gm.).

Off. Prep.—Lithii Citras Effervescens, *Br.;* Sal Lithii Citras Effervescens, *N. F.*

LITHII CITRAS EFFERVESCENS. Br.

EFFERVESCENT LITHIUM CITRATE

Limonade sèche au Citrate de Lithine, *Fr.;* Brauselithiumcitrat, *G.*

"Sodium Bicarbonate, in Powder, 580 *grammes;* Tartaric Acid, in powder, 310 *grammes;* Citric Acid, in powder, 210 *grammes;* Lithium Citrate, in powder, 50 *grammes.* Mix the Lithium Citrate with the Citric Acid, then add the Tartaric Acid, and, lastly, the Sodium Bicarbonate, triturating thoroughly. Place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it, by means of suitable sieves, into granules of uniform and convenient size. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand *grammes.*" *Br.*

A similar preparation is in the N. F. (see *Sal Lithii Citratis Effervescens,* Part III).

Uses.—This effervescent salt forms an agreeable method of administering lithia; its medicinal properties are those of lithium citrate.

Dose, two drachms (7.7 Gm.), given in solution.

LITHII SALICYLAS. N. F.

LITHIUM SALICYLATE Lith. Salicyl.

"Lithium Salicylate contains, when dried to constant weight at 120° C., not less than 98.5 per cent. of $LiC_7H_5O_3$ (144.02)." *N. F.*

Salicylate de Lithine, *Fr.;* Lithium Salicylicum, *P. G.;* Lithiumsalicylat, *G.;* Salicilato de Litina, *Sp.*

No process is given in the N. F. for making this official salt. It may be prepared by adding to a mixture of eleven parts of salicylic acid and three parts of lithium carbonate, twenty-five parts of water, and heating until effercescence ceases, filtering and evaporating. It may be obtained in crystals but is usually seen in the form of a granular powder.

Description and Physical Properties.—"Lithium Salicylate occurs as a white or grayish white powder; deliquescent in a moist atmosphere; odorless, taste sweetish. It is very soluble in water and in alcohol.

"When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame. An aqueous solution of the salt (1 in 20) is neutral or slightly acid to litmus, and when freshly made is colorless (*iron and organic coloring matter*); it does not effervesce upon the addition of diluted acids (*carbonate*). Copper sulphate T.S. added to an aqueous solution of the salt (1 in 20) produces a bright green color. Add a few drops of ferric chloride T.S. to an excess of an aqueous solution of the salt (1 in 4); a deep red color is produced. In a dilute solution of the salt (1 in 100) ferric chloride T.S. produces a deep violet-blue color. Hydrochloric acid added to an aqueous solution of the salt (1 in 20) produces a voluminous white precipitate of salicylic acid. Dissolve 0.7 Gm. of the salt in 10 cc. of distilled water, add an excess of hydrochloric acid and filter. Evaporate the filtrate almost to dryness on a water bath, in a 50 cc. Erlenmeyer flask, and then add 10 cc. of amyl alcohol and cautiously heat until the lower aqueous layer is evaporated; then add three drops of hydrochloric acid and boil the liquid for three minutes; the insoluble residue weighs not more than 0.005 Gm. (*other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. Dissolve 1 Gm. of the salt in 50 cc. of distilled water, precipitate the salicylic acid by the addition of a slight excess of hydrochloric acid and filter; the filtrate does not respond to the Test for heavy metals.

"**Assay.**—Weigh accurately 1 Gm. of Lithium Salicylate which has been previously dried for 24 hours over sulphuric acid, mix it with 2 Gm. of powdered ammonium sulphate in a porcelain crucible and cautiously ignite it. The weight of the residue of lithium sulphate multiplied by 2.629 represents it equivalent in Lithium Salicylate.

"Preserve it in well-closed containers, protected from heat." *N. F.*

The proportion of lithium in this salt is too small to sensibly modify the action of the salicylic acid. It may be used for the same purposes as the other salicylates.

Dose, ten to twenty grains (0.6–1.3 Gm.).

Off. Prep.—Elixir Hydrangeæ et Lithii, *N. F.;* Elixir Manacæ Compositum, *N. F.*

LOBELIA. U. S., Br.

LOBELIA Lobel.

"Lobelia consists of the dried leaves and tops of *Lobelia inflata* Linné (Fam. *Lobeliaceæ*). Lobelia contains not more than 10 per cent. of stems or more than 2 per cent. of other foreign organic matter, and yields not more than 5 per cent. of acid-insoluble ash." *U. S.* "Lobelia is the dried flowering herb of Lobelia inflata, *Linn.*" *Br.*

[1] Indian or Wild Tobacco, Asthma-weed, Puke-weed, Gag-root, Vomitwort, Bladder Pod, Eyebright; Lobélie enflée, *Fr.;* Herba Lobeliæ, *P. G.;* Lobelienkraut, *G.;* Lobelia, *It.*

Lobelia inflata is an annual or biennial plant common in roadsides and neglected fields throughout the Eastern United States and Canada, usually a foot or more in height, with a fibrous root, and a solitary erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, or alternate, petiolate, the upper sessile, ovate, or oblong, about two inches (5 cm.) long, irregularly toothed, pubescent, pale green. The flowers are numerous, small, disposed in leafy terminal, axillary racemes. The calyx is five-toothed and much inflated in fruit. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, oblong, reticulated brown seeds. Most of the commercial supplies of the drug come from Massachusetts, Michigan and New York.

All parts of it are medicinal, but, according to Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. The German Pharmacopœia directs that Lobelia should be gathered at the end of the flowering period. A number of the foreign Pharmacopœias do not permit the inclusion of the fruit. The drug of commerce ofttimes is collected late in the season after most of the leaves have fallen and the plant has gone to seed. At times the commercial drug consists of the entire herb, and again may consist chiefly of the thick and inert stems. It may be kept whole or in powder. As found in commerce, it is often in oblong compressed cakes, prepared by the Shakers or the herb dealers. It has been suggested that in cultivating *Lobelia inflata* the seeds should be planted in the autumn. (*Ann. Rep. U. S. Dept. Agric.*, 1905, p. 147.)

Dried lobelia has a slightly irritating color, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended in like manner with a flow of saliva and a nauseating effect.

Description and Physical Properties.—"*Unground Lobelia.*—Leaves alternate, sessile or narrowing into a short petiole, usually more or less broken; when entire, blades ovate or oblong from 2 to 9 cm. in length, obtusely toothed or irregularly serrate-denticulate, each tooth with a yellow-brown, gland-like apex; pale green and with scattered bristly hairs; stem cylindrical, coarsely and irregularly furrowed, yellowish-green, occasionally purplish and with numerous spreading hairs; flowers pale blue, in a long, loose raceme with short pedicels, calyx tubes ovoid, with 5 subulate teeth, corollas tubular, from 3 to 4 mm. in length, 5-parted, the upper 2-lobed portion cleft nearly to the base; stamens with anthers united above into a curved tube enclosing the bifid stigma; capsule ovoid or ellipsoidal, from 5 to 8 mm. in length, light brown, wholly inferior and enclosing numerous brownish, oblong and coarsely reticulate seeds; odor slight and irritating; taste strongly acrid.

"*Powdered Lobelia.*—Dark green; fragments of seed-coat composed of more or less polygonal cells with thick, yellowish walls; occasional non-glandular hairs, elongated-conical, from 0.30 to 1.11 mm. in length; fragments of stem with tracheæ showing annular or spiral thickenings or simple pores associated with narrow wood-fibers, the walls of the latter being rather thin, more or less lignified and porous; fragments of epidermis of leaf with elliptical stomata, up to 0.035 mm. in length, and usually with 3 or 4 neighboring cells; pollen grains nearly spherical, from 0.020 to 0.030 mm. in diameter." *U. S.*

"Stems angular, channelled, and furnished with narrow wings; often of a purplish tint; bearing one-celled hairs and the scars of alternate leaves. Leaves irregularly toothed and hairy. Capsules inflated, two-celled, containing when ripe, minute, oblong, reticulated, brown seeds. In transverse section of the stem, laticiferous vessels in the bast. Somewhat irritating odor; taste at first not marked, but subsequently burning and acrid. Ash not more than 12 per cent." *Br.*

The morphology of *Lobelia inflata* is described and illustrated by Holm in *Merck's Rep.*, xvi, p. 341.

Constituents.—The activity of lobelia depends on the presence of a liquid alkaloid first isolated by Procter in 1838 and by him named *lobeline.*

Ordinarily lobeline is a yellowish liquid, lighter than water, of a somewhat aromatic odor, and a very persistent, acrid taste, but when absolutely pure is odorless and colorless. It is sparingly soluble in water, but much more copiously in alcohol and ether, and the latter fluid readily removes it from its aqueous solution. It has an alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and hydrochloric acids, and a very soluble, but not crystallizable salt, with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely evaporated, but the salts it forms with acids are not volatile. Siebert (*In. Dis.*, Marburg, 1891) from a study of the crystallized hydrochloride and chloroplatinate, derived the formula $C_{18}H_{23}O_2N$ for the free alkaloid. Wieland (*B. Chem. G.*, 1921, liv, 1784) has found a second alkaloid *lobelidine*. This is crystalline and has the formula $C_{20}H_{25}O_2N$. He also reported the presence of a third alkaloid, to which, however, he gave no definite name. A British patent granted to Böhringer describes three alkaloids: *alpha-lobeline,* $C_{21}H_{23}O_2N$, crystalline; *beta-lobeline,* amorphous and *gamma-lobeline,* also amorphous (see *D. C.*, 1921, lxv, 102).

Pereira found a peculiar acid which he named *lobelic acid;* besides gum, resin, chlorophyl, fixed oil, lignin, salts of lime and potassium, with ferric oxide. Enders' *lobelacrin,* according to Lewis (*P. J.*, 1878, viii), is a mixture of lobeline lobelate, with lobelic acid. Lloyd has isolated a crystalline neutral principle (*Ph. Rund.*, 1887, 32) which melts at 225° C., to which he gave the name *inflatin.* It does not appear to have any therapeutic value. According to Procter the seeds contain a much higher percentage of lobeline than the rest of the plant; from the whole plant he obtained a yield of one-fifth of one per cent. The alkaloid appears to be a rather unstable body, being decomposed by boiling temperature as well as by the caustic alkalies.

Vanderkleed and E'we (*Proc. P. P. A.*, 1916, p. 276) propose a method for assaying this drug and its preparations.

Uses.—Lobelia is said to have been used as a medicine by the aborigines of America, but was first brought into general professional notice by Cutler, of Massachusetts. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. When toxic doses are taken, these symptoms are very severe, and have added to them burning pain in the fauces or esophagus, progressive failure of voluntary motion, rapid, feeble pulse, fall of temperature, and finally collapse with stupor or coma; in some cases convulsions precede death. Death has often resulted from its empirical use. Its poisonous effects are most likely to occur when, as sometimes happens, it is not rejected by vomiting.

In large quantities lobelia has a paralyzant effect on the peripheral motor nerves like that of curare, but this action plays little rôle in its therapeutic usefulness. Edmunds (*A. J. Phys.*, 1904, xi, p. 80) finds that the chief effect is upon the sympathetic ganglia like nicotine, first stimulating and secondarily depressing. During the primary stage of stimulation there is increased flow of saliva, dilation of the pupil, constriction of the blood vessels, slowing of the pulse, and other evidences of sympathetic excitation. The slowing of the pulse at first more than counterbalances the vascular constriction, and the blood pressure is usually lowered; later, however, the pulse becomes very rapid and the blood pressure high. The vomiting appears to be due to an action upon the emetic center. In the secondary stage of poisoning the pupil is contracted, salivary secretion checked, respirations slow, and the blood pressure falls. Wieland and Mayer (*A. E. P. P.*, 1922, xcii, 195) state that pure lobeline does not excite either the emetic center nor the sympathetic ganglia, nor does it have any marked action on the vagus; they find its chief action is as a respiratory stimulant. These results are, in a measure, confirmed by the work of Behrens and Pulewka (*B. K. W.*, 1924, iii, 1677) who report a beneficial action on the respiration in poisoning by carbon monoxide. According to Muto and Iwakawa (*A. E. P. P.*, 1910, lxii), lobeline is a primary stimulant to the respiratory center, the failure in respiration which occurs after toxic doses being due to its paralytic effect on the phrenic nerve. According to Dixon and Brodie (*J. P.*, 1903, xxix), it causes a relaxation of the bronchial muscles which may, however, be preceded by a short stage of constriction.

As an emetic lobelia should never be employed. Its most important use in medicine is as a nauseating expectorant in *bronchitis,* especially when associated with bronchial spasm. Large doses will sometimes cause complete cessation of the *asthmatic* paroxysms, but it is more commonly employed between the paroxysms for its combined expectorant and antispasmodic influence.

By the eclectics lobelia is used in a host of convulsive and inflammatory disorders, including *epilepsy, tetanus, diphtheria,* and *tonsillitis.*

The tincture affords the most eligible mode of administration; in asthmatic cases it may be given in doses of fifteen minims (0.9 cc.) every hour until an effect is produced. Numes (*T. G.*, 1889) asserts that he has used lobeline in a number of cases of *asthma* with most excellent results in doses of from three-fourths of a grain to six grains a day; but it can scarcely be doubted that he had a very impure alkaloid, and that such doses of a pure sample would be highly dangerous. There is on the market a preparation stated to be alpha-lobeline which is recommended as a respiratory stimulant in doses of one-twentieth to one-sixth of a grain (0.003–0.01 Gm.).

Dose, of lobelia, one to five grains (0.06–0.3 Gm.).

Off. Prep.—Tinctura Lobeliæ, *U. S.;* Tinctura Lobeliæ Ætherea, *Br.;* Fluidextractum Lobeliæ, *N. F.*

LOTIO HYDRARGYRI FLAVA. Br.

YELLOW MERCURIAL LOTION

Aqua Phagedænica Flava; Yellow Wash, Yellow Lotion; Eau phagédénique, Eau divine de Fernel, Phagédénique, *Fr.;* Phagedänisches Wasser, Altschadenwasser, *G.*

"Mercuric Chloride, 4.6 *grammes;* Solution of Lime, 1000.0 *millilitres.* Mix." *Br.*

This lotion is about 11 per cent. stronger than that official in the Br. Ph., 1885. A similar preparation, but differing in strength, is official in the N. F. (See *Lotio Flava,* Part III.)

The reaction between the mercuric chloride and the calcium hydroxide in this preparation results in the precipitation of the yellow mercuric oxide in a hydrated form and in a very finely divided condition. It is used as a soothing and antiseptic application in *scrofulous* or *syphilitic ulcers;* it has been especially recommended in scrofulous *conjunctivitis.*

LOTIO HYDRARGYRI NIGRA. Br.

BLACK MERCURIAL LOTION

Aqua Phagedænica Nigra; Aqua Nigra, Aqua Mercurialis Nigra; Black Wash, Black Lotion; Eau Phagédénique noire, *Fr.;* Schwarzes Wasser, *G.*

"Mercurous Chloride, 6.85 *grammes;* Glycerin, 50.00 *millilitres;* Solution of Lime, sufficient to produce 1000.00 *millilitres.* Triturate the Mercurous Chloride with the Glycerin and gradually add sufficient Solution of Lime to produce the required volume." *Br.*

The addition of glycerin improves this lotion by aiding in the suspension of the insoluble powder. By the reaction between the calomel and calcium is formed the black mercurous oxide. This lotion has medical properties very similar to those of the yellow wash. It has also been recommended by Shoemaker in *ivy poisoning.* A similar preparation is official in the N. F. IV. (See *Lotio Nigra,* Part III.)

LOTIONES.

LOTIONS

Washes; Lotions, *Fr.;* Waschungen, *G.*

This class has been introduced into the British Pharmacopœia in order to give official recognition to two preparations, the *black wash* or *lotio nigra,* and the *yellow wash,* or *lotio flava,* which have long been in use, and which will be found above.

LUPULINUM. N. F.

LUPULIN

"Lupulin consists of the glandular trichomes separated from the strobiles of *Humulus Lupulus* Linné (Fam. *Moraceæ*). Lupulin yields not less than 60 per cent. of ether-soluble extractive and not more than 10 per cent. of acid-insoluble ash." *N. F.*

Lupulinic Glands; Lupulin, *Fr. Cod.;* Lupulite, *Fr.;* Glandulæ Lupuli, Hopfenmehl, Lupulin, *G.;* Luppolino, *It.;* Lupulino, *Sp.*

The collective fruit of the hop known as "strobile" (see *Humulus*) consists of leafy stipules and bracts at the base of which are the minute fruits. Scattered over the fruit and the neighboring portions of the bract are numerous yellowish brown glands. These may be separated by agitation of the strobiles. These separated granules are the glandular trichomes recognized under the name of *lupulin.* To a considerable extent they are shaken free in the ordinary handling of hops and much of the commercial lupulin is obtained by sifting the sweepings from the floor of hop kilns, and therefore contains much extraneous matter like sand and dirt of various kinds.

Description and Physical Properties.—"A bright yellowish-brown, granular powder, having the characteristic odor and taste of hops. Glandular trichomes somewhat globular or ellipsoidal, from 0.1 to 0.3 mm. in diameter, consisting of a single layer of secreting cells assuming the form of a shallow cup, from the inner surface of which the cuticle has been separated by the secreted yellowish brown oleo-resin.

"Preserve Lupulin in tightly closed containers, protected from the light. Lupulin which has become a dark reddish color and developed a disagreeable and valerian-like odor due to aging must not be used.

"**Assay.**—Proceed as directed under ether-soluble extractive." *N. F.*

It is inflammable, and when moderately heated becomes somewhat adhesive.

Lupulin consists of an ether-soluble portion of considerably over half the weight of the lupulin, the predominating constituent in this portion being *beta resin* and a *beta acid,* similar to those referred to under hops. An alpha resin and an alpha acid are also present, and a gamma resin and a fatty oil. The ether-soluble portion contains the inorganic constituents: albuminoids, pentosans, crude fiber, tannin, etc. Lecithin has been reported in some samples of lupulin and also minute traces of an alkaloid. The odor of lupulinic grains resides in the essential oil. This is obtained to the extent of 0.9 per cent. by distilling hops with water. When distilled from the fresh strobiles the oil has a greenish color, but a reddish-brown when old hops have been employed. It is devoid of rotatory power, neutral to litmus paper, and gives no remarkable coloration with concentrated sulphuric acid. According to Chapman (*J. Chem. S.,* 1895, liv, 780), the essential oil consists of two terpenes. one $C_{10}H_{16}$, and the other $C_{10}H_{18}$, boiling between 160° and 171° C. and a sesquiterpene called *humulene,* boiling at 263° to 266° C. This latter makes up almost two-thirds of the oil. There is also a small amount of an oxygenated constituent, probably $C_{10}H_{18}O$.

Lupulin is supposed to possess the therapeutic properties of hops. (See *Humulus.*)

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Fluidextractum Lupulini, *N. F.*

LYCOPODIUM. U. S.

LYCOPODIUM Lycopod.

"Lycopodium consists of the spores of *Lycopodium clavatum* Linné (Fam. *Lycopodiaceæ*)." *U. S.*

Club Moss, Stag's horn, Semen Lycopodii, Pulvis Lycopodii, Sulphur Vegetabile; Vegetable Sulphur; Lycopode, *Fr. Cod.;* Soufre végétal, *Fr.;* Lycopodium, *P. G.;* Bärlappsamen, Streupulver, Hexenmehl, Blitzpulver, *G.;* Licopodio, *It.*, *Sp.*

Lycopodium clavatum, commonly called *club moss,* has a trailing, branching stem, several feet long, and thickly beset with linear-awl-shaped, flat, ribless, smooth leaves, tipped with a fine bristle, curved upward, and of a light green color. The fructification is in terminal spikes, single or in pairs, with crowded ovate, entire, pointed scales, bearing in the axil a transversely oval sporangium which splits nearly to the base and contains the narrow reticulate spores. The plant is a native of Europe, Asia, and America, being especially common in the dry woods northward. The spores are collected in the Ukraine, Poland, Switzerland and Germany. Most of the drug of commerce is now gathered in Poland and the Ukraine. It is shipped to this country in bags and cases from Danzig, Hamburg and London.

Description and Physical Properties.—"A light, yellow, very mobile powder, odorless and tasteless; the spores shaped as a three-sided pyramid with convex base, from 0.025 to 0.040 mm. in diamter; the outer surface reticulate, the reticulations being polygonal and formed by straight-sided delicate ridges, which form a delicate fringe at the edge of the spore; when viewed with the rounded surface of the spore on the under side, a distinct triangular marking is seen, formed by the edges of the flat surfaces of the spore.

"Lycopodium is not wetted by water but floats upon it; when boiled with water, it sinks. When Lycopodium is thrown into a flame, it burns with a quick flash. Lycopodium shows very few, if any, pollen grains from 0.040 to 0.070 mm. in diameter, and consisting of a central, convex, generative cell separating two spherical cells or wings containing air (*pine pollen*). Lycopodium boiled with water and cooled does not give a bluish or reddish color with iodine T.S. (*starch or dextrin*)." *U. S.*

Lycopodium is composed of nearly 50 per cent. of fatty oil, from 3 to 6 per cent. of nitrogen, as albuminous principles, and considerable carbohydrate material. The ash, which ranges from 3 to 5 per cent., is about half P_2O_5. The fatty oil is mainly olein although there is present small amounts of phytosterin, and traces of the glycerides of arachitic, palmitic and stearic acids. A distinctive acid, lycopodic acid, has been reported to the extent of about 2 per cent. in the oil. The *lycopodic acid* crystallizes in silky needles, it is doubly refracting like quartz, and appears to be isomeric with dioxystearic acid. (*D. C.*, 1891, 155; see also *A. Pharm.*, 1908, 246.) Stenhouse found volatile bases to be present in very small amount. Lycopodium is frequently adulterated with such substances as slightly roasted and colored starch, dextrine, powdered colophony, talc, various pollens and a number of other substances. All of these may be readily detected by the microscope. The pollen of coniferous trees has been sold in Austria under the name of *Lycopodium Hungaricum.*

Folleto recommends two reactions to detect pollen: one by adding to a syrupy solution of zinc chloride, potassium iodide and iodine to saturation; the pollen is colored yellow by this reagent, lycopodium is not colored; the other reagent is methyl-green, which colors pollen green, but does not color lycopodium. (*Ph. Centralh.*, 1896, 527.)

Uses.—Lycopodium was formerly used as an absorbent application to *excoriated surfaces,* but has been largely replaced by other dusting powders. Its chief employment is in pharmacy for the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The club moss itself (under the titles of *Herba Lycopodii* or *Herba Musci Clavati*) has been esteemed diuretic and antispasmodic; its decoction has been employed in *rheumatism, diseases of the lungs and kidneys,* but it has fallen into complete desuetude. One of the ingenious uses for lycopodium in microscopy is to mix a little of it with an unknown powder or on a slide on which a mount is made. The spores are easily recognizable and distinguishable from other elements and give an excellent idea of the approximate size of the elements which are being observed, as the spores are almost uniformly 40 microns in size.

MAGMA MAGNESIÆ. U. S.

MAGNESIA MAGMA Magma. Mag. [Milk of Magnesia]

"Magnesia Magma yields not less than 6.5 per cent. nor more than 7 per cent. of $Mg(OH)_2$." *U. S.*

"Magnesium Sulphate, 300 Gm.; Sodium Hydroxide, 100 Gm.; Distilled Water, a sufficient quantity to make about 1000 cc.

"Dissolve the magnesium sulphate in sufficient distilled water to make 650 cc., place this in a vessel of about 5000 cc. capacity, and heat to boiling. Dissolve the sodium hydroxide in sufficient distilled water to make 1000 cc., add this slowly to the boiling solution of magnesium sulphate, and continue the boiling for thirty minutes. Transfer the mixture to a cylindrical container of not less than 5000 cc. capacity, and fill with hot distilled water. Allow to stand until separation has occurred, and remove the supernatant liquid. Wash repeatedly with hot distilled water until sulphates have practically been eliminated, as shown by testing the supernatant liquid with barium chloride T.S. Concentrate the mixture by evaporation until it contains not less than 7 per cent. of magnesium hydroxide. Note—one-half cc. of oil of peppermint, or a sufficient quantity of oil of anise or other suitable flavoring may be added if desired." *U. S.*

Many suggested improvements for the preparation of milk of magnesia have appeared in the pharmaceutical literature during recent years. Bertha Mueller (*A. J. P.*, 1920, xcii, 162) makes the preparation by hydrating light magnesium oxide under specified conditions. R. W. Terry (*J. A. Ph. A.*, 1919, viii; 1920, ix, 148) in a most exhaustive research upon the subject makes a number of specific recommendations based upon analysis of numerous market samples and many experiments in preparing the product.

The present official formula differs from that of the U. S. IX, which was based on a reaction between magnesium carbonate and sodium hydroxide suggested by McNeary (*J. A. Ph. A.*, 1916, p. 611). For other formulas see *U. S. D.*, 20th ed., p. 671.

Description and Physical Properties.—"A viscous, opaque, white mixture, from which more or less water usually separates on standing; free from mustiness.

"It is alkaline to litmus paper and to phenolphthalein T.S.

"A solution of 2 cc. of diluted hydrochloric acid and 1 cc. of Magnesia Magma responds to the reactions for magnesium.

"The addition of 2 cc. of diluted hydrochloric acid to 1 cc. of Magnesia Magma causes not more than a slight effervescence (*carbonate*), and the resulting solution is not more than slightly turbid. Dilute 20 cc. of Magnesia Magma with distilled water to make 200 cc., and allow it to stand until the precipitate has settled. Remove 50 cc. of the clear liquid, and evaporate it to dryness on a water bath. The residue, when dried to constant weight at 150° C., does not exceed 0.005 Gm. To another 50 cc. portion of the supernatant liquid, add 1 drop of methyl orange T.S., and titrate with tenth-normal sulphuric acid: not more than 0.4 cc. is required to produce a red color (*soluble alkalies*).

"Preserve in wide-mouthed bottles, tightly stoppered with corks which have been dipped in melting paraffin.

"**Assay.**—Place about 5 Gm. of Magnesia Magma in a tared flask, stopper, and weigh accurately, add 25 cc. of normal sulphuric acid, and after solution is complete titrate the excess of acid with normal sodium hydroxide, using methyl orange T.S. as indicator. Each cc. of normal sulphuric acid corresponds to 0.02917 Gm. of $Mg(OH)_2$." *U. S.*

The incompatibilities of milk of magnesia are, in general, those of magnesium oxide. It should be remembered that this suspension is due to the colloidal condition of the magnesium hydroxide which is likely to be disturbed by various salts.

Magma magnesia, popularly known as *milk of magnesia*, is an excellent and convenient alkali, useful as an antacid and mild laxative in *hyperacidity of the stomach*, whether due to *hypochlorhydria* or *fermentative dyspepsia*, and is useful for the other purposes for which magnesium oxide is used. One drachm is equivalent to approximately four grains of magnesium oxide. Milk of magnesia is also widely employed as a mouth-wash, and especially for the correction of acid conditions of the mouth. For this purpose the addition of a trace of some aromatic oil, such as peppermint or anise, is a great advantage.

Dose, one to four fluidrachms (3.75–15 cc.).

MAGNESII CARBONAS. U. S. (Br.)

MAGNESIUM CARBONATE Mag. Carb.

"Magnesium Carbonate is a mixture of hydrated magnesium carbonate and magnesium hydroxide, corresponding to not less than 39.2 per cent. of MgO." *U. S.*

Magnesii Carbonas Levis, Light Magnesium Carbonate, *Br.;* **Magnesii Carbonas Ponderosus**, Heavy Magnesium Carbonate, *Br.;* Magnesia Hydrico-carbonica, Carbonas Magnesicus, Magnesia Alba, Magnesiæ Carbonas, Carbonate of Magnesia; Magnesii Hydrocarbonicum, *Fr. Cod.;* Magnésie blanche, *Fr.;* Magnesium carbonicum, *P. G.;* Magnesiumcarbonat, Kohlensaure Magnesia, Weisse Magnesia, *G.;* Idrocarbonato di Magnesio, Carbonato di Magnesia, *It.;* Carbonato Magnesico, Magnesia blanca, *Sp.*

This corresponds nearly with "Magnesii Carbonas Levis" of the British Pharmacopœia. A Heavy Magnesium Carbonate is also official in the British Pharmacopœia.

Magnesium is a white, very brilliant metal, of sp. gr. 1.75, resembling silver, malleable, fusible at a low temperature, and convertible into magnesium oxide by the combined action of air and moisture. It burns with great facility, and affords by its combustion a light which is intensely white and very rich in actinic, or chemically active, rays, so that it finds wide application in signal lights and for photography. Many of the so-called "flash powders" contain metallic magnesium in a finely divided state as their basis. With nitric and hydrochloric acids magnesium forms salts which are soluble in either water or alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydroxide, and by potassium and sodium carbonates as a carbonate, but it is not precipitated by the alkaline bicarbonates, nor by ammonium carbonate.

Magnesium carbonate sometimes occurs as a native mineral known as *magnesite*, the best deposits of which are those of the Grecian Archipelago, though a common variety is found in Chester Co., Pa., and a large deposit has been discovered in Clark Co., Nevada. That which is sold in commerce is prepared on a large scale by the manufacturer. In the British Pharmacopœia directions are given for preparing it in two forms. The following are the directions:

1. MAGNESII CARBONAS LEVIS. *Light Magnesium Carbonate*, Br.—"Light Magnesium Carbonate is a hydrated magnesium oxycarbonate obtained by the following process:—Magnesium

Sulphate, 125 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, *a sufficient quantity.* Dissolve the Magnesium Sulphate and the Sodium Carbonate separately, each in one thousand *millilitres* of cold Distilled Water; mix the solutions; boil the mixture for fifteen minutes; transfer the precipitate to a calico filter; wash it with boiling Distilled Water until the washings are free from sulphates, and dry at a temperature not exceeding 100° C." *Br.*

The resulting carbonate is characterized in the British Pharmacopœia as "a very light, white powder, which, when examined under the microscope, is found to consist of amorphous particles with numerous slender prisms intermixed. It otherwise possesses the general characters and responds to the tests described under 'Magnesii Carbonas Ponderosus.'" *Br.*

2. MAGNESII CARBONAS PONDEROSUS. *Heavy Magnesium Carbonate,* Br.—"Heavy Magnesium Carbonate is a hydrated magnesium oxycarbonate obtained by the following process: —Magnesium Sulphate, 125 *grammes;* Sodium Carbonate, 150 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve the Magnesium Sulphate and the Sodium Carbonate separately, each in two hundred and fifty *millilitres* of the Distilled Water; mix the solutions, and evaporate to dryness; digest the residue for half an hour with five hundred *millilitres* of the Distilled Water; collect the insoluble matter on a calico filter, wash with the Distilled Water until the washings are freed from sulphates, and dry at a temperature not exceeding 100° C." *Br.*

This is essentially the old process of the Dublin College, and yields a product which is characterized in the British Pharmacopœia as "a white granular powder. Readily soluble with effervescence, in the diluted mineral acids, the solutions yielding the *reactions* characteristic of magnesium. Loses from 56 to 58 per cent. of its weight when heated to redness. Yields no characteristic *reactions* for aluminium, copper, or calcium, and not more than the slightest *reactions* for iron, chlorides, or sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million." *Br.*

The following method is said to be pursued by some of the best manufacturers. To a saturated solution of 100 parts of magnesium sulphate, a solution of 125 parts of crystallized sodium carbonate is gradually added, the solutions being constantly stirred. The mixture is heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with barium salts. When sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it a square and compact form. Pattinson's process is the one chiefly used by the larger manufacturers. It depends upon the fact that, on treating calcined dolomite, in the presence of water, with carbon dioxide under pressure, the magnesia dissolves as bicarbonate before any of the accompanying lime enters in solution. The calcined and finely powdered mineral is introduced, together with water, into a cylinder with a horizontal axis, and, while it is being kept in constant motion by a stirring apparatus, carbon dioxide, under a pressure of five to six atmospheres, is forced into it. The resulting solution of magnesium bicarbonate, which is perfectly free from lime, if the process has been properly managed, is then transferred to a vertical cylinder, where it is heated with steam, whereby magnesium carbonate is separated, which is collected, formed into prismatic pieces, and dried. The carbon dioxide required issues from the earth immediately outside of the factory, and the dolomite is furnished by the quarries of May and Urban, near Dietz and Steelen on the Lahn. (*A. Pharm.*, Aug., 1880; *N. R.*, Sept., 1881.) When made from bittern, magnesium carbonate is contaminated with calcium carbonate, salts of lime being contained in sea water, and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided is to prepare pure magnesium sulphate by repeated crystallization, and to use a pure sodium carbonate. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia. Kippenberger prepares crystallized magnesium carbonate by shaking *freshly* precipitated magnesium carbonate with a solution of potassium bicarbonate at the ordinary temperature; much of the magnesium carbonate dissolves and crystallizes out of the filtered solution upon standing for a day. Sodium bicarbonate may be used instead of the potassium salt, but the crystals are smaller. (*Zeit. Anorg. Chem.*, 1894, 177.) J. G. Ferrier criticized the processes for making the carbonates by the British Pharmacopœia; he stated that there was a conspicuous want of uniformity in the results obtained. (*P. J.*, 1904, 586.)

The density of magnesium carbonate is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch upon the use of sodium carbonate in its preparation. Much of the magnesium carbonate formerly used in this country was imported from England and Ireland, but that now consumed in the United States is chiefly a home product. The composition of magnesium carbonate and its physical condition are exhaustively discussed by Broeksmit (*Ph. Wb.*, 1921, lviii, 210) who points out that a crystalline $MgCO_3.3H_2O$ occurs on standing.

The formula given by the British Pharmacopœia of 1898 is $3MgCO_3 + Mg(OH)_2 + 4H_2O$; in other words, a combination of three molecules of magnesium carbonate, one of magnesium hydroxide, and four of water. While the U. S. Pharmacopœia gives no formula in the text it is written in the molecular weight tables as follows: "Basic (approximately) $(MgCO_3)_4Mg(OH)_2 + 5H_2O$." The composition of this salt varies with the mode of preparation.

Description and Physical Properties.—"Light, white, friable masses, or a bulky, white powder. It is odorless, and is stable in the air. Magnesium Carbonate is practically insoluble in water, to which, however, it imparts a slightly alkaline reaction. It is insoluble in alcohol, but is dissolved by dilute acids with effervescence. When strongly heated, it loses water and carbon dioxide, and is converted into magnesium oxide.

"When Magnesium Carbonate is treated with diluted hydrochloric acid, it dissolves with effervescence and the resulting solution responds to the reactions for magnesium.

"Mix 1 Gm. of Magnesium Carbonate with 50 cc. of distilled water, heat the mixture to the boiling point, and cool. Then filter, and evaporate the filtrate to dryness on a water bath. The weight of the residue does not exceed 0.01 Gm. (*soluble salts*). Dissolve 2.5 Gm. of Magnesium Carbonate in 50 cc. of diluted hydrochloric acid and 200 cc. of distilled water: the solution is colorless. Transfer 50 cc. of this solution to a 50 cc. graduated cylinder and add 0.2 cc. of potassium ferrocyanide T.S. After mixing well, the color produced in the solution, if any, when viewed downward against a white surface is not greater than the color of a control solution prepared as follows: Dilute 0.2 cc. of ferric chloride T.S. with sufficient distilled water to make 1000 cc. Transfer 25 cc. of this solution to another 50 cc. graduated cylinder, and add 10 cc. of diluted hydrochloric acid and sufficient distilled water to make 50 cc. Then add 0.2 cc. of potassium ferrocyanide T.S. The two cylinders used in this test must be matched, be of practically colorless glass and have the same internal diameter (*iron*). Dissolve 0.5 Gm. of Magnesium Carbonate in a slight excess of diluted hydrochloric acid (about 5 cc.), and dilute with distilled water to 25 cc.: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals*. Dissolve 4 Gm. of Magnesium Carbonate in 50 cc. of diluted hydrochloric acid in a beaker of about 900 cc. capacity. Dilute this solution to about 400 cc. with distilled water, add 5 Gm. of ammonium chloride, heat to boiling, and add 50 cc. of ammonium oxalate T.S., followed by 5 drops of methyl orange T.S., and afterwards by ammonia T.S. (previously diluted with two volumes of distilled water), added slowly in small portions, stirring constantly until the liquid has assumed a yellow color. This operation normally requires about twenty minutes. Allow the liquid to stand for four hours or over night, collect the precipitate on a filter, wash it with hot, distilled water containing 1 per cent. of ammonium oxalate solution, until the washings, after strongly acidifying with nitric acid, cease to react with silver nitrate T.S. Dissolve the precipitate by pouring 50 cc. of warm diluted hydrochloric acid in small portions over the filter, wash the filter with about 100 cc. of distilled water, collect the solution of the precipitate and washings in the same beaker, then dilute to 400 cc. with distilled water, and reprecipitate as before (omitting the addition of 5 Gm. of ammonium chloride). Allow the new precipitate to stand four hours or over night, filter, and wash as before, then dry the precipitate within the filter paper and after cautious ignition in a platinum crucible, heat the residue until of constant weight. The heat should be applied gently at first, the temperature should then be gradually increased, and finally the heat of a blast lamp should be applied for fifteen minutes or longer if necessary. Cool the crucible and contents in a desiccator before weighing. The weight of CaO so obtained does not exceed 0.032 Gm., corresponding to not more than 0.8 per cent (*limit of calcium oxide*).

"**Assay.**—Dissolve about 1 Gm. of Magnesium Carbonate, accurately weighed, in 30 cc. of normal sulphuric acid, and determine the residual acid by titrating with normal sodium hydroxide, using methyl orange T.S. as indicator. From the volume of the normal sulphuric acid consumed, deduct the volume of normal sulphuric acid corresponding to the per cent of calcium oxide found. The difference represents the normal sulphuric acid equivalent to the magnesium oxide present. Each cc. of normal sulphuric acid corresponds to 0.02016 Gm. of MgO or to 0.02804 Gm. of CaO." *U. S.*

A solution in carbonic acid water, prepared by passing carbon dioxide into a reservoir containing magnesium carbonate suspended in water, has been introduced into use as a cathartic and antacid. *Dinneford's Magnesia* is a solution of this nature and contains the dissolved magnesia in the form of bicarbonate into which the carbonate is converted by the carbon dioxide under pressure. According to Christison, it contains only nine grains of carbonate in the fluidounce, though alleged to contain twice that quantity. Its taste is more disagreeable than that of the undissolved carbonate. A formula for this preparation has been introduced into the British Pharmacopœia, with the name of *Liquor Magnesii Bicarbonatis.*

An investigation of the properties of magnesium carbonate as a clarifying and filtering agent was made by one of the Fellows of the Mellon Institute of Industrial Research (*Am. Drug.*, 1921, lxix, p. 24). The clarifying value was stated to be due to the great absorbent powers of this compound. General recommendations for its use in this connection were made without any warning of the injury that would result to preparations affected by alkalies.

It has long been recognized in pharmacy that magnesium carbonate has very limited uses in this connection because of the neutralizing power upon acids, the precipitating effect upon alkaloids, and the fact that aqueous solutions become slightly alkaline. For this reason it was abandoned many years ago as a filtering medium in the preparation of the official aromatic waters.

Uses.—Magnesium carbonate is antacid, and, by combining with acid in the stomach, usually acts as a cathartic. When it undergoes no change in the alimentary canal it produces no purgative effect. Under these circumstances it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid, and, though prone to produce flatulence in consequence of the liberation of its carbon dioxide in the stomach and bowels, and therefore, in ordinary cases, inferior to calcined magnesia, it sometimes operates favorably, in consequence of this very property, in *sick stomach* attended with acidity. As an antacid, it has the advantages over sodium carbonate of being less irritating and of neutralizing a larger proportion of acid. It is best administered in water or milk. In order that it may be uniformly diffused through water, it should be previously rubbed up with syrup or ginger syrup.

Dose, as an antacid, five to twenty grains (0.32–1.3 Gm.); as a laxative, one-half to two drachms (2–7.7 Gm.).

MAGNESII CHLORIDUM. N. F.

MAGNESIUM CHLORIDE Magnes. Chlorid.

"Magnesium Chloride contains, when dried for twenty-four hours over sulphuric acid, not less than 95 per cent. of $MgCl_2.6H_2O$ (203.34)." *N. F.*

Description and Physical Properties.—"Magnesium Chloride occurs as colorless, transparent crystals, or as white, translucent pieces; deliquescent in moist air. One Gm. dissolves in about 0.6 cc. of water; it is readily soluble in alcohol. The aqueous solution of the salt (1 in 20) is neutral to litmus paper.

"An aqueous solution of the salt, acidulated with nitric acid yields a white precipitate upon the addition of silver nitrate T.S. A mixture of 10 cc. of an aqueous solution of the salt (1 in 20) with 10 cc. of ammonium chloride T.S., rendered slightly alkaline with ammonia water, yields a white precipitate on the addition of sodium phosphate T.S.

"One Gm. of the salt dissolves in 10 cc. of alcohol, leaving not more than 1 per cent. of insoluble residue (*substances insoluble in alcohol*). Add 3 cc. of potassium sulphate T.S. to 10 cc. of an aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid; no turbidity results (*barium*). Ten cc. of an aqueous solution of the salt (1 in 200), acidulated with hydrochloric acid, is not reddened by potassium thiocyanate T.S. (*iron*). Warm 5 cc. of an aqueous solution of the salt (1 in 10) with 10 cc. of sodium hydroxide T.S.; the odor of ammonia is not evolved. A mixture of 10 cc. of an aqueous solution of the salt (1 in 20), 10 cc. of ammonium chloride T.S. and 5 cc. of ammonia water, is not rendered more than slightly turbid upon the addition of ammonium oxalate T.S. (*calcium*). An aqueous solution of the salt does not respond to the Test for heavy metals. An aqueous solution of the salt meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 0.5 Gm. of Magnesium Chloride previously dried to constant weight over sulphuric acid and accurately weighed, in 50 cc. of distilled water in a 200 cc. measuring flask; add 3 cc. of nitric acid, then add 50 cc. of tenth-normal silver nitrate and sufficient distilled water to make the mixture measure 200 cc. Mix thoroughly, filter through a dry filter, reject the first 20 cc. of filtrate, then collect 100 cc. of filtrate, add 2 cc. of ferric ammonium sulphate T.S. and titrate the excess of silver nitrate with tenth-normal potassium thiocyanate. Each cc. of tenth-normal silver nitrate used, corresponds to 0.010167 Gm. of $MgCl_2.6H_2O$. Each Gm. of Magnesium Chloride corresponds to not less than 93.4 cc. of tenth-normal silver nitrate." *N. F.*

Chilbret (*R. P.*, 1910, p. 646) has revived the use of this salt as a laxative, and believes it superior to either the sulphate or citrate, but its advantage seems very questionable. Being deliquescent, it is necessary to give it in solution.

Dose, from one to four drachms (3.75–15 Gm.).

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.*

MAGNESII OXIDUM. U. S. (Br.)

MAGNESIUM OXIDE Mag. Oxid. [Magnesia, Light Magnesia]

"Magnesium Oxide contains, after ignition, not less than 96 per cent. of MgO. Upon ignition it loses not more than 10 per cent." *U. S.* "Light Magnesia, MgO, is prepared by exposing Light Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Levis, *Br.;* Calcined Magnesia; Oxydum Magnesii, Oxide of Magnesia, Magnesia Calcinata; Magnésie calcinée, Magnésie, *Fr.;* Magnesii Oxydatum, *Fr. Cod.;* Magnesia Usta, *P. G.;* Gebrannte Magnesia, *G.;* Ossido di magnesio, *It.;* Oxido magnesico, *Sp.*

In the British Pharmacopœia, 1885, directions were given for preparing two forms of magnesia, one called *Magnesia Levis,* or *Light Magnesia,* from the light carbonate, and the other *Magnesia Ponderosa,* from the heavy carbonate. It is the former which corresponds with our ordinary magnesia. Neither Pharmacopœia gives a detailed process. "Take of Light Carbonate of Magnesium, *four ounces.* Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the center of the crucible, cooled, moistened with water, and dropped into warm diluted sulphuric acid, causes no effervescence." *Br.*, 1885.

By exposure to a red heat, the water and carbon dioxide of the magnesium carbonate are expelled, and the oxide remains. Taking the accepted formula for the carbonate as the starting point, the reaction is as follows:

$$(MgCO_3)_4 + Mg(OH)_2 + 5H_2O = 5MgO + 6H_2O + 4CO_2$$

About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbon dioxide. (Duncan.) A more certain indication, however, is the absence of effervescence when hydrochloric acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbon dioxide, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine.

Many processes have been proposed for manufacturing *light calcined magnesia* as it was formerly called. These will be found in *U. S. D.*, 20th ed., p. 674.

The sp. gr. of magnesium oxide is commonly stated at 2.3. It was deemed infusible until melted by means of the oxyhydrogen blowpipe of Hare. When sufficiently heated, it conducts electricity and shines with an intense light, which fact is utilized in the Nernst lamp. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature, producing thereby the hydroxide $Mg(OH)_2$. It is almost insoluble, requiring, according to Fyfe, 5142 parts of water at 15.5° C., and 36,000 parts of boiling water, for solution.

Description and Physical Properties.—"A white, very bulky, odorless powder. On exposure to air, it absorbs moisture and carbon dioxide.

"Magnesium Oxide is practically insoluble in water and is insoluble in alcohol. It is dissolved by dilute acids.

"A solution of Magnesium Oxide in diluted hydrochloric acid responds to the reactions for magnesium.

"Boil 1 Gm. of Magnesium Oxide with 50 cc. of distilled water, cool, and filter: the filtrate is not more than faintly alkaline to litmus paper, and when evaporated to dryness leaves not more than 0.02 Gm. of residue (*soluble salts*). Boil a mixture of 0.1 Gm. of Magnesium Oxide with 5 cc. of distilled water, and after cooling pour it into 5 cc. of acetic acid: solution takes place without the evolution of more than a few isolated gas bubbles (*carbonate*). It meets the requirements of the test for *iron* under *Magnesii Carbonas*, using 1 Gm. of Magnesium Oxide. Dissolve 0.5 Gm. of Magnesium Oxide in a slight excess of diluted hydrochloric acid, and dilute with distilled water to 25 cc.: a 10 cc. portion of this solution meets the requirements of the test for *heavy metals*. Transfer to a porcelain crucible about 1 Gm. of Magnesium Oxide, weigh accurately, and expose to a low red heat (about 600° C.), it loses not more than 10 per cent. of its weight (*water and other volatile substances*). When determined by the method described under *Magnesii Carbonas*, using about 1.5 Gm. of freshly ignited Magnesium Oxide, accurately weighed, it shows not more than 2 per cent. of calcium oxide.

"Preserve in well-closed containers." *U. S.*

"A white powder differing only from 'Magnesia Ponderosa' in its bulk, the volumes corresponding to the same weight having the ratio of three and a half to one." *Br.*

"**Assay.**—Ignite about 0.5 Gm. of Magnesium Oxide to constant weight at a low red heat, weigh the residue accurately, dissolve it in 30 cc. of normal sulphuric acid, and determine the residual acid by titrating with normal sodium hydroxide, using methyl orange T.S. as indicator. From the volume of the normal sulphuric acid consumed, deduct the volume of normal sulphuric acid corresponding to the per cent. of calcium oxide found. The difference represents the normal sulphuric acid equivalent to the magnesium oxide present. Each cc. of normal sulphuric acid corresponds to 0.02016 Gm. of MgO or to 0.02804 Gm. of CaO." *U. S.*

Magnesia is liable to contain, as impurities, magnesium carbonate, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. Lime is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste. According to Wittstein, calcium oxalate is soluble in the neutral salts of magnesium, requiring 50 parts of magnesium chloride, and 90 of magnesium sulphate, and consequently there might be no precipitate, or one redissolved by the liquid, should the proportion of lime be very small. (*J. P. C.*, 4e sér., iii, 216.) On this account a special method of determining small amounts of calcium salts has been introduced into the texts of magnesium oxide and magnesium carbonate of the U. S. P.

Uses.—Magnesium oxide is used in medicine chiefly for its antacid properties. In cases of *gastric hyperacidity*, whether due to overactivity of the acid-secreting glands of the stomach or to fermentative changes in the foodstuff, it is one of the best correctives that we have. It has the advantages over bicarbonate of soda that it is less irritating to the mucous membrane, that it does not evolve any gas, and that the dose required is smaller. One grain of magnesium oxide has about the same neutralizing power as four grains of sodium bicarbonate. When given in large enough dose it exercises a laxative effect. This aperient action is due to the union of the magnesium with the acids of the primæ viæ. When it meets with no acid, it is apt to linger in the stomach or bowels, and should in that case be followed by lemonade. It may be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydroxide. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. In this connection Duncan recommends boiling the magnesia for a few moments with half the quantity of water prescribed to prevent subsequent caking. It has been conjectured that anhydrous magnesia might prove injurious to the stomach by solidifying its liquid contents, and the oxide which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated magnesium hydroxide will serve as an antidote to arsenic trioxide, though less efficient than ferric hydroxide. The experiments of Carles have shown that the soluble *magnesium saccharate* is not superior as an antidote for arsenic to simple magnesia. Ohleyer (*L. L.*, July, 1873) employs magnesia as a dressing in *ulcers* and *abrasions,* while Vergley recommends for *burns* calcined magnesia triturated with milk so as to form a paste, which should be applied thickly several times a day.

Dose, as an antacid, five to twenty grains (0.32–1.3 Gm.); as a laxative, one-half to one drachm (2–3.9 Gm.).

Off. Prep.—Ferri Hydroxidum cum Magnesii Oxido, *U. S.;* Pulvis Rhei Compositus, *Br.*

MAGNESII OXIDUM PONDEROSUM. U. S. (Br.)

HEAVY MAGNESIUM OXIDE Mag. Oxid. Pond. [Heavy Magnesia]

"Heavy Magnesium Oxide contains, after ignition, not less than 96 per cent. of MgO. Upon ignition it loses not more than 10 per cent." *U. S.* "Heavy Magnesia, MgO, is prepared by exposing Heavy Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Ponderosa, *Br.;* Heavy Calcined Magnesia; Oxide of Magnesium; Magnésie Calcinée pesante, *Fr.;* Schwere Gebrannte Magnesia, *G.*

This was directed, in the British Pharmacopœia, 1885, to be prepared precisely in the same manner as light magnesia, using, however, the heavy carbonate (Heavy Magnesium Carbonate, *Br.*).

Description and Physical Properties.—"A white, dense, odorless and very fine powder, which meets the requirements of the tests for identity, purity, and the Assay under *Magnesii Oxidum.* Preserve in well-closed containers." *U. S.* It is described by the Br. Ph., as "a white powder, insoluble in *water,* but readily dissolved by acids, the solution yielding the *reactions* characteristic of magnesium. Yields no characteristic *reactions* for aluminium and copper, and not more than the slightest *reactions* for iron, calcium, carbonates, and sulphates. *Lead limit* 20 parts per million. *Arsenic limit* 5 parts per million. Loses not more than 1 per cent. of its weight when heated to dull redness." *Br.*

The two varieties of light and heavy magnesia differ only in their weight in the same bulk, the volumes corresponding to the same weight being to each other in the ratio of three and one-half to one. (See *Magnesii Oxidum.*)

Dose, five to sixty grains (0.32–3.9 Gm.).

Off. Prep.—Pulvis Rhei et Magnesiæ Anisatus, *N. F.*

MAGNESII SULPHAS. U. S., Br.

MAGNESIUM SULPHATE Mag. Sulph. [Epsom Salt]

"Magnesium Sulphate contains not less than 48.60 per cent. and not more than 53.45 per cent. of $MgSO_4$, corresponding to not less than 99.5 per cent. of the crystallized salt [$MgSO_4.7H_2O$]." *U. S.* "Magnesium Sulphate may be obtained by the interaction of the native magnesium carbonates and diluted sulphuric acid; or by purifying the native sulphate. It contains not less than 97.4 per cent. of pure magnesium sulphate, $MgSO_4,7H_2O$." *Br.*

Sal Amarum, Sal Epsomense, Sal Anglicum, Sal Sedlicense, Sulphas Magnesicus; Sulphate of Magnesia; Sulfate de Magnésie, *Fr. Cod.;* Sel d'Epsom, Sel de Sedlitz, Sel. amer, *Fr.;* Magnesium Sulfuricum, *P. G.;* Magnesiumsulfat, Schwefelsaures Magnesia, Bittersalz, *G.;* Solfato di magnesio, Sulfato magnesico, *Sp.*

Magnesium Sulphate is a constituent of sea water, and of some saline springs. It also occurs native, either crystallized in slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils which contain magnesia and a sulphate or sulphide. In the United States it is found in the great caves so numerous to the west of the Allegheny Mountains. In one of these caves, near Corydon in Indiana, it formed a stratum on the bottom several inches deep, or appeared in masses sometimes weighing ten pounds, or disseminated in the earth of the cavern, one bushel of which yielded from four to twenty-five pounds of the sulphate. It also appeared on the walls of the cavern, and, if it was removed, acicular crystals again appeared in a few weeks. (Cleveland.) An enormous deposit has been reported at Basque, British Columbia.

Under the name of *kieserite,* a mineral is obtained from the saline deposits at Stassfurt, in Germany, which consists chiefly of impure magnesium sulphate. It is used as a source for preparing magnesium sulphate, and is exported from Germany; for a historical paper on Epsom salt by M. I. Wilbert, see *Proc. A. Ph. A.,* 1904, 351.

Magnesium sulphate was originally procured by evaporating the waters of saline springs at Epsom, in England. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea water furnished by careful evaporation precisely the same salt, and, as this was a much cheaper product, it superseded the former for a time. At present, in the neighborhood of Genoa and Nice, magnesium sulphate is prepared in large quantities from a schistose rock containing magnesia and iron sulphide. The mineral is roasted, and exposed in heaps for some months to the action of air and water. It is then lixiviated, the ferrous sulphate decomposed by lime water, and the salt obtained pure by repeated solution and crystallization. It is also extensively manufactured in Baltimore and Philadelphia from a silicious magnesium hydroxide. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighborhood of Baltimore and in the southern counties of Pennsylvania. The mineral is reduced to a fine powder and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert any ferrous sulphate which may be present into ferric oxide. It is then dissolved in water, and calcium sulphide added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared by this process is generally very pure and clean, although it sometimes contains a trace of ferrous sulphate. A very pure magnesium sulphate free from chloride is obtained as a by-product in the manufacture of carbon dioxide from magnesite when sulphuric acid is used to decompose the carbonate. This industry at one time assumed large proportions because of the demand for liquefied carbon dioxide in the manufacture of aerated and effervescing mineral waters. In the modern method of making carbon dioxide, however, acid is not used, the CO_2 being evolved by simply heating the magnesite (magnesium carbonate) to a little over 300° C. Magnesium sulphate is also obtained from *kieserite* and *kainite* from the Stassfurt mines, Germany. There are deposits of native magnesium sulphate, *epsomite,* in Wyoming, Utah, Washington and California. *Dolomite* (a native magnesio-calcium carbonate) is also used for the manufacture of magnesium sulphate, calcium sulphate being obtained as a by-product.

Description and Physical Properties.—"Small, colorless, prismatic needles or rhombic prisms, without odor, and having a cooling, saline, and bitter taste. One Gm. of Magnesium Sulphate is soluble in 1.3 cc. of water and in about 1.1 cc. of glycerin, at 25° C. One Gm. is soluble in about 0.2 cc. of boiling water. It is sparingly soluble in alcohol at 25° C. When exposed to warm air, the salt loses some of its water of crystallization and is converted into a white powder. Further heating removes more water, and at a temperature somewhat above 200° C. it is rendered anhydrous.

"An aqueous solution of the salt (1 in 20) responds to the reactions for magnesium and for sulphates. An aqueous solution of the salt (1 in 20) is neutral to litmus paper.

"One Gm. of the salt shows no more *chloride* than corresponds to 0.2 cc. of fiftieth-normal hydrochloric acid. An aqueous solution of the salt meets the requirements of the test for *heavy metals.* An aqueous solution of the salt meets the requirements of the test for *arsenic.*

"Preserve in well-closed containers." *U. S.*

"In small, colorless, transparent, rhombic prisms. Taste bitter. Soluble in 1 part of *water.* Yields the *reactions* characteristic of magnesium and of sulphates. When 0.5 gramme is dissolved in 50 millilitres of *water,* and to the solution 20 millilitres of *solution of ammonium chloride,* 20 millilitres of *strong solution of ammonia,* and excess of *solution of sodium phosphate* are added in succession, the mixture, after well stirring and setting aside for twelve hours, yields a precipitate which, when collected, washed with *strong solution of ammonia* diluted with three times its volume of *water,* dried and heated to redness, weighs not less than 0.220 and not more than 0.226 gramme. Yields no characteristic *reactions* for zinc, and not more than the slightest *reactions* for chlorides. *Lead limit* 5 parts per million. *Arsenic limit* 5 parts per million. 10 grammes dissolved in 20 millilitres of *water,* and heated on a water-bath for one hour in a closed flask, yield a clear, colorless solution (absence of insoluble impurities and of more than traces of iron)." *Br.*

Assay.—"Dissolve about 1 Gm. of Magnesium Sulphate, accurately weighed in 100 cc. of distilled water, gradually add to the solution, with constant stirring, an excess of sodium phosphate T.S. (about 20 cc.), allow the mixture to stand for ten minutes, then add 30 cc. of ammonia T.S., and let stand for four hours. Collect the precipitate on a filter, wash it with dilute ammonia T.S. (1 volume of ammonia T.S. to 19 volumes of distilled water) until the washings are free from sulphates. Dry, and ignite to constant weight. The weight of magnesium pyrophosphate ($Mg_2P_2O_7$) when multiplied by 1.081 indicates its equivalent in $MgSO_4$. Each Gm. of Magnesium Sulphate corresponds to not less than 0.4495 Gm. and not more than 0.4944 Gm. of magnesium pyrophosphate ($Mg_2P_2O_7$)." *U. S.*

It usually occurs in small acicular crystals, which are produced by agitating the solution while crystallizing. It slowly effloresces in the air. Exsiccated magnesium sulphate is employed in some localities under the title *Magnesium Sulphuricum Siccum.* It is a fine white powder of which about 65 parts represents 100 parts of the crystallized salt.

Magnesium sulphate is completely decomposed by potassium and sodium hydroxides and their carbonates, by lime, barium and strontium oxides, and their soluble salts. Ammonia partially decomposes it, and forms with the remainder a double sulphate. Potassium and sodium bicarbonates do not decompose it, except by the aid of heat. An economic use which has been recommended of magnesium sulphate is the addition of a strong solution to ordinary white-wash, whereby a beautiful whiteness may be given to walls and ceilings. A little of it, moreover, added to starch considerably increases its stiffening properties, and at the same time in some degree resists the action of fire.

Uses.—Magnesium sulphate is an active cathartic operating with but little pain or nausea, and producing watery stools. Its cathartic action is due in part to its attraction for water, but it seems also to exercise a direct stimulant effect upon the glands of the intestinal tract. It has but little direct effect upon peristalsis, the increased movements of the intestinal muscles being due chiefly to the over distention with the fluid. It may be used whenever it is desired to clean out the alimentary canal, especially when a prompt action is desired, as in cases of *poisoning* or certain types of *acute enteritis.* It is a valuable remedy when it is desired to encourage the elimination of metabolic poisons through the bowel, as in *gout* or *uremia.* It is also highly esteemed for the evacuation of *dropsical effusions.* As an habitual laxative, although widely used, it is generally inferior to the vegetable cathartics.

When injected into the circulation magnesium sulphate acts as a violent poison, lessening respiration and depressing the circulation by a direct action upon the heart. It also paralyzes the peripheral ends of the motor nerves and, according to Meltzer and Auer (*A. J. Phys.,* 1905, xiv, p. 366, and xvii, p. 313), also the sensory nerves. Guthrie and Ryan (*A. J. Phys.,* 1910, xxiv, p. 329) dispute the conclusions of Meltzer and Auer that it has a true anesthetic action, believing that the apparent anesthesia is due to the motor paralysis, but the experiments of Wiki (*A. I. P. T.,* 1911, xxi, p. 415) seem to demonstrate that when applied locally it is a paralyzant to the sensory nerves. As an internal remedy it has been employed by intraspinal injection as an anesthetic and in the treatment of *tetanus.* Its action in tetanus appears to be solely that of an anticonvulsant, not a true curative, and whether it has any superiority over other methods of controlling the convulsions is at present uncertain. As an antitetanic fifteen to thirty grains (1–2 Gm.) may be injected daily into the subarachnoid space in 10 per cent. solution. For intraspinal anesthesia, although it has been used with apparent success in a few cases, it appears to have no advantage over the cocaine series and has shown itself distinctly irritant to the kidney.

As a local remedy magnesium sulphate has proven useful in a large number of inflammatory conditions, its value probably to be attributed to its osmotic influence. Because of the fact that it does not diffuse readily, it attracts more water to itself than other salts. Not only is it widely employed as a local dressing in *sprains* and *bruises,* but Tucker (*T. G.,* 1907) and a number of subsequent investigators as Freese (*N. Y. M. J.,* Feb. 14, 1914) have reported favorable results in *erysipelas, cellulitis, epididymitis, lymphangitis* and similar external inflammations. Meltzer (*J. P. Ex. T.,* 1918, xii), from experiments upon rabbits as well as in observations on human beings, found a 25 per cent. solution to be of great value in the treatment of *burns* of both first and second degree. Morrison and Tulloch (*Brit. Journ. Surgery,* Oct., 1915, p. 276) have even recommended the local use of a sterilized solution of magnesium sulphate in septic wounds.

Following the suggestion of Meltzer that the intraduodenal application of magnesium sulphate produced a relaxation of the sphincter of the common bile duct, Lyon (*J. A. M. A.,* 1919, lxxii, p. 980) applied the drug by means of a duodenal tube in the diagnosis and treatment of *cholecystitis.* While the method has been more or less favorably commented on by several writers, Frazer (*J. A. M. A.,* 1922, lxxix, p. 1594) in experiments upon dogs was unable to note any constant action upon the flow of bile either from the liver or gall bladder.

As Christison reported the case of a boy ten years old who was said to have been killed by two ounces of the salt without the induction of purgation, it is possible that, under some circumstances, when very large amounts of magnesium sulphate are given by the mouth, sufficient may be absorbed to produce poisonous effects.

Dose, one to eight drachms (3.9–31 Gm.).

Off. Prep.—Infusum Sennæ Compositum, *U. S.;* Magnesii Sulphas Effervescens, *N. F., Br.;* Mistura Sennæ Composita, *Br.;* Liquor Magnesii Sulphatis Effervescens, *N. F.;* Sal Kissingense Factitium Effervescens, *N. F.;* Sal Vichyanum Factitium, *N. F.;* Sal Vichyanum Factitium Effervescens, *N. F.*

MAGNESII SULPHAS EFFERVESCENS. Br.

EFFERVESCENT MAGNESIUM SULPHATE

Magnesium Sulphuricum Effervescens; Magnesiæ Sulphas Effervescens; Effervescent Sulphate of Magnesia; Effervescent Epsom Salt; Brausendes Magnesiumsulfat, *G.;* Sulfato magnesico effervescente, *Sp.*

"Magnesium Sulphate, in crystals, 500 *grammes;* Sodium Bicarbonate, in powder, 360 *grammes;* Tartaric Acid, in powder, 190 *grammes;* Citric Acid, in powder, 125 *grammes;* Refined Sugar, in powder, 105 *grammes.* Dry the Magnesium Sulphate at about 55° C. until it has lost twenty-three per cent. of its weight; powder the dried product; mix it with the Refined Sugar and then with the other ingredients. Place the mixture in a dish or pan of suitable form heated to between 90° and 105° C. When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 55° C. The product weighs about one thousand *grammes.*" *Br.*

This effervescent salt is intended to furnish a less disagreeable form of administering Epsom salt. Although it represents only 50 per cent. of magnesium sulphate, it is almost equally active, both the sodium tartrate and citrate which are formed being laxative. A similar preparation is recognized by the N. F. (see Part III).

Dose, from two drachms to one ounce (7.7–31 Gm.).

MALTUM. U. S.

MALT

"Malt is the grain of one or more varieties of *Hordeum sativum* Jessen (Fam. *Gramineæ*), partially germinated artificially, and containing amylolytic enzymes." *U. S.*

Maltum Hordei; Barley Malt; Malt d'Orge, *Fr.;* Gerstenmalz, Malz, *G.*

Preparation.—Malt is prepared on an enormous scale for brewing purposes in many parts of the world where the climate is suited to the growth of barley. The object of the process for making malt, commonly known as malting, is to allow germination of grain to go just far enough to develop the maximum amount of diastase, the ferment by which the starch is converted into sugar, which may afterwards undergo the alcoholic fermentation during the process of brewing. In order to achieve this, the barley is first "steeped"—*i.e.,* allowed to remain one or two days in cold water, of which it absorbs from 10 to 50 per cent.; second, "couched"—*i.e.,* thrown into heaps upon a floor and allowed to develop heat and germinate; third, when the acrospire or shoot is one-third the length of the grain, the latter is "floored"—*i.e.,* spread upon wide floors to dry; fourth, kiln-dried—*i.e.,* exposed to such a temperature as thoroughly to dry it and kill the young plant. If the temperature be raised high enough to scorch the grain, it becomes *Amber Malt,* or *Black Malt,* according to the extent of the caramelizing; only the light colored varieties of malt are suitable for pharmaceutical purposes, the black varieties being practically devoid of diastatic value and being used for coloring mainly. Besides the diastase, a second soluble ferment is formed during the malting process, the so-called *peptase,* which in the after-mash process changes the proteids of the malt into peptones and para-peptones which give nutritive value to the beer. Malt contains the alkaloid *hordenine.* (See under *Hordeum,* Part II.)

Malt is now frequently germinated by what is called the pneumatic system in which the operation is carried out in large perforated iron drums which are caused to revolve very slowly, and in which the temperature is carefully regulated by ventilating fans. Another mechanical system of malting which is extensively used in some countries, especially in France, is based upon the principle of the ordinary conveyer, a separate section being used for each day that the germination lasts.

The commercial value of a sample of malt is determined by its diastatic power and also by its content of aqueous extract estimated under specified conditions. Between one-half and three-fourths of malt is soluble in cold water.

It is composed of germinated grains with the radicles and acrospires adhering.

Description and Physical Properties.—"Yellowish or amber-colored grains. Malt is crisp when broken, the interior surface being nearly white. It has an agreeable, characteristic odor and a sweet taste, due to the conversion of the starch of the seed into maltose through the action of the diastase. Malt floats on cold water. For the subsequent tests prepare an infusion as follows: Mix 10 Gm. of Malt, in coarse powder, with 100 cc. of distilled water, and maintain the mixture at a temperature of from 50° to 55° C. for one hour, occasionally stirring. Place it upon a filter, and, when the liquid has passed through, wash the contents of the filter with distilled water, in small portions, until the combined infusion and washings measure 200 cc.

"The weight of the solid soluble constituents of Malt, obtained by evaporating to dryness on a water bath an aliquot portion of the freshly prepared, aqueous infusion and drying the residue for one hour at 100° C., is not less than 70 per cent. of the Malt taken. The acidity of Malt, determined by titrating an aliquot portion of the freshly prepared infusion with tenth-normal sodium hydroxide, using phenolphthalein T.S. as indicator does not exceed 0.3 per cent. calculated as lactic acid.

"Preserve protected from heat and moisture." *U. S.*

Uses.—Malt is not itself used directly in medicine, but is official as the basis of Extract of Malt. From it are also prepared the so-called *Malt Liquors* by making an infusion (*wort*) of the bruised malt, adding hops and various other substances, and fermenting. *Ale, brown stout,* and *porter* are made by rapid fermentation at a comparatively high temperature 23.8 C., while *lager beer* is prepared by a very slow, prolonged fermentation at a low temperature.

Off. Prep.—Extractum Malti, *U. S.*

MALVÆ FOLIA. N. F.

MALLOW LEAVES Malv. Fol.

"Mallow Leaves consist of the dried leaves of *Malva sylvestris* Linné and of *Malva rotundifolia* Linné (Fam. *Malvaceæ*). Mallow Leaves contain not more than 10 per cent. of other parts of plants yielding the drug and not more than 5 per cent. of foreign organic matter." *N. F.*

Malva sylvestris; Mallow; Folia Malvæ, *P. G.;* High Mallow; Cheese-Cake Flower, Pancake Plant; Pick-Cheese, Maul, Round Dock.

M. rotundifolia: Low Mallow, Running Mallow, Dutch Cheese, Doll Cheese, Pellas.

The National Formulary recognizes two species of mallow. The *Malva sylvestris,* or high mallow, is an erect biennial herb with more or less sharply five- to seven-lobed leaves and reddish-purple flowers. The *M. rotundifolia,* common mallow, has an annual or biennial procumbent stem, and orbicular obscurely lobed leaves and pale blue flowers. The common term of "cheeses" is applied to these plants because of the peculiar shape of the fruit. These are circular, flattish, berry-like capsules consisting of numerous carpels united in a ring around a central axis from which they separate after ripening. Both of these species are natives of Europe and Western Asia, but have been more or less naturalized in the United States. The high mallow, however, is not very common in this country. The leaves often show brownish spots due to a fungous growth; when so infected they should not be used.

The commercial supplies of this drug are imported from Hamburg, Leghorn, Budapest and London. The drug is shipped in bales.

Description and Physical Properties.—"*Unground Mallow Leaves.*—Leaves of *Malva sylvestris,* petiolate with petioles up to 10 cm. in length, orbicular or reniform, slightly truncate or cordate at the base, from 10 to 11 cm. in length, and from 15 to 20 cm. in width, with 3 to 7 shallow, angular or rounded lobes, venation palmate, margins crenate-dentate, pubescent on both sides. Leaves of *Malva rotundifolia,* with petioles up to 20 cm. in length, orbicular, up to 8 cm. in width, base deeply cordate, 5 to 7 shallow lobes, venation palmate, margins with rounded blunt teeth, pubescence more scant than in *M. sylvestris.* Intermixed with the leaves are frequently found dark purple flowers and glabrous reticulated carpels (*M. sylvestris*) or pale bluish flowers and pubescent rounded carpels (*M. rotundifolia*). Inodorous; on chewing it becomes very mucilaginous, taste bland.

"*Structure.*—Epidermis containing mucilage cells; numerous stomata on both surfaces, each with 3 or 4 neighboring cells; trichomes of 3 distinct types, small short-stalked glandular hairs, single, large, one-celled curved hairs with thick walls and compound or stellate hairs in groups of 2 to 6 cells (the latter especially numerous in *M. sylvestris*); palisade tissue of 1 to 2 rows of cells, the spongy parenchyma of 3 or 4 rows; the parenchyma containing calcium oxalate in rosette crystals and numerous mucilage cells which are distributed in the tissue of the veins; veins with collateral bundles.

"*Powdered Mallow Leaves.*—Light green; exhibits the characteristic hairs, the single non-glandular hairs up to 1 mm. in length, occasionally longer, fragments of epidermal tissue with stomata, the latter up to 0.038 mm. in length; fragments of pith parenchyma, fibers and tracheæ from the stems; mucilage cells, fragments of spongy parenchyma and palisade, containing many branching vascular bundles, the tracheæ with spiral annular or reticulate markings; rosette crystals of calcium oxalate up to 0.025 mm. in diameter." *N. F.*

The herb and flowers have a weak, herbaceous, mucilaginous taste, without odor. They abound in mucilage, which they readily impart to water, and the solution is precipitated by lead acetate. The infusion and tincture of the flowers are blue, and have been used as indicators, being reddened by the acids and rendered green by alkalies. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent.

The infusion and decoction are sometimes employed in *catarrh, dysentery,* and *nephritis complaints,* and are applicable to all other cases which call for the use of mucilaginous liquids.

Off. Prep.—Species Emollientes, *N. F.*

MANACA. N. F.

MANACA Manac.

"Manaca is the dried root of *Brunfelsia Hopeana* Benth (*Franciscea uniflora* Pohl.) (Fam. *Solanaceæ*)." *N. F.*

Manacan, Vegetable Mercury, Geratacáca, Camgániba, Mercurio vegetal.

Brunfelsia Hopeana Benth. (*Franciscea Hopeana* Hook.; *F. uniflora* Pohl) is a slender shrub indigenous to Brazil and the West Indies. It possesses lanceolate-oblong, dark green leaves and small, pale violet-blue flowers, turning white with age and occurring solitary or in pairs along the leafy branches, and berry fruits.

Manaca occurs in pieces that are frequently longitudinally cut, of variable length and from 1 to 3 cm. thick. Externally the root is dark reddish-brown, longitudinally wrinkled; bark thin, scaly or flaky and adhering to reddish-yellow wood; fracture tough-fibrous; inner surface of bark reddish-brown and of wood, yellowish and radiate as viewed with hand lens; odor disagreeable; taste of bark sweet followed by a sharp bitter sensation; taste of wood slightly bitter.

Description and Physical Properties.—"*Unground Manaca.*—Nearly cylindrical or more or less tortuous, of variable length and up to about 3 cm. in diameter; externally dark brown, wrinkled and with scaly yellowish cork patches, the latter being easily removed from the thin cortex which adheres closely to the wood; inner surface, bark thin, wood light yellowish, hard and finely radiate; fracture short and very tough; taste bitter; odor slight.

"*Powdered Manaca.*—Pale yellow; consisting chiefly of fragments composed of thick-walled lignified fibers associated with rectangular medullary ray cells with thick lignified porous walls and with tracheæ having bordered pores, occasional fragments composed of cork cells with lignified walls or of cortical parenchyma containing a brownish amorphous content or spheroidal starch grains the latter up to about 0.015 mm. in diameter; thick-walled stone cells and occasional rosettes of calcium oxalate." *N. F.*

Miller described a substitute root which he found in samples formerly on the market in amounts ranging from 75 to 100 per cent. It was 7 to 25 mm. thick, yellowish-gray externally with bark twice as thick as that of manaca, neither scaly nor flaky and readily separable from the wood. The wood was softer than manaca, tasteless, of a pale yellow color, with medullary rays plainly visible, without magnification, and pores distinctly visible under a hand-lens. (See *Lilly Scientific Bull.*, 1913, ser. 1, no. 3, p. 115.)

Probably because of confusion among the various substances which are natively known as manaca, there has been some uncertainty as to its composition. Although some authorities have denied the presence of any alkaloid, Lenardson (*In. Dis.*, Dorpat, 1884) found in it a weakly basic substance, *manacine,* besides a fluorescent substance probably identical with gelsemic acid. Manacine is an amorphous bitter principle soluble in water and not precipitated by the alkaloidal reagents. In solution it easily decomposes into *manaceine* and a fluorescent substance probably identical with esculotin (dioxycoumarin).

Uses.—It is not very obvious what evidence of therapeutic value led to the recognition of this drug. Although it has been before the profession for many years, it never has achieved any widespread use. E. P. Bruer (*T. G.*, 1882), as the result of experiments made upon the lower animals, arrived at the conclusion that manaca acts upon the spinal cord, first stimulating, and then abolishing, the activity of the motor centers, the action being shared in by the respiratory centers. All the glands, especially the kidneys, were stimulated by it. In large doses he found it to produce in man lassitude, perspiration, and loose, greenish alvine discharges. Manaca has been used chiefly in the treatment of chronic or subacute *rheumatism* and *syphilis.*

Dose, of the fluidextract, from ten to thirty minims (0.6–1.8 cc.) three times a day.

Off. Prep.—Fluidextractum Manacæ, *N. F.;* Elixir Manacæ Compositum, *N. F.*

MANGANI CITRAS SOLUBILIS. N. F.

SOLUBLE MANGANESE CITRATE

Mangan. Cit. Sol. [Manganese and Sodium Citrate]

"Manganous citrate rendered soluble by the presence of sodium citrate. It contains, when dried to constant weight at 120° C., to not less than 48 per cent. and not more than 52 per cent. of $Mn_3(C_6H_5O_7)_2$ (542.93)." *N. F.*

For account of the sources and general properties of the metal manganese see Part II.

Description and Physical Properties.—"Soluble Manganese Citrate occurs as a yellowish or pinkish white powder, or as translucent scales; odorless, and having a slightly bitter and astringent taste. It is permanent in the air. One Gm. dissolves slowly in about 4 cc. of water; slightly more soluble in boiling water, nearly insoluble in alcohol.

"When strongly heated, it chars and finally leaves a residue which effervesces with acids and imparts an intensely yellow color to a non-luminous flame. An aqueous solution of Soluble Maganese Citrate (1 in 20) rendered alkaline with ammonia water, yields a salmon-colored precipitate on warming with ammonium sulphide T.S. Ten cc. of an aqueous solution of Soluble Manganese Citrate (1 in 20), slightly acidulated with acetic acid and mixed with 2 cc. of calcium chloride T.S., remains clear while cold, but yields a white crystalline precipitate when heated to boiling.

"Separate portions of 10 cc. each of an aqueous solution of Soluble Manganese Citrate (1 in 100), when acidulated with hydrochloric acid, are not more than slightly reddened by potassium thiocyanate T.S. (*iron*); nor rendered turbid at once by barium chloride T.S. (*sulphate*); nor show more than an opalescence with silver nitrate T.S. when acidulated with nitric acid (*chloride*). An aqueous solution of Soluble Manganese Citrate (1 in 20) is slightly acid or slightly alkaline to litmus, but does not redden phenol-phthalein T.S. Mix about 0.5 Gm. of Soluble Manganese Citrate with 5 cc. of sulphuric acid in a porcelain dish previously rinsed with sulphuric acid, protect the mixture from dust, and heat it for fifteen minutes on a water bath; no color darker than yellow develops (*tartrates or other readily carbonizable substances*). An aqueous solution of Soluble Manganese Citrate does not respond to the Test for heavy metals.

"**Assay.**—Dissolve about 0.5 Gm. of Soluble Manganese Citrate, previously dried to constant weight at 120° C. and accurately weighed, in 100 cc. of distilled water, add 50 cc. of solution of hydrogen dioxide, and 10 cc. of ammonia water, and boil the mixture for several minutes. Collect the precipitate on a filter, wash it thoroughly with hot distilled water, dry and ignite to constant weight. The weight of the manganous-manganic oxide (Mn_3O_4) so obtained is not less than 20.23 per cent. or more than 21.92 per cent. of the weight of the salt taken, corresponding to not less than 48 per cent. nor more than 52 per cent. of $Mn_3(C_6H_5O_7)_2$. Each Gm. of manganous-manganic oxide is equivalent to 2.3728 Gm. of $Mn_3(C_6H_5O_7)_2$." *N. F.*

Uses.—Because of the erroneous belief that manganese is a normal constituent of the blood certain French physicians many years ago were led to suggest its use as in *anemia.* Chemists of to-day, however, are agreed that when this element occurs in the blood it is only as an accidental—foreign—substance. The uselessness of the metal clinically was demonstrated by Garrod as far back as 1863. Its continued use is due chiefly to the vigorous advertising of certain proprietary nostrums.

Dose, two to five grains (0.12–0.3 Gm.).

Off. Prep.—Liquor Ferri Peptonati et Mangani, *N. F.*

MANGANI GLYCEROPHOSPHAS SOLUBILIS. N. F.

SOLUBLE MANGANESE GLYCEROPHOSPHATE

Mangan. Glycerophos. Sol. [Soluble Manganous Glycerinophosphate]

"Manganous Glycerophosphate rendered soluble by the aid of citric acid. It contains not less than 70 per cent. nor more than 75 per cent. of $MnC_3H_7PO_6$ (225.04)." *N. F.*

Description and Physical Properties.—"Soluble Manganese Glycerophosphate occurs as a yellowish or pinkish white powder, odorless, and having an acid taste. One Gm. dissolves in 4 cc. of water at 25° C. The aqueous solution is strongly acid to litmus and becomes turbid on heating. Alcohol dissolves the citric acid, leaving a residue which is nearly insoluble in water.

"Add an excess of ammonium sulphide T.S. to an aqueous solution of Soluble Manganese Glycerophosphate; on standing, it yields a salmon-colored precipitate soluble in acetic acid. No yellow turbidity is produced immediately on mixing 5 cc. of an aqueous solution (1 in 20) with 10 cc. of ammonium molybdate T.S. (*phosphate*), but on prolonged standing, or on heating, a yellow precipitate is formed. Heat a powdered mixture of about 0.1 Gm. of Soluble Manganese Glycerophosphate and about 0.5 Gm. of potassium bisulphate; pungent vapors of acrolein are evolved.

"Separate portions of 10 cc. each of an aqueous solution of Soluble Manganese Glycerophosphate (1 in 20) are not rendered more than slightly turbid by barium chloride T.S. when mixed with a few drops of hydrochloric acid (*sulphate*); nor by silver nitrate T.S. after acidulation with nitric acid (*chloride*). Add a few drops of hydrochloric acid and 1 cc. of chlorine T.S. to 10 cc. of an aqueous solution of Soluble Manganese Glycerophosphate (1 in 200) and boil; no reddish color is produced in the liquid by potassium thiocyanate T.S. after cooling (*iron*). An aqueous solution of Soluble Manganese Glycerophosphate does not respond to the Test for heavy metals.

"**Assay.**—Dissolve about 0.5 Gm. of Soluble Manganese Glycerophosphate, accurately weighed, in 100 cc. of distilled water, add 10 cc. of ammonia water and 5 cc. of ammonium sulphide T.S., and boil the mixture until the precipitate formed has become greenish. Allow the precipitate to settle, then transfer it to a filter, wash with hot distilled water containing a few drops of ammonium sulphide T.S., dry the filter and contents and incinerate them in an open crucible, first at a low temperature and then at strong red heat, until the weight is constant. The residue of manganous-manganic oxide (Mn_3O_4) so obtained is not less than 23.7 per cent. nor more than 25.4 per cent. of the weight taken, corresponding to not less than 70 per cent. nor more than 75 per cent. of $MnC_3H_7PO_6$. Each Gm. of manganous-manganic oxide is equivalent to 2.95 Gm. of $MnC_3H_7PO_6$.

Uses.—Whatever therapeutic virtue it may possess is due to its glycerophosphoric radicle. It is used in the treatment of *phosphaturia, deficient nerve nutrition, neurasthenia,* etc. It is rarely prescribed by itself but is an ingredient of the Compound Elixir of Glycerophosphates.

Dose, three to five grains (0.12–0.32 Gm.) several times daily.

Off. Prep.—Elixir Glycerophosphatis Compositum, *N. F.*

MANGANI HYPOPHOSPHIS. N. F.

MANGANESE HYPOPHOSPHITE [Mangan. Hypophos.]

"Manganese Hypophosphite contains not less than 97 per cent. of $Mn(PH_2O_2)_2.H_2O$ (203.06)." *N. F.*

Manganum Hypophosphorosum; Manganous Hypophosphite; Hypophosphis Manganosis; Hypophosphite de Manganèse, Hypophosphite Manganeux, *Fr.;* Unterphosphorigsaures Manganoxydul, *G.*

Manganese hypophosphite may be prepared by the interaction of manganese sulphate and calcium hypophosphite, by mixing a solution containing 1.31 parts of the former with a solution containing 1 part of the latter, filtering out the precipitated calcium sulphate, evaporating and crystallizing.

Description and Physical Properties.—"Manganese Hypophosphite is a pink, granular or crystalline powder; odorless and nearly tasteless; permanent in the air. It is freely soluble in water; insoluble in alcohol.

"An aqueous solution of the salt (1 in 20) is neutral or acid to litmus, and yields with ammonium sulphide T.S. a salmon-colored precipitate of manganese sulphide, soluble in acetic acid. When strongly heated in a dry test tube, the salt evolves spontaneously inflammable hydrogen phosphide and finally leaves a residue of manganous pyrophosphate. When an aqueous solution of the salt (1 in 20) acidulated with hydrochloric acid, is added, drop by drop with agitation, to an excess of mercuric chloride T.S. a white precipitate of mercurous chloride is formed, and, upon the further addition of the solution of Manganese Hypophosphite, the precipitate becomes gray from reduction to metallic mercury.

"Add about 0.5 Gm. of the salt to 5 cc. of acetic acid; no effervescence is produced (*carbonate*). Boil 0.25 Gm. of the salt with 10 cc. of sodium hydroxide T.S.; a white precipitate is formed which gradually acquires a brown color on exposure to the air. The filtrate from this mixture, after being slightly acidulated with hydrochloric acid, boiled for a minute, and then rendered alkaline with ammonia water, yields no precipitate upon the addition of magnesia mixture T.S. (*phosphate*). Dissolve 1 Gm. of the salt in 20 cc. of diluted hydrochloric acid with the aid of heat, and then add 1 cc. of barium chloride T.S.; not more than a slight turbidity is produced (*sulphate*). Dissolve 0.5 Gm. of Manganese Hypophosphite in 10 cc. of hot distilled water, add 10 cc. of solution of hydrogen dioxide and 10 cc. of sodium hydroxide T.S., boil for one minute, then render slightly acid with acetic acid and again warm. Now cool, filter, and add 1 cc. of ammonium oxalate T.S. to 10 cc. of the filtrate; no turbidity is produced within one minute (*calcium*). Pour 5 cc. of an aqueous solution of the salt (1 in 30) into an evaporating dish containing 3 cc. of nitric acid diluted with about 10 cc. of distilled water, and evaporate to dryness on a water bath; the residue meets the requirements of the Test for arsenic.

"**Assay.**—Dissolve about 1 Gm. of Manganese Hypophosphite, accurately weighed, in 30 cc. of boiling distilled water in a 250 cc. measuring flask. Add 25 cc. of solution of hydrogen dioxide and 15 cc. of sodium hydroxide T.S. and heat for ten minutes on a water bath with frequent agitation. Cool, add distilled water to make the volume exactly 250 cc., mix well and filter through a dry filter. Evaporate 25 cc. of the clear filtrate to dryness with 10 cc. of nitric acid, dissolve the residue in 10 cc. of nitric acid and again evaporate to dryness; then dissolve the residue in 10 cc. of distilled water, transfer it to a 100 cc. flask with the aid of a few cc. of distilled water, add a drop of phenolphthalein T.S. and sufficient sodium hydroxide T.S. (free from chloride) to produce a pink color, then add 50 cc. of tenth-normal silver nitrate and agitate the mixture well. Now gradually add zinc oxide (free from chloride) in small portions, agitating vigorously after each addition until the liquid is neutral to litmus. Then add distilled water to make 100 cc., agitate the mixture thoroughly, filter through a dry filter, collect 50 cc. of the filtrate, add 2 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to the production of a permanent red color. Each cc. of tenth-normal silver nitrate used corresponds to 0.003384 Gm. of $Mn(PH_2O_2)_2.H_2O$. Each Gm. of Manganese Hypophosphite corresponds to not less than 286.6 cc. of tenth-normal silver nitrate.

"Preserve it in well-closed containers." *N. F.*

This salt probably possesses no medicinal virtues.

Dose, three to five grains (0.2–0.32 Gm.).

Off. Prep.—Liquor Hypophosphitum Compositus, *N. F.;* Syrupus Hypophosphitum Compositus, *N. F.*

MANNA. U. S.

MANNA

"Manna is the dried exudation of *Fraxinus Ornus* Linné (Fam. *Oleaceæ*). Manna yields not less than 75 per cent. of anhydrous alcohol-soluble extractive, using 90 per cent. alcohol." *U. S.*

Manne, *Fr. Cod.;* Manna, *P. G., It.;* Mana, *Sp.*

The term "manna" is applied to saccharine exudates from various trees. The official variety occurs on the manna ash, *Fraxinus Ornus.* The term "manna" has also been applied to certain substances which have no relation to true manna, notably to the lichen, *Lecanora esculenta,* which at times has suddenly fallen like rain over immense tracts of country, from Persia to the African Sahara. It occurs in the form of small roundish lumps, from the size of a pin's head to that of a pea, yellowish or grayish externally and whitish within, hard, inodorous, and insipid. It has been affirmed that this lichen does not contain starch, but it is really used as an article of food, and good bread is said to have been made out of it. (*Nature,* Jan., 1891.) It is probable that it is the manna of Scripture. In the *Chemist & Druggist,* xcii, p. 750, E. M. Holmes interestingly discusses the source of Biblical manna and expresses the belief that it was a fungus similar to that found in Central Africa in the district of Tanganyika.

Fraxinus Ornus, or the *European flowering ash,* is a tree of moderate height, usually from twenty to twenty-five feet, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, and of a bright green color. The flowers are white, and usually expand with the leaves. They grow in close panicles at the extremities of the young branches, and have a very short calyx with four teeth, and four linear-lanceolate petals.

The manna ash is a native of Southern Europe and is largely cultivated in Italy and Sicily. It yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down and young sprouts are allowed to grow up from the root. (Stettner, *A. Pharm.,* liii, 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface, but, as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the tree yields manna. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies in its character according to the mode of collection, the nature of the season, and the period of the year at which the exudation takes place. For information on manna collection in Sicily, see notes by J. S. Ward. (*P. J.,* 1893, 381.)

Ebert (*Zeit. Oest. Apoth. Ver.,* xlvi, p. 427) has contributed a very able paper, containing citations of all the literature up to 1908, regarding the origin and pharmacognosy of the different varieties of manna. Probably the most comprehensive monograph on the ash manna is that of Tschirch in his large work entitled *"Handbuch der Pharmakognosie,"* Band II, p. 103.

In commerce the following varieties are distinguishable:

1. FLAKE MANNA, or *Manna canulata* (*cannellata*), is the purest variety, and is chiefly obtained from Palermo. It exudes spontaneously, or from incisions, during the hottest and dryest weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk, while the lower incisions yield the inferior varieties. It is in irregular, elongated, flattened, 3-sided pieces, often several inches long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. The entire pieces vary from 10 to 25 cm. in length and constitute the *"long flake manna"* of commerce. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small pieces, generally less than an inch in length, when it is called *"small flake manna."*

2. MANNA IN SORTS, *Manna communis,* is next in quality, and is collected in Italy and Sicily in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Manna in sorts consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter.

Most of the world's supply of manna is yielded by five Italian provinces. Flake manna is produced in Capaci, Geraci and Frassino, these yielding in order 62.15 per cent., 62 per cent., and 47 per cent. of mannite. Manna in sorts is produced in Capaci, Geraci and Castelbuono, yielding respectively 37 to 55 per cent., 37 per cent., and 28 to 30 per cent. of mannite.

Manna is shipped to the United States in cases from Palermo, Italy, only the large and small flake varieties being imported at present. The chief past adulterants for manna have been glucose, sucrose and bread crumbs.

Fictitious Manna.—Attempts have been made to counterfeit manna, but the facility of detection renders such frauds unprofitable, and they are not often practised. R. P. Thomas described (*A. J. P.*, xxiv) a sophisticated manna which differed from the genuine drug both in sensible and in chemical properties, not even containing mannite. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle makers. It may be still further purified by the use of animal charcoal. Thus prepared, it contains less mannite than flake manna, and less of the nauseous principle, but is said not to operate less effectively as a laxative.

Description and Physical Properties.—"In irregular, more or less elongated, flattened, 3-sided pieces; externally yellowish-white; friable; internally nearly white, porous and crystalline in appearance; odor slight; but characteristic; taste sweet, slightly bitter and faintly acrid. Also in irregular masses, consisting in part of brittle or soft fragments from yellowish-white to yellowish-gray in color. The quantity of these yellowish-white fragments must not be less than 40 per cent. of the whole.

"**Assay.**—Proceed as directed under alcohol-soluble extractive, using boiling 90 per cent. alcohol, by volume, and filter rapidly through purified cotton while hot, washing the cotton with boiling alcohol." *U. S.*

Manna has a slight, peculiar odor, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna scarcely so much so as to be disagreeable. Its sp. gr. is 0.834. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold and in its own weight of boiling water. From a boiling saturated aqueous solution it separates in partially crystalline masses on cooling. Alcohol also dissolves it. Boiling alcohol will dissolve 15 parts of manna, and upon cooling deposit beautiful crystals of mannite.

Constituents.—Manna is variable in its constituents. The principal constituent, mannite, ranges from 30 to 90 per cent., the lower percentage being in the poorer varieties and the higher percentage in the better varieties of this drug. Sucrose and invert sugar ranges in amounts from 2 per cent. to 30 per cent., the higher amounts being in the lower grades of manna. There is also present gum, dextrin and traces of citric acid, and *fraxin.* Tanret, after an exhaustive investigation of manna, reported the following carbohydrates as having been identified by him: Mannite, dextrose, levulose, *mannotetrose,* and *mannotriose.* The manna which occurs in tears and distinct fragments is much higher in mannitol than other grades.

The greenish color of certain pieces of manna is produced by *fraxin,* $C_{16}H_{18}O_{10}$, a glucoside closely resembling æsculin. Fraxin crystallizes in colorless prisms, easily soluble in hot water and in alcohol, and has a faintly astringent and bitter taste. By diluted acids it is resolved into *fraxetin,* $C_{10}H_8O_5$, and glucose, $C_6H_{12}O_6$. Even its diluted solutions are fluorescent.

Mannite (*mannitol* or *hexanhexol*) is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_6H_{14}O_6$, and it is considered as belonging to the class of hexatomic alcohols. It was discovered by Proust in manna in 1806. With lime, barium and strontium oxides, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. It does not reduce an alkaline solution of copper oxide; and a test of its purity is thus presented. Emil Fisher has shown that there are three mannites obtainable; the ordinary mannite is the dextrorotatory variety, and is always obtained in the reduction of *a-mannose* with sodium amalgam; a lævorotatory variety is obtained by the reduction of *l-mannose;* and an inactive mannite is obtained from the inactive mannose. These three physical isomers differ slightly in their fusing points and crystalline form. The native variety may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate; pure mannite is now deposited. Another method is to dissolve flake manna in water, precipitate by solution of lead subacetate, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling, the mannite is deposited. (Bonsall, *A. Pharm.*, cxxxiv, 70.) Mannitol occurs in the larch, celery and sugar cane in small amounts. *Agaricus integer* contains 20 per cent. of mannitol. When heated mannitol yields two anhydrides, *mannitan*, $C_6H_{12}O_5$, and *mannide*, $C_6H_{10}O_4$. There are four stereo-isomerides known. They are *dulcitol, sorbitol, talitol* and *iditol.* Dulcitol occurs in a number of plants naturally, the others are synthetic products. Mannitol hexanitrate is described under *Nitrated Alcohols*, Part II. It is said to be gently laxative in the dose of from one to two ounces (31–62 Gm.).

Manna, when long kept, acquires a deeper color, softens, and ultimately deliquesces into a liquid, which on the addition of yeast undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to cause it to pass over into some variety of glucose or fermentable sugar. That which is driest resists this change the longest. It is said that manna recently gathered is less purgative than it afterwards becomes.

A number of exudates from other sorts of trees have from time to time appeared in the markets under the name of manna; these *false mannas* are to-day of no commercial importance but the following are those which in the past have had more or less prominence; for further information concerning these see *U. S. D.*, 20th ed., p. 685.

European False Manna, or *Briançon Manna,* an exudation from the common European larch (*Larix europæa*, or *Pinus Larix*), differs chemically from ordinary manna in containing no mannite. Berthelot (1859) found in it a sugar, *melezitose.*

California Manna, or *Father Picolo's Manna.*—Proust (1806) alluded to a manna mentioned by Father Picolo as being deposited on a species of grass in California. J. U. Lloyd (*A. J. P.*, 1897, 337) believes Picolo's manna to be a saccharine deposit, caused by aphides on *Phragmites communis.* It is apparently still collected by the Indians.

Turkish Manna is a sweet product obtained from *Echinops persica* Fisch., and is obtained by treating the cocoons of a coleopterous insect (*Larinus maculatus*) with hot water, filtering and crystallizing the sugar. From it Berthelot (1857) obtained sugar, trehalose. *Pinus Cedrus,* of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in *phthisis.* (*P. J.*, xiii, 411.) In the neighborhood of Diarbekir, in Asiatic Turkey, a saccharine substance, known as *Diarbekir Manna,* is found on the leaves of dwarf oaks, from which it appears to be exuded. *Quercus Valonea* Kotschy, and *Q. persica* Jaub. et Spach, yield "*oak manna,*" through insect agency.

Persian Manna.—Several manna-like exudates are, or were, produced in Persia. Of these, *Gez* has been identified (*C. D.*, 1894) as being derived from the *Astragalus anisicanthus* (Fam. *Leguminosæ*). *Chirkhest* appears to come from the *Salix fragilis* L. and perhaps other species of willow.

Taranjabin, or *Alhagi Manna,* is yielded by the camelthorn, *Alhagi Camelorum* Fisch., in Persia and Afghanistan, and probably by *Alhagi Maurorum* Tournefort, a leguminous thorny shrub abundant in India—if indeed the two species be distinct. According to A. Villiers, it is nearly pure melezitose. (*P. J.*, 1876.) *Gazanjabin,* or *Tamarisk Manna,* is yielded by *Tamarix gallica* var. *mannifera* Ehrenberg (Fam. *Tamariscinæ*).

Several sweet exudates have been sold in the Indian bazaars. Of these the most important is the *Shirkoit,* or *Oriental Manna.* By Haussknecht it is referred to *Atraphaxis spinosa;* but J. E. T. Atchison states that it is yielded by the *Cotoneaster nummularia* Fisch. et Mey., a tall, stout shrub, whose smaller branches in July become covered with an exudation. *Bamboo Manna,* or *tabashir,* is obtained from the surface of the stems of the *Bambusa stricta* Roxb. (Fam. *Graminæ*).

Australian Mannas.—A manna-like exudation on the *Eucalyptus viminalis* Labill., growing in New South Wales, contains melitose. (See *A. J. P.*, xxviii, 157.) *Lerp* is produced upon the leaves of *Eucalyptus dumosa,* when very small, and sometimes appears spread over large extents of country like a kind of snow. *Myoporum platycarpum* R. Brown, the *sandalwood-* or *dogwood-tree* of Australia, exudes an exceedingly sweet and pleasant manna, which is much used as an article of food, the product containing nearly 90 per cent. of mannite. F. W. Passmore obtained from *Eucalyptus Gunnii* Hook., a sugar termed *melitriose.* (*P. J.*, 1891, 718.) *Blue Grass Manna* is, according to R. T. Baker (*Journ. and Proc. Roy. Soc. New South Wales*, xxx, 1897), produced in the form of nodules at the nodes of the stems of the blue grass *Andropogon annulatus.* It contains numerous crystals of mannite, amounting, according to the analysis of H. G. Smith, to 50 per cent.

Uses.—Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. It is usually prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. Manna forms a combination with iron, which it preserves against oxidation. (See *P. J.*, March, 1873.) Under the name of *dulcinol* a mixture of mannite and common salt has been recommended by Sternberg (*D. M. W.*, 1906, p. 1707) as a sweetening agent in *diabetes.*

Dose, half to one ounce (15.5–31 Gm.).

MASSA FERRI CARBONATIS. U. S.

MASS OF FERROUS CARBONATE Mass. Ferr. Carb. [Vallet's Mass.]

"Mass of Ferrous Carbonate contains not less than 35 per cent. of $FeCO_3$." *U. S.*

Pilula Ferri Carbonatis, *Br.* 1885, also *U. S.* 1870; Pilulæ Ferri Carbonici, Pilulæ Ferratæ Valleti; Pill of Carbonate of Iron, Vallet's Ferruginous Pills, Vallet's Pill Mass; Pilules de Carbonate ferreux, *Fr. Cod.;* Pilules ferrugineuses, Masse Pilulaire de Vallet, *Fr.;* Valletsche Pillen, *G.;* Pillole di Vallet, *It.*

"Ferrous Sulphate, 100 Gm.; Monohydrated Sodium Carbonate, 46 Gm.; Honey, 38 Gm.; Sucrose, in coarse powder, 25 Gm.; Syrup, Distilled Water, each, a sufficient quantity to make 100 Gm. Dissolve the ferrous sulphate and monohydrated sodium carbonate, each, separately, in 200 cc. of boiling distilled water, and, having added 20 cc. of syrup to the solution of the iron salt, filter both solutions, and cool. Place the solution of sodium carbonate in a bottle having a capacity of about 500 cc. and gradually add the solution of the iron salt, rotating the bottle frequently, until carbon dioxide no longer escapes. Add sufficient distilled water to fill the bottle, stopper tightly and set it aside so that the ferrous carbonate may subside. Pour off the supernatant liquid, and, having mixed syrup and distilled water in the proportion of 1 volume of syrup to 19 volumes of distilled water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the water as possible. Then mix the precipitate at once with the honey and sucrose in a tared dish, and by means of a water bath evaporate the mixture with constant stirring until it is reduced to 100 Gm." *U. S.*

"**Assay.**—Dissolve about 1 Gm. of Mass of Ferrous Carbonate, accurately weighed, in 15 cc. of diluted sulphuric acid, dilute the solution with distilled water to about 100 cc., and immediately titrate with tenth-normal potassium dichromate, potassium ferricyanide T.S. being used as indicator. Each cc. of tenth-normal potassium dichromate corresponds to 0.01159 Gm. of $FeCO_3$." *U. S.*

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatus* and *Syrupus Ferri Iodidi.* The U. S. mass of ferrous carbonate is another example of a ferruginous preparation in which the iron is protected from further oxidation by the same means. The process of the U. S. X is nearly the same as that of the previous pharmacopœia. The salts employed are the same as those used for obtaining the formerly official ferric subcarbonate; this was misnamed, as in forming that preparation the carbonate, which is at first precipitated, absorbs oxygen and loses nearly all its carbon dioxide in the processes of washing and drying. When, however, as in the U. S. formula above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbon dioxide during the separation of the precipitate are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water bath. It is essential to the success of this process that the ferrous sulphate should be pure, otherwise some ferric oxide will be present in the product. The process is that of Vallet, of Paris, after whom the preparation is popularly called.

The British Pharmacopœia, 1898, omitted Vallet's mass. (See *Ferri Carbonas Saccharatus.*) Gonnermann prepares *powdered Vallet's mass* by mixing intimately ten parts of milk sugar and five parts of powdered licorice root with sufficient freshly precipitated ferrous carbonate to make, when dried, thirty-five parts, and adding enough powdered licorice root to make the whole weigh forty parts. (*Ph. Post,* 1893, 238.)

Properties.—The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray color, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of ferrous carbonate. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Uses.—The U. S. mass of ferrous carbonate, or Vallet's ferruginous mass, is an excellent preparation for use in simple *anemia* and *chlorosis.* Its chief merits are its unchangeableness, its freedom from astringency, and its ready solubility in acids.

Dose, in pills, from three to five grains (0.20–0.32 Gm.), after meals.

MASSA HYDRARGYRI. U. S. (Br.)

MASS OF MERCURY Mass. Hydrarg. [Blue Mass Blue Pill]

"Mass of Mercury contains not less than 32 per cent. nor more than 34 per cent. of Hg." *U. S.*

Pilula Hydrargyri, *Br.;* Mercury Pill; Pilulæ Hydrargyri, *U. S.* 1870; Pilulæ Cœruleæ, Massa Cœrulea; Pills of Mercury; Mercurial Pill; Pilules mercurielles simples, *Fr. Cod.;* Pilule de Mercure, Pilules bleues, *Fr.;* Mercurialpillenmasse, *G.*

"Mercury, 33 Gm.; Oleate of Mercury, 1 Gm.; Glycyrrhiza, in very fine powder, 10 Gm.; Althea, in very fine powder, 15 Gm.; Glycerin, 9 Gm.; Honey of Rose, 32 Gm.; to make 100 Gm. Triturate the oleate of mercury in a warm mortar, gradually add the mercury, then introduce a small amount of honey of rose, and triturate the mixture until globules of mercury are no longer visible under a lens magnifying ten diameters. Incorporate the remainder of the honey of rose and the glycerin, gradually add the glycyrrhiza and althea, and continue the trituration until the mass is homogeneous." *U. S.*

"Mercury, 40 *grammes;* Confection of Roses, 60 *grammes;* Liquorice Root, in powder, 20 *grammes.* Triturate the Mercury with the Confection of Roses until metallic globules are no longer visible; add the Liquorice Root; mix to form a mass." *Br.*

"**Assay.**—Place about 0.5 Gm. of Mass of Mercury, accurately weighed and rolled into one or two pills, in a Kjeldahl flask of about 300 cc. capacity. Add 10 cc. of sulphuric acid, and heat on a water bath during ten minutes, gently agitating at frequent intervals to disintegrate the mass. Insert a small funnel in the neck of the flask, and slowly add 10 cc. of nitric acid. Heat the mixture with a Bunsen burner, at first gently, gradually increasing the heat until the solution is colorless or only slightly yellow, adding more nitric acid if necessary, and keep the funnel in the neck of the flask during heating. Allow the solution to cool sufficiently, and add carefully through the funnel about 30 cc. of distilled water, rinsing the stem of the funnel with a few cc. of distilled water and allowing the rinsings to run into the flask. Then add to the warm solution, potassium permanganate T.S. until a slight pink color persists. Cool the solution, discharge its color by the addition of just sufficient oxalic acid T.S., add 3 cc. of nitric acid and 2 cc. of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium thiocyanate to a permanent reddish color. Each cc. of tenth-normal potassium thiocyanate corresponds to 0.01003 Gm. of Hg." *U. S.*

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater proportion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into mercurous oxide, and that this is the ingredient upon which the activity of the pill depends. Harold Senier (*P. J.,* 1876) analyzed a number of samples of blue mass, with the view of determining the amount of metallic mercury and of mercurous and mercuric oxides. The results showed that the latter gradually increased in quantity with the age of the blue mass, which, 18 hours after preparation, contained but a trace of mercurous oxide; after three months, 0.24 per cent. of mercuric and 0.62 per cent. of mercurous oxides were obtained, and in another sample, 0.44 and 1.60 per cent., respectively. After two years, 1.80 per cent. of mercuric and 4.22 per cent. of mercurous oxides were present. It is obvious that the effects of the preparation are not due to the oxide. The U. S. VIII provided a test which limited the quantity of mercurous oxide and proved the absence of mercuric oxide; it will be difficult for the ordinary "blue mass" of commerce to withstand these requirements: "If a portion of the Mass be triturated in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of *mercurous oxide*). If another portion of the Mass be digested with warm, diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hydrogen sulphide T.S., or by stannous chloride T.S. (absence of *mercuric oxide*)." *U. S. VIII.*

All agree that the efficacy of the preparation is proportionate to the extinguishment of the mercury; in other words, to the smallness of the metallic globules. This may be effected by trituration with various substances, and manna, syrup, honey, licorice, mucilage, soap guaiac, and extract of taraxacum have been recommended, among others, for this purpose; but the oleate of mercury has been adopted by the U. S. P. as less open to objection than any other. The mercury is known to be completely extinguished when, upon rubbing a portion of the mass with the end of the finger upon a piece of paper, no globules appear, or the extinguishment may be more accurately judged by the official microscopic test. Powdered licorice root and powdered marshmallow root are added in order to give due consistence to the mass. It is possible for the apothecary to make moderate quantities extemporaneously with no other appliances than the mortar and pestle. As the trituration requires to be long continued, which renders the process very laborious, when conducted on the large scale it is customary to prepare the mass by machinery. A machine for preparing blue mass, capable of being worked by hand or steam power, invented by J. W. W. Gordon, of Baltimore, was at one time in extensive use. (*A. J. P.*, xxi, 6.) A more modern method is to extinguish the mercury in the original iron cylinder, or "flask" in which mercury is shipped, by mechanical agitation with the oleate of mercury and honey of rose, and then incorporate the other ingredients in a mixing machine. The preparation slowly changes color upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.

The blue pill is sometimes wanted in the state of powder, but, from its peculiar constitution, it is not eligible for reduction to this form, as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is likely, when pulverized, to attract moisture from the air. Chas. Bullock recommended the following method of preparing a powder which, as nearly as possible, represents the blue pill, in reference to its therapeutic effects:

Powdered Blue Mass.—Take of finely powdered Elm bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, until the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting cloth.

Uses.—Blue mass has the therapeutic properties of the mercurials (see *Hydrargyrum*), but is to-day chiefly employed for its cathartic action. It seems to be somewhat less irritant than calomel and the purgation caused is less frequently accompanied with griping. When used as a cathartic it is sometimes necessary to follow it after some hours with a saline.

Dose, as an alterative, one to three grains (0.065–0.2 Gm.), as a laxative, from five to fifteen grains (0.32–1.0 Gm.).
